CODE

CODE (Lat. *codex*, manuscript, originally designating any writing, but afterward used specially for a law, or some form prescribed by law; hence *codicillus*, the diminutive of *codex*, was a supplement to a will), in jurisprudence, a compilation of laws made by public authority. In a popular sense it is understood to be a complete body of law, or if it relate to a particular subject, that it is to that extent complete; in other words, that if it be intended as a general system of laws, it supersedes all previously existing laws not embraced in it; and so of a partial code, that so far as it goes it excludes all other sources of decision. This is however erroneous. No compilation of laws was ever made which was so complete as to provide for all the cases that could arise. Positive or statute law is comparatively a small part of the laws of any country. There is always a law of custom growing out of the habits and peculiar circumstances of a people. Legislative authority may take hold of certain principles developed by custom and give to them the form of written law, but it will still be incomplete, and the deficiency must be supplied by the same process which in the first instance brought into exercise those principles which have been incorporated in the written law. A code of laws contains no inherent power of further production. Analogies may be furnished for many cases, yet even these will yield to the imperious force of changing circumstances and necessities. Other cases must incessantly occur, for the determination of which no analogy is furnished in the written law, and in these the constitution of society, from which a law of custom is continually germinating, must be the sole authority. Still more erroneous would it be to suppose that in any community a code was ever preënacted as the basis of social organization and civil rights, and that the national character was derived therefrom. The reverse of this has been the uniform course, so far as we have historic records; and it is only when these are deficient that the unsupported hypothesis has been substituted whereby a lawgiver is supposed to have moulded a whole people by his legislative enactments. There have indeed been governments, especially in eastern countries, which have had unlimited power to make and unmake laws without regard to the rights or wishes of the people; but this is only saying that a people may be subject to such a despotism as to be virtually without law except the arbitrary will of an autocrat. Under a despotical government the laws may be enforced for a time, however unacceptable to the people; yet there is a limit beyond which no sovereign can go without the danger of revolution, as when he attempts to interfere with the ancient usages of the mass of the people. The form of the government may be changed, and political rights abrogated; but customs generally prevailing in domestic life or social relations, or involving religious faith, if such customs have become venerable by their antiquity, cannot be wholly suppressed except by the entire subjugation of the people to a foreign enemy, nor even then unless by a perfectly merciless war, as when the Britons were conquered by the Anglo-Saxons. The common version as to the mode in which laws were established in the Grecian states is in great part fabulous. As to Crete we have no authentic records remaining; but as to Sparta, Thirlwall and Grote maintain that Lycurgus, to whom is commonly attributed the formation of the constitution and laws of that state, in fact introduced no new principles in either the political or social organization of the people, but merely brought into systematic arrangement the usages previously existing, with some modifications or additional provisions essential to the conservation of the peculiar form of nationality already existing, and by a public enactment with a religious sanction gave permanence to the entire system as digested by him. The double lines of kings, the *gerusia* or council of elders, the assembly of the people, even the ephors, with

less authority than they afterward acquired—all these existed before the legislation of Lycurgus; so also the distinction between Spartans and Laconians, and the still greater distinction between the former and their serfs the helots. Usages had grown up corresponding to this isolation of a small number in the midst of a numerous subject people, and it was for the carrying out more efficiently the design of these usages that Lycurgus prepared the code which thenceforth became the fixed law of Sparta. In like manner the Athenian state was harmonized by the laws of Solon, but more particularly by his constitution of political powers. The archonship, the areopagus, and the council of 400 were constituent parts of the government before his revision of the laws. The assembly of the people had also taken some part in public affairs, but in a rude, irregular manner, without any fixed authority or prescribed mode of proceeding. Solon constituted it the chief legislative body, yet with the restriction that they were to consider only what was proposed by the senate. This restriction was afterward evaded, because the assembly could modify any proposition that came before them without sending it back to the senate for approval; and again, when a law was desired by the people, any one could present it to the senate and procure the preliminary action necessary for bringing it before the people. A still greater popular power was conferred by the judicial authority given to the dicasteries, which were composed of a large number of citizens, drawn by lot, presided over by one of the archons. The number of jurors in important cases was very large, sometimes including the whole body of citizens qualified to serve. The other laws of Solon corresponded with this development of the popular element. All citizens over the age of 20 were entitled to speak and vote in the assembly, and to sit as jurors in the dicasteries; trade and manufacturing industry were encouraged, and intercourse with foreigners was promoted by giving to them greater privileges than were allowed by any other Grecian state. Still it appears that all his legislation was in consonance with the spirit of the people, and the particular laws were probably for the most part reënactments of customs already existing, but with some wholesome restraints or new provisions intended for the maintenance of the largest liberty within the proper limit of civil order.—The same principle is again exhibited in the Roman laws of the twelve tables. The account given by Livy is, that commissioners were sent into Greece to examine the laws and institutions of the principal states, and to transcribe the laws of Solon; that after their return, another commission (the decemvirs) was constituted to draw up a code of laws, the result of which was the compilation of the twelve tables. But the laws of Solon were certainly not incorporated in the code of the decemvirs, nor, so far as we are able to judge of the original from the fragments remaining and the commentaries of Roman writers, was that code transplanted from any foreign state. Acquaintance with the laws of other countries might have suggested a systematic form, perhaps have furnished some analogy for a rule in cases not otherwise provided for; but the law of the twelve tables was essentially Roman, and was undoubtedly compiled from preëxisting sources peculiar to the Roman people. As in the legislation of Solon, so in that of the decemvirs, one great object was to quiet political dissensions between the aristocracy and common people. It had been a subject of complaint by the people that the consuls, who had the whole judicial power, decided arbitrarily—not that there was no law, but no sufficient sanction to prevent perversion; and the remedy proposed was, that the laws should be made certain, and that the patrician magistrates should be compelled to conform thereto (*quo omnes uti deberent*), which it was supposed would be accomplished by having the laws written out and published. This proposition was what led ultimately to the appointment of the decemvirs, and the laws which they reported were engraved first on wood and exposed in the forum; after the destruction of the city by the Gauls they were engraved on brass, and are mentioned as still existing in public view as late as the 3d century of the Christian era. It is often said that the twelve tables constituted the basis of the Roman law for ten centuries; but this is in no proper sense well founded. Themselves founded on custom (*mores majorum*), they constituted but a fragment of the vast body of law elaborated by the energizing force of social and political elements in all the diversified relations incident to a free and prosperous commonwealth. The judicial discretion of the prætors (*jus æquum*), the opinions and writings of jurists (*auctoritas prudentum*), the rescripts of the imperial court, and the decisions of cases (*sententiæ receptæ*), were the voluminous exponents of the Roman common law, founded not upon legislative enactments (*leges*), but upon custom (*mores*). The edicts of the prætors, in which it was allowed annually to incorporate new applications of the *jus æquum*, were in the reign of Hadrian revised by Salvius Julianus, and the revision was confirmed by the imperial council, from which time it remained substantially unchanged. In a limited sense this might be called a code of the equitable laws administered by the prætor. Legislative ordinances, or what we should call statutes (*leges*, *plebiscita*, and *senatus consulta*), made comparatively little addition to private law; they related chiefly to political rights and to the forms of judicial administration. So the decrees of the senate and the edicts of the emperor, after the popular government was subverted, during a long period related chiefly to public affairs; and even when they related to private law, it was rather in the nature of a decision or declaration of the law than any new provision. The distinction between legis-

lative and judicial functions was little observed. The rescripts of the emperor (or of those authorized to make answers in his name) for the resolution of doubtful cases, the decrees in actions brought by appeal before the imperial court, and the edicts, as well those relating to the administration of the government as for the regulation of private rights, were all embraced under the general designation of *constitutiones principum*. The great number of these constitutions, and the crudity of many of them, rendered compilations and commentaries indispensable. Among these the principal are the imperial decrees or decisions collected by Paulus; "Rescripts of the Divi Fratres," collected by Papirius Justus; rescripts of Hadrian, compiled by Dositheus; the collection by Ulpian, in his work *De Officio Proconsulis*, of all the ordinances issued against Christians; and lastly, two general collections (*codices*) of constitutions from Hadrian to Constantine, the one by Gregorius, the other by Hermogenes (the latter a supplement to the first), both of which consisted chiefly, as is understood, of rescripts. All of these were private compilations, and do not strictly come under the definition of codes as given at the beginning of this article. The *Codex Theodosianus*, published A. D. 438, by order of Theodosius the Younger, was a compilation of all the edicts of the emperors which were deemed important, and also many of the rescripts. This was a work of great importance, not merely as the initiative of the great work of digesting the whole Roman law afterward completed by Justinian, but for its influence upon several of the Germanic nations, by whom it was adopted or in some degree made the basis of their laws before the revision had been made which is now known by the name of *Corpus Juris Civilis*. The compilations made by order of Justinian in 528–'35, the Institutes, Pandects, and code, and the new constitutions which were published after his death in 565, have been described in the article Civil Law. In the same article will also be found an account of three of the barbaric codes, viz.: the edict of Theodoric, king of the Ostrogoths, in 500; the *Breviarium Alaricianum*, issued by Alaric II., king of the Visigoths, in 506; and the *Lex Romana* of the Burgundians, published in 517–534. All of these were intended chiefly for Roman subjects. But there were also distinct laws for the barbarians themselves, which it will be proper to notice more in detail.—First as to the Franks. There were two tribes, one called Salian (probably from the river Sala, or Yssel, upon which they were first established), the other Ripuarian (from the Latin *ripa*, the name expressing their location upon the banks of the Rhine). These tribes had separate compilations of laws, which continued in force even after the union of the two tribes under Clovis. Of the Salic law our knowledge is derived from manuscripts still extant, most of which are an unmixed Latin text, but others have an intermixture of Germanic words. The latter are entitled *Lex Salica antiqua* (or *antiquissima*, or *vetusta*), the other *Lex Salica recentior* (or *emendata*, or *reformata*). M. Wiarda, in a work entitled *Histoire et explication de la loi salique*, has proved that none of the compilations are of an earlier date than the 7th century, and that the manuscripts containing Germanic words and purporting to be the more ancient are in fact later in time than the others. The laws themselves he supposes to have been compiled after the Franks had become established in Belgium, and that they were originally written in Latin. He also concludes that they were not published as a code by public authority, but were compiled from customs and judicial decisions; and that they do not constitute all the laws of the Salian Franks. The earliest historical notice of any such compilation is in the 8th century, in a work called *Gesta Francorum*. Guizot (*Histoire de la civilisation en France*) deduces from a critical examination of all the manuscripts that the law is essentially penal. It contains 343 penal articles, and only 65 upon all other subjects. The nature of the crimes and punishments which are specified indicates an exceedingly rude condition of society. There is no generalization, but a chaotic mingling together of the various individual cases of crime that might occur in an uncivilized community, without definition, classification, or any arrangement. One peculiarity is observable, which indeed may be found in the laws of all the Germanic nations at an early period, viz., the extreme mildness of punishments as respects free men, whether Franks or Romans. Pecuniary composition, *Wehrgeld* or *Wiedergeld* (prohibition money), was the only penalty prescribed by the Salic law, and this only as a substitute for the right of the injured party to take personal vengeance; but if accepted, the law merely fixed the amount. In respect to slaves it was different; they were subject to cruel corporal punishments, imprisonment, and death. Another peculiarity, which also belonged to the laws of other tribes, was the mode of proof in judicial trials. This was by the oath of compurgators or conjurators, that is to say, a certain number of the friends of the accused who deposed that he had not done what was imputed to him; and on the other hand, conjurators could be produced by the accuser. There was no examination of witnesses nor discussion of the facts, but a simple attestation under oath of the truth of the charge or a denial thereof. The laws of the Ripuarian Franks were essentially the same as those above described, with only the following distinguishing circumstances: 1, that there is more of precision and legislative form, and that the subjects are less exclusively penal; 2, that the mode of proof by compurgators or conjurators is more distinctly regulated; 3, judicial combat is recognized as a mode of deciding controversies. This cus-

tom seems to have been intended as a check upon the right of private revenge. If the offended party insisted upon personal vengeance, then it was to be subject to certain terms, and was to be in the presence of witnesses. The Ripuarian laws, it is supposed, were compiled in the 7th century. The laws of the Burgundians are of an earlier period, probably between the years 468 and 534, the latter being the date of the final conquest of the Burgundians by the successors of Clovis. The chief characteristic of those laws is that they apply to Romans and Burgundians alike, and that civil rights and procedure are more prominent than in the laws of the Franks, probably by reason of the great interfusion of Roman law.—The capitularies of Charlemagne and several of his successors have been commonly classed among compilations of laws. They are, in truth, the acts of the government in all its functions, including instructions to magistrates, financial regulations, political, civil, and canonical legislation, judicial decisions, even moral precepts, and propositions or questions for consideration. Guizot has arranged the acts of Charlemagne into 1,150 articles. Of these the greater proportion belong to canonical legislation, including under that term the acts of councils and the ordinances of the emperor in relation to affairs of the church. The next most considerable subject is political legislation, relating to administrative offices, courts, and police, and is contained in 293 articles. Penal provisions are numerous, but differ little in character from the previous penal laws of the Ripuarians, Lombards, and other barbarian nations who had become subjects of Charlemagne. There is one exception, in the severity with which he punished the conquered Saxons. Legislation concerning private rights is comparatively inconsiderable. Among the capitularies are some additions to the ancient laws, as the Salic and Ripuarian, the laws of the Lombards, Bavarians, &c.; there are also extracts from these laws, which were probably intended for some particular purpose. It is said that a revision of the Salic law, and of the laws of the Lombards and others, was made by order of Charlemagne, but only fragments of such revision appear in the capitularies. In fact, the capitularies themselves are but fragmentary, many of them being imperfect, and others being referred to which are lost. The most complete edition of the capitularies was published by Baluze (Paris, 1677).—The laws compiled by Alfred the Great in the 9th century have been celebrated as the supposed origin of the peculiarities of the English common law. Trial by jury is commonly referred to this monarch as if first introduced by him. But this is certainly not sustained by authentic evidence. It was a familiar principle in the usages of all the Germanic nations that a free man should be tried only by his peers. In the laws attributed to Alfred we find the same general characteristics as in those of the Franks and other Germanic nations, pecuniary compositions for every species of crime, proof by compurgators, and the like. A law was indeed enacted by Alfred, making wilful murder a capital offence, but it seems not to have been enforced. There is one provision in these laws which may have originated in the humanity of the sovereign, but more probably in the regard which the Anglo-Saxons had for a man's house as being sacred, which feeling has been transmitted to their descendants, and exists to this day. If a man who had committed an injury should keep within his own house, his adversary might besiege him for seven days without attacking him; but if within that time the besieged person should be willing to surrender himself and his arms, his adversary might detain him 30 days, but after that must restore him safe to his kindred, and be content with the compensation prescribed by law. Trial by ordeal and other superstitious methods appear to have been frequent among the Anglo-Saxons. Judicial combat, if in use at all, was seldom resorted to until the Normans substituted it in place of compurgation.—Coming down to a more recent period, we find a peculiar law of custom developed under the feudal system, especially in France. In the southern part of that monarchy, which had been occupied by the Visigoths and Burgundians, the Roman municipal institutions, judicial forms, and rights of property, were to a considerable extent preserved. That part of the country was for that reason called *pays du droit écrit*. Yet even here, in some districts, many peculiar customs (*droits coutumiers*) were established in the feudal anarchy. In other provinces, especially the northern, the Roman law was almost entirely lost, at least was no longer distinguishable, and a new system succeeded, of various character, according to the degree of independence maintained by the great feudal lords; and these provinces were designated as *pays du droit coutumier*. The laws of Normandy are the most important on account of their bearing on the English law of landed property. The customs of the county of Paris were next in importance, as they were regarded as precedents in other districts. Many of these local systems were collected in the *Établissements de St. Louis*. In the reign of Charles VII., in 1453, it was decreed by the assembly of the states that all customary laws should be reduced to writing. This brought into distinct and recognized legal existence a vast number of systems, a collection of several hundred of which has been made by Bourdot de Richebourg (*Coutumier général*, Paris, 1724). This diversity, instead of being relieved by general legislation as the authority of the crown increased, was only made more perplexed by *ordonnances* not founded upon comprehensive principles, and therefore having no tendency to assimilate the heterogeneous elements before existing. Collections of these ordonnances were repeatedly made, some of

which received the inappropriate designation of codes; as the *Code Henri*, made by Brisson in the reign of Henry III.; the *Code Murvillac* or *Michau*, under Louis XIII. (1629), relating to judicial procedure; and the *Code Louis XV.*, by Chaussepierre, containing the ordonnances from 1722 to 1740. Several comprehensive ordonnances, which were in fact codes of laws relating to particular subjects, were enacted in the reign of Louis XVI. But the necessity of a general compilation, and the assimilation of all the different systems into a homogeneous jurisprudence for the use of the whole nation, became more and more pressing, till the revolution paved the way for its accomplishment. It was early the subject of discussion, and projects were reported by Cambacérès in 1793 and 1795, which, though incomplete in details, and on the whole unsatisfactory, yet furnished a perspicuous and well arranged outline. By a consular decree, Aug. 12, 1800, a commission was constituted "to compare the order which had been followed in the preparation of the projects for a civil code hitherto published, to determine the plan which the commissioners should think best to adopt, and to discuss the chief principles of civil legislation." Portalis, Tronchet, Bigot de Préameneu, Maleville, and the minister of justice were the commissioners. In 1801 they reported a draft of a civil code, which was submitted to the court of cassation and other courts of appeal, and with the reports of the judges was finally brought before the council of state, in which Napoleon (then first consul) presided in person. The discussion, which was consecutive and thorough, may be found in a work entitled *Conférence du code civil, avec la discussion particulière du conseil d'état*, &c. (Paris, 1805). In the discussion and adjustment of the code, Tronchet, Rœderer, Portalis, Thibaudeau, Cambacérès, and Le Brun were the most conspicuous. Of these, Tronchet was the most regarded by the first consul for profound and enlightened views; Le Brun was the best qualified as a *rédacteur*. In the same manner the other codes were reported, discussed, and amended. The whole revision was finally adopted under the title of *Les cinque codes*, consisting of the civil code (which, as the first in order, and most important, was distinguished by the appellation of the *Code Napoléon*), the code of criminal procedure, penal code, code of civil procedure, and code of commerce. Another was added by Charles X. (1827), entitled the *Code forestier*, which is a collection of laws relating to the administration of the wood lands belonging to the king, or to cities, villages, &c.; and the whole is now published under the title of *Les six codes*. Of the merits of this great work we have sufficient evidence from the fact that it still continues, with but little change, to be the law of France, notwithstanding the subversion of the government by which it was established. The extent of its influence upon the laws of other countries has been very great. Civil codes modelled after the *Code Napoléon* were promulgated in the Two Sicilies in 1819, the Netherlands in 1822 and 1837, Hayti in 1826, Sardinia in 1837, the Swiss cantons from 1819 to 1855, and Bolivia in 1843; and everywhere the Latin races appear to be following these examples.—In Germany, until a recent period, the laws, both civil and criminal, have been in a state of great confusion. In 1532 the statutes commonly known as the *Carolina Criminalis* were enacted by the emperor Charles V. for the regulation of criminal proceedings. Prior to that time the law of the empire relating to crimes was threefold: 1, the Germanic, contained in the ancient barbaric codes and subsequent local usages; 2, the provisions of the Roman law in the compilations of Justinian, particularly the *Libri Terribiles* of the Digest, and the 18th title of the Institutes; 3, the various penal provisions of the canon law (*Corpus Juris Canonici*). The *Carolina Criminalis* purported to be "a simple instruction for unlearned judges, to teach them how to proceed in criminal cases." It did not supersede the previously existing laws, but referred to them, sometimes defining what was obscure, and fixed punishments with more exactness, but more particularly regulated the form of criminal proceedings. Being in form didactic rather than statutory, a large license was taken by judges in administering the law as thus prescribed, and uncertainty still prevailed. The revision of the Prussian laws known as the *Code Frédéric*, published 1749–'57, revised after 1780, but not put in force till 1794, was intended to obviate, according to its preface, 1, the difficulties of the Roman codes; 2, the disputes of the commentators; 3, the contradictions of Roman and German law. Like the Institutes, it divides the subject into the law of persons, of things, and of obligations. The penal laws have since been repeatedly revised. In 1826 a commission was appointed to prepare a new penal code, in pursuance of which six different projects were presented and discussed at various times, during a period of 25 years; and the code which is now in force was finally adopted in 1851, and has been highly praised. Other German states made efforts toward codification in the last century. A criminal code for Bavaria was promulgated in 1751, and for Austria in 1768, and again in 1786. In the latter country a civil code was produced in 1811, founded in great measure on the Prussian code; and a code of criminal procedure was published in 1852, which adopts the classification of offences contained in the French penal code. In Bavaria a penal code prepared by Feuerbach was adopted in 1813, which was received with such favor as to be accepted by several other states.—In Russia a commission, which originated with Peter the Great, reported in 1832 the *Svod zakonov*, which became the exclusive source of law in 1835. This comprises eight codes, devoted respectively to—1, the state and imperial family; 2,

public services; 3, finance; 4, the classes of persons; 5, civil law; 6, administration; 7, police; 8, penal law. It contains about 38,000 articles, each of which is referred to some preëxisting ordinance.—In the United States the first experiment at a legislative remodelling of the entire law was made in Louisiana. That state was originally a French colony; it was afterward ceded to Spain, when the Spanish law was introduced, but again reverted to the French, and from them was acquired by the United States. The confusion of laws introduced by these numerous changes of government made a revision necessary, and a code was prepared and adopted in 1806–'8, which did not, however, supersede the ancient laws, except so far as they conflicted with it. A further revision was found necessary, and in 1822 commissioners were appointed for that purpose, who reported a complete civil code, which was adopted in 1824. Mr. Edward Livingston, one of the commissioners, and who is understood to have had the chief part in the compilation, had been familiar with the common law, and introduced from it many valuable provisions, though the basis of the work was mainly the French civil code. Mr. Livingston also reported a penal code, which was received with favor by the legislature, but not formally adopted. It brought to its author great reputation, especially in Europe. A penal code and code of procedure have since been adopted. The most important, however, of the attempts at codification which have been made in the United States are those of the state of New York, which had their origin mainly in the able and persistent efforts of David Dudley Field, which he began in 1839, by a public letter on the subject addressed to Gulian C. Verplanck, then a state senator, and continued by a series of addresses to legislative committees, of articles in the newspapers, and of pamphlets. The result of this agitation was that the revised constitution of New York, adopted in 1846, had two separate provisions in relation to codification. The first directed the appointment of three commissioners to reduce into a code the whole body of the law of the state, or so much thereof as might be deemed expedient. The other directed the appointment of three other commissioners to revise the rules of practice and pleadings in courts of record. Both commissions were filled by the legislature in 1847. The practice commissioners made a partial report on Feb. 29, 1848, containing an incomplete code of civil procedure, in such shape as to cover the principal reforms proposed in the practice of courts of record in civil cases, and this report was immediately adopted by the legislature. The complete codes of civil and criminal procedure were not reported until Dec. 31, 1849, and were never adopted by the legislature, although some portion of the amendments suggested by the commissioners were gradually incorporated by legislation into the text of the original and incomplete code enacted in 1848. On April 6, 1857, the legislature created a new commission to prepare codes of all the law not covered by the reports of the practice commission, and appointed David Dudley Field, William Curtis Noyes, and Alexander W. Bradford the commissioners, for a term of five years, which was afterward extended for three years further. They reported a political code, a penal code, and a civil code. These codes have not up to the present time been adopted by the legislature of New York; and indeed, although reported by committees, the legislature has always been too much occupied with special legislation to give the necessary time for their consideration. The code of civil procedure, in whole or in part, has been adopted into the laws of 23 states and territories of the Union, viz.: New York, Ohio, Indiana, Kentucky, Missouri, Wisconsin, Iowa, Minnesota, Kansas, Nebraska, Nevada, California, Oregon, North Carolina, South Carolina, Alabama, Washington, Montana, Idaho, Dakota, Wyoming, Utah, and Arizona. It has also been adopted for the consular courts of the United States in Japan. The code of criminal procedure has been adopted in ten or more states and territories. In California a code commission created by the legislature reported in January, 1872, a complete series of codes framed upon the basis of the projected New York codes, all of which were adopted by the legislature, to take effect on Jan. 1, 1873. This consisted of a political code, a civil code, a penal code, and a code of civil procedure; the practice in criminal cases being regulated by the penal code. The territory of Dakota in 1864 also adopted the civil and penal codes of the New York commissioners. The principal feature of the code of civil procedure thus adopted in New York and other states was the entire fusion of law and equity by which the same principles were for the first time in the history of New York, or of any other states inheriting the English practice, applied to all species of actions. The courts of Pennsylvania had from the organization of the state decided actions at law upon the principles of equity, but they have never been clothed with all the powers of courts of equity as defined by the English practice. The union in one tribunal of all the powers belonging to a court of chancery as well as to a court of common law, and the application of all the principles of both systems to every controversy arising before the courts, was therefore an absolute novelty in 1848 in any state or colony founded by Englishmen and inheriting English law. The practice in English law courts being entirely different from that of courts of equity, it was necessary to devise a single and homogeneous system including the most useful parts of each form of procedure, and this was done by the code of civil procedure reported by the New York commissioners. Without this preliminary reform it would have been almost im-

possible to frame an intelligible code of law for an English-speaking community, inasmuch as many elementary questions were disposed of in one court upon precisely the opposite principles from those enforced by the other court. This difficulty being removed, however, it has been found as practicable to reduce the common law of England to the form of a code as the law of any other country. The civil code, defining the rights of individuals as between each other, is the one most interesting to the public at large. This code, as reported in New York and adopted in California and Dakota, consists of three principal divisions, viz., persons, property, and obligations, and a fourth or supplemental division containing general provisions applicable to more than one of the chief divisions already mentioned. Under the head of "Persons" are treated the subjects of personal rights and relations, including marriage, parentage, guardianship, &c., with the rights and duties growing out of them. Under the head of "Property" the rules, conditions, limitations, and incidents of ownership in both real and personal property are stated, including the modes of transfer by grant, will, inheritance, and otherwise. Under the head of "Obligations" the interpretation, transfer, and extinction of obligations are treated, together with the entire subject of contracts, under which special title are set forth the rules governing the creation, interpretation, and extinction of contracts, and the particular rules governing sale, exchange, deposit, loan, hiring of property, personal service, carriage or transportation, trusts or confidential relations, agency, partnership, insurance, indemnity, guaranty, liens (including pledge and mortgage), and negotiable instruments. Under the fourth division there are five titles: 1, relief, including the law of damages, injunctions, specific performance, &c.; 2, debtor and creditor, including fraudulent transactions, and assignments for the benefit of creditors; 3, nuisance; 4, maxims of jurisprudence; 5, definitions. The civil code of California has, in addition to the matter contained in the New York code, extensive and detailed provisons regulating the management of corporations, and the business of mining, which has in that state an exceptional importance.—The subject of codification has for many years been under discussion in England and the United States, especially since the time of Jeremy Bentham; but the codes framed by the New York commissioners were the first in which any real attempt was made to embody the old law of any English-speaking community. Since their publication the expediency of codification has become a subject of renewed interest in England, and the adoption of a code has been urged not only by private individuals but by members of the present government (1873), with every prospect of ultimate success. A commission was some time since appointed in England to prepare a digest of the existing law as the basis for the construction of a code, and the result of its efforts is generally understood to be strong conviction in the minds of the leaders of the legal profession that a complete code rather than a mere digest must become an absolute necessity.

CODEIA (Gr. *κώδεια*, head of poppy), an alkaloid found in opium, in which it exists combined, like morphia, with meconic acid. It has the formula $C_{35}H_{20}NO_5$. It is soluble in water, alcohol, and ether, but is insoluble in alkaline solutions. It combines with acids to form crystallizable salts. (See OPIUM.)

CODEX (Lat.), in Roman antiquity, originally the trunk of a tree, afterward applied to the wooden tablets smeared with wax which were used for writing. At a later period it became the name of all large manuscripts (*codices manuscripti*), as the works of the historians and poets; and under the emperors and subsequently, it designated collections of civil and ecclesiastical laws. Of the last, the oldest and most celebrated are the *Codex Theodosianus*, the *Codex Justinianus*, the *Codex Canonum Ecclesiasticorum*, belonging to the time of Pope Innocent I., and the *Codex Canonum Ecclesiæ universæ*, revised by the monk Dionysius about 527. Its principal modern application is to the uncial manuscripts of the New Testament, as the *codices Alexandrinus*, *Vaticanus*, *Ephraemi*, *Bezæ* or *Cantabrigiensis*, *Claromontanus*, &c., 41 in all, which are also designated by the Roman letters, as codices A, B, C, D, or by combinations, as F^a, W^b, or by the Greek letters, as Δ, Θ.—A *codex rescriptus* (Lat., a rewritten codex), now usually termed a palimpsest, is an ancient parchment on which the original writing has been defaced, and a different composition copied.

CODICIL (Lat. *codicillus*, diminutive of *codex*), an addition or supplement to a will, requiring the same formalities of execution and the same testamentary capacity. The distinction between the two formerly was, that by a will an executor was appointed, and by a codicil not; but now an executor may be appointed by either or by neither, and the codicil is employed to meet changes of purpose on the part of the testator, and to provide for new circumstances. A will and codicil are to be construed together, and the latter, as the more recent expression of the testator's purpose, will modify and control the other wherever they are not in harmony; but in other particulars the will is to stand. There may be several codicils to a will, all of which must be probated with it; but any one may be rejected for want of the legal requisites, and the others will remain and have effect as if that had never been made.

COD-LIVER OIL, the oil drained or expressed from the livers of the cod, and also of the pollock, hake, and haddock, largely used in medicine. Other fish oils are sometimes fraudulently substituted; the adulteration is to be detected by the taste and smell, the ab-

sence of the violet or red color reaction with sulphuric acid characteristic of the biliary acids, and by the specific gravity, that of shark liver oil, which also gives the violet reaction with sulphuric acid, being 0·866, which is less than that of cod liver oil. The latter varies in color from a light yellow to a dark brown, and in taste and smell from a slight and hardly disagreeable, though characteristic flavor and odor, to a nauseous taste and a repulsive odor. These varieties depend upon the condition of the livers at the time of the extraction of the oil, and upon its subsequent treatment. That which is derived from fresh livers is the lightest in color and has the least smell. The darker and more disagreeable varieties are procured from livers which have undergone more or less putrefaction. The chemical composition of cod liver oil is not yet satisfactorily made out. It contains a dark brown, odorless and tasteless substance called gaduine; oleine and margarine; butyric and acetic acids; biliary principles; iodine, chlorine, and bromine in exceedingly small quantities; phosphoric and sulphuric acids; phosphorus, lime, magnesia, soda, and iron. The volatile alkaloid propylamine, which imparts a peculiar odor to herring pickle, and which is probably identical with secalia obtained from ergot, may be derived from cod-liver oil by distillation with ammonia.—Cod-liver oil is employed with advantage in diseases which are characterized by impaired nutrition. It is regarded as one of the most useful remedies known in medicine. In pulmonary consumption, although not a specific, it contributes, when well borne, to the nourishment of the patient, relieves many unpleasant symptoms, and often prolongs life. Its action is probably that of an easily assimilated fat, furnishing in itself an important element of food, and assisting in the assimilation of other nutritive principles. Considerable importance has been attributed to the therapeutic action of the minute quantity of iodine and other inorganic constituents which cod-liver oil contains, and with better reason to the biliary acids and other peculiar substances that enter into its composition. The biliary principles may probably be found in larger proportion in the "extract of cod liver," prepared by evaporating the watery liquid which escapes from the liver when the oil is extracted, than in other preparations of oil. This preparation has been declared, chiefly however by those interested in its sale, to possess a degree of remedial efficacy that has not yet been proved. The chief objection to the administration of cod-liver oil, and one that is sometimes insuperable, is its taste. This may be more or less completely disguised by aromatics, bitters, oil of bitter almonds, or the froth of porter. It may be partially saponified by an alkali, or made into an emulsion. One of the simplest and easiest methods of avoiding its disagreeable taste is to masticate a few cloves and swallow the oil before their pungent impression upon the mouth has departed, when the taste of the oil will not be perceived. Cod-liver oil is chiefly used as a remedy in pulmonary consumption, but its efficacy is not confined to this affection. It may be advantageously prescribed in many forms of impaired nutrition, and especially in the protean derangements resulting from impaired nervous power. It should not be administered when it reduces the appetite or disturbs digestion. It is usually borne best if it is taken about an hour after a meal. Its good effects are most evident when it has been taken for several months consecutively. The dose is from a teaspoonful to a tablespoonful three times a day. Four or five grains of pancreatine added to each tablespoonful will make the oil set better.

CODOGNO, a town of Lombardy, Italy, in the province and 32 m. S. E. of Milan, between the Po and the Adda; pop. about 9,000. It has broad streets, several colleges and schools, good private buildings, some handsome churches, a hospital, and a theatre. It is noted for its silk manufactures, and for being the principal mart in Italy for Parmesan cheese. The Austrians were defeated here in 1746 by the Spaniards, and in 1796 by the French.

CODRINGTON. I. Sir **Edward,** an English admiral, born in 1770, died in London, April 28, 1851. He became a lieutenant in the navy in 1793, and served on board Lord Howe's flag ship at the victory over the French, June 1, 1794. He was soon after made a post captain, and at the battle of Trafalgar commanded the Orion, 74. Subsequently he took part in the bombardment of Flushing, in Strachan's expedition to the Scheldt, and in the defence of Cadiz; and commanded a squadron against the French on the coast of Catalonia. In 1814 he was promoted to the rank of rear admiral, and employed on the American station. On July 10, 1821, he became vice admiral, and in 1826 was placed in command of the fleet in the Mediterranean. In this capacity he had the chief command of the combined British, Russian, and French fleets at the battle of Navarino, Oct. 20, 1827, and, although that action was spoken of by the British government as an "untoward event," he was rewarded both by England and Russia. He represented the borough of Devonport in parliament from 1832 to 1839. A memoir of his life has been edited by his daughter, Lady Bourchier (2 vols., London, 1873). **II.** Sir **William John,** an English general, son of the preceding, born in 1800. He entered the Coldstream guards in 1821, and rose through the successive grades to the rank of major general, which he attained in 1854. His promotion having left him unattached, he joined the army in the East as an amateur, but the commander-in-chief, Lord Raglan, soon gave him the first brigade of the light division, with which he played a distinguished part at the battles of the Alma and Inkerman; and when Gen. Sir George

Brown was wounded, he succeeded to the command of the light division. He directed the attack on the redan, but his conduct on that occasion subjected him to depreciating comments from some quarters. On the resignation of Gen. Simpson he was appointed to the chief command, and in that capacity brought the troops home. He was elected member of parliament for Greenwich in April, 1857, and sat till 1859, when he was appointed governor of Gibraltar. The colonelcy of the 23d fusiliers was bestowed upon him in 1860, and he was promoted to the rank of general in July, 1863.

CODRUS, the last king of Athens, son of Melanthus, reigned, according to tradition, about 1068 B. C. The legend relates that when Attica was invaded by the Dorian Heraclidæ from Peloponnesus, the oracle declared that those would be victorious whose king should be slain. Codrus thereupon determined to sacrifice himself, entered the camp of the enemy in disguise, provoked a quarrel with the common soldiers, and was slain in the fray. The Dorians, having learned the death of the Attic king, abstained from hostilities and returned home; and the Athenians, thinking no one worthy to succeed Codrus, abolished the kingly dignity, and instituted in its stead the office of archon. Medon, son of Codrus, was the first archon.

COEHORN, or **Cohorn, Menno van,** baron, a Dutch general and engineer, born in Friesland in 1641 (according to some in 1632), died at the Hague, March 17, 1704. A captain at the age of 16, he distinguished himself at the siege of Maestricht, and at the battles of Senef, Cassel, St. Denis, and Fleurus. During the intervals of active duty he devoted much attention to the subject of fortification, with the view of equalizing the chances between besiegers and besieged, the new system of his contemporary Vauban having given great advantages to the latter. While a young man he gained a name as an engineer, and by the time he had reached middle life was recognized as the best officer of that arm in the Dutch service. The prince of Orange promised him a colonelcy, but as he was remiss in fulfilling the pledge, Coehorn retired in disgust, with the intention of offering his services to the French. His wife and eight children, however, were arrested by order of the prince as hostages for his return, which quickly brought him back, when he received the promised rank, and was afterward appointed successively general of artillery, director general of fortifications, and governor of Flanders. His whole life was spent in connection with the defences of the Low Countries. At the siege of Grave, in 1674, he invented and for the first time made use of the small mortars called cohorns, for throwing grenades, and in the succeeding year elicited the applause of Vauban by successfully crossing the Maas, and carrying a bastion which was considered as protected by the river. After the peace of Nimeguen (1678) he was employed in strengthening various already strong places. Nimeguen, Breda, Bergen-op-Zoom, and other fortresses, attest the value of his system. The last named place he considered his masterpiece, but it was taken after a long siege in 1747 by Marshal de Löwendal. During the campaigns from 1683 to 1691 he was in active service. The siege of Namur in 1692 gave him an opportunity to test his system against that of Vauban, for these two great engineers were there opposed to each other, Coehorn in defending a work which he had constructed to protect the citadel, and Vauban in attempting to reduce it. Coehorn made an obstinate defence, but, being dangerously wounded, was compelled to surrender to his rival. He was afterward engaged at the attacks on Trarbach, Limburg, and Liége, and in 1695 aided in retaking Namur. In the war of the Spanish succession he besieged successively Venloo, Stephensworth, Roeremond, and Liége; and in 1703 he took Bonn, on the Rhine, after three days' cannonade of heavy artillery aided by a fire of grenades from 500 cohorns. Next he passed into Flanders, where he gained several successes over the French, and subsequently directed the siege of Huy. This was his last service, for he died soon afterward of apoplexy, while waiting a conference with the duke of Marlborough on the plan of a new campaign. Coehorn's greatest work, *Nieuwe Vestingbouw* (fol., Leeuwarden, 1685), was translated into several foreign languages. His plans are mostly adapted to the Dutch fortresses, or to those which are similarly situated on ground but a few feet above water level. Wherever it was practicable, he encircled his works with two ditches; the outermost full of water, the inner dry, and usually of the width of about 125 ft., serving as a *place d'armes* for the besieged, and in some cases for detachments of cavalry. The theory of his system, both of attack and defence, was the superiority of a combined mass over isolated fire. Professionally, Coehorn was accused of wasteful expenditure of life, in which respect he contrasted unfavorably with Vauban, who was sparing of men. He refused inducements offered by several foreign governments. Charles II. of England knighted him. He was buried at Wijkel, near Sneek, in Friesland, and a monument was dedicated there to his memory. His biography was written by his son Theodorus (new ed., by Sypestion, 1860). For his system of fortifications, see Zastrow, *Geschichte der Befestigung* (3d ed., 1854).

COELLO, Claudio, a painter, born in Madrid, of Portuguese parents, in 1621, died there in 1693. He excelled both in color and design, and was made painter to Charles II., for whom he executed many works in the Escorial. His chief work is the altarpiece in the sacristy, representing the ceremony of the collocation of the host. His works are numerous in Madrid, Salamanca, and Saragossa.

CŒLUS. See URANUS.

CŒUR, Jacques, a French merchant and royal treasurer, born at Bourges near the end of the 14th century, died in the island of Scio, Nov. 25, 1456. He was at first one of the masters of the mint at Bourges, and afterward engaged in commerce on a vast scale, visiting Egypt and Syria, establishing depots throughout the East, and covering the Mediterranean with his ships. Thus he acquired a great fortune and attracted the attention of Charles VII., who in 1435 appointed him head of the French mint, and afterward treasurer. His excellent management of affairs caused the king to ennoble him, and to intrust him with high functions in the French provinces, and with diplomatic missions in Italy. Cœur contributed 200,000 crowns to help the king in rescuing Normandy from the English. After the successful end of the war, his influence became so great as to give offence to envious persons, who after the death of the king's mistress, Agnes Sorel, charged him with having poisoned her, and caused him to be arrested (1451), and his vast property to be confiscated. Although the charge was proved to be groundless, he was detained in prison till 1455, when he effected his escape. Repairing to Rome, he was kindly received by Pope Nicholas V., and was enabled to gather the broken remains of his fortune. Pope Calixtus III. selected him in 1456 as captain general of a fleet against the Turks. On this expedition Cœur was overtaken by illness, died, and was buried in the church of the Franciscans in Scio. He had vainly implored the clemency of Charles VII. in favor of his family. Under Louis XI. his memory was exculpated from all charges, and a part of his property was afterward restored to his descendants.—See *Jacques Cœur et Charles VII., ou la France au XV^e^ siècle* (2 vols., Paris, 1853).

CŒURS D'ALÊNE (Awl-hearts), an Indian tribe in Idaho and Washington territories, of the Selish family, although their dialect differs greatly from others of the language. They call themselves Skizoomish, or Skitzuish, but are known generally by the above name, given them by the French voyageurs. They were poor, distrustful, and cruel, and lived on fish, roots, and small game, not visiting the bison grounds. Although estimated in 1822 at 2,000, they numbered but 300 in 1870. In 1841 Father De Smet visited them. In 1842 a Catholic mission was begun, which was removed in 1846 to a place 30 m. from Cœur d'Alêne lake (the source of Spokane river), where they had a church, a mill, and dwellings. The tribe became Christians, but viewed with jealousy the entrance of whites into their country; and in 1858 their chief, Vincent, with 100 warriors, joined Kamiakin, the Yakama chief, in his attack on Col. Steptoe. They were defeated by Col. Wright in the battles of Four Lakes and Spokane plains, and have since been peaceful. A part of the tribe in Idaho had a reservation set apart for them by an executive order of June 14, 1867; and by order of July 2, 1872, those in Paradise valley were removed against their protest to a reservation between the Okinakane and Columbia rivers and British America.

COFFEE (Turkish, *kahve*), the seeds of the plant *coffea Arabica*, of the order *cinchonaceæ;* also the beverage prepared by infusion or decoction of them in boiling water. In southern Abyssinia the plant grows wild in great profusion, and there it has been in use from very remote times. Its name is therefore generally derived from Kaffa, the name of a district S. of Abyssinia. It also grows wild in western Africa. The coffee-producing belt of the world lies between the isothermal lines of lat. 25° N. and 30° S. The plant grows at an altitude as high as 6,000 ft. above the sea; but it does not flourish where the temperature is below 55°. It thrives in warm situations upon the slopes of hills and in soil not retentive of rain. The cultivation of coffee is widely diffused throughout the tropics, the

The Coffee Plant.

principal countries being Brazil, Java, Ceylon, Sumatra, the isle of Réunion, the western coast of India, Arabia, Abyssinia, the West Indies, Central America, Venezuela, Guiana, Peru, Bolivia, and some of the Pacific islands. The plant attains the height of 8 to 20, and sometimes 30 ft. The trunk is covered with a grayish bark, and its white flowers grow in thick clusters around the branches. It is usually kept down by pruning to about 5 ft. in height, to increase its productiveness and for convenience in gathering the fruit. The slender and pliable branches then spread out and bend down like those of an apple tree. The plants are raised from the seed in nurseries, and when a year old are transplanted and set out in rows. In three years they begin to yield fruit, but are not in full bearing till the fifth year; they continue to yield for 20 years or longer. The leaves, of oblong-ovate and pointed form, grow in pairs, one opposite the other. They are four or five inches long, smooth and shining, and of dark green color. The plant being an

evergreen, the foliage is always fresh; and though at certain seasons the blossoms suddenly appear scattered among the dark leaves like flakes of snow, they are hardly ever entirely absent. They continue to put forth while the fruit of former blossoms is coming to maturity, and so the ripe coffee may be gathered at almost every season; but the real harvests are usually two, and sometimes three, in the course of the year. The fruit when ripe becomes red and finally dark purple. It resembles a cherry, and the fleshy portion which surrounds the seeds is very sweet and palatable. Each berry contains two seeds; their flat sides are opposed to each other in the centre of the pulp, and are separated by a thin layer of this and by the tough membrane which closely envelopes both. Sometimes one seed is abortive, and the other becomes round. This is the case with the Wynaad coffee from India, and the so-called "male berry" coffee. As the fruit dries, the pulp forms a sort of shell or pod, which is removed by a process of curing in order to prepare the seed for market. In the West Indies the fruit is picked by hand at intervals during the seasons of harvest; but in Arabia, where no rains prevail which would beat it from the trees, it is allowed to remain till ready to fall, and is then shaken off upon cloths spread upon the ground. Its perfect ripeness may be one reason of its superior quality. It is next dried in the shade, and the pulp is afterward removed by hand. In the East and West Indies and South America the curing is usually performed by exposing a layer of the fruit several inches in thickness to the heat of the sun, so that fermentation takes place. When the moisture has disappeared, the dried fruit is passed between wooden rollers, and sometimes pounded in wooden mortars, and the pulp is then washed away. The tough membrane is separated after the seeds are dry by a similar process with a heavy pair of rollers. The chaff is next removed by winnowing.—From Ethiopia the use of coffee is said to have been introduced into Persia as early as A. D. 875, and into Arabia from the latter country or from Africa about the 15th century. The earliest written accounts of the use of coffee are by Arabian writers of this period; and it appears that in the city of Aden it became in the latter half of this century a very popular drink, first with lawyers, studious persons, and those whose occupations required wakefulness at night, and soon after with all classes. Its use gradually extended to other cities, and to those on the eastern shores of the Mediterranean. It is said to have been publicly sold in Constantinople in 1554, and to have found its way thence to Venice in 1615. Rauwolf, a German (in 1582) is said to be the first European who makes mention of it. The plant is described in the works *De Plantis Ægypti* and *De Medicina Ægyptiorum* of Prospero Alpini, 1591 and 1592. Burton in his "Anatomy of Melancholy" (1621) is supposed to be the first English writer who notices it. "The Turks," he says, "have a drink called coffee (for they use no wine), so named of a berry as black as soot and as bitter, which they sip up as warm as they can suffer, because they find by experience that that kind of drink so used helpeth digestion and procureth alacrity." A Greek servant of a Turkey merchant opened the first coffee house in London in 1652, the first in England having been opened a year before at Oxford by a Jew, Jacob. At the close of the century the annual consumption of coffee in the kingdom amounted to about 100 tons. Its culture was introduced into Java from Arabia by the Dutch between 1680 and 1690, and it was thence extended throughout the East India islands. In 1715 Louis XIV. received from the magistrates of Amsterdam a fine coffee tree, then bearing both green and ripe fruit. This, according to Du Tour, was the stock of all the West India coffee. The Dutch introduced its cultivation into Surinam in 1718. (See H. Welter, *Essai sur l'histoire du café*, Paris, 1868).—The raw coffee beans are tough and horny, difficult to reduce to powder, and consequently require a preparatory roasting, that water may take up their soluble ingredients. Even after this the hardness of the fragments is such that the genuine particles may by this quality be distinguished from those of other substances used as adulterants. The average composition of raw coffee, as determined by M. Payen, is in 100 parts:

Cellulose	34·00
Water	12·00
Fat	10 to 13·00
Glucose, dextrine, and organic acid	15·50
Legumine and caseine	10·00
Other nitrogenous substances	3·00
Caffeine (free)	0·80
Caffetannate of caffeine and potassium	3·5 to 5·00
Viscid essential oil (insoluble in water)	0·001
Aromatic oils, some lighter, others heavier than water	0·002
Ash	6·70

Some authorities state that it contains from 6 to 8 per cent. of cane sugar; in the roasting this must be nearly or quite all converted into caramel. The most important principles are the caffeic acid, resembling in its astringent character, and also in containing much gluten, the tannin of tea; the alkaloid, caffeine, which is identical with the theine of tea; and the fragrant volatile oil, called caffeone. This oil is distinguished by the microscope in minute drops in the cells or between the outer membrane and the body of the seed, and may be taken up by distillation with water. Roasting disperses it through the solid substance, and in part or wholly expels it, if the process is pushed too far. The caffeic acid, especially, is modified by roasting, and is supposed by chemists to afford the greater portion of the flavor and peculiar properties of the coffee. The proportion of caffeine is only about one half that of theine in an equal weight of tea. (See CAFFEINE.) Coffee when roasted loses its hygroscopic water, which should first be allowed to

escape at a moderate heat from an open vessel. The process may then be continued at a higher temperature in a vessel closed to prevent the escape of the aroma, and constantly agitated to avoid charring the grains and expelling the oil, by which its bitter quality is made to predominate and the aromatic is lost; a slight excess of heat injures the quality of the coffee. The process should be stopped when the beans are of a chestnut brown; they have then lost about 20 per cent. in weight and gained 50 per cent. in bulk. When removed from the fire, the vessel should be kept closed until cool, that the aromatic vapor may be reabsorbed as much as possible. After roasting, it deteriorates by exposure, and should therefore be soon used, unless kept in tight vessels. It may be injured by absorbing the odor of other substances. Even the raw coffee is liable to be damaged from this cause, and it is found objectionable to ship it in vessels that have been previously freighted with sugar; a few bags of pepper have spoiled a whole cargo of coffee. Freshly roasted and ground coffee tied up in linen has been found to ignite spontaneously. After roasting, the coffee is ground to powder. Boiling, if continued, will cause a loss of the aroma, and increase the bitterness; hence an infusion obtained by steeping is preferable to a decoction, but the water should remain in contact with the coffee long enough to extract the greater portion of its agreeable qualities, which is not the case in the use of the percolating apparatus introduced by Count Rumford, and afterward variously modified. In Arabia the berry is coarsely broken in a mortar, boiled smartly, and strained before drinking. In Asia coffee is used in a thick decoction. In Sumatra the natives make use of the leaf of the plant instead of the seed, ascribing to it more of the bitter and nutritious property. It may also be cultivated for the leaves where the production of seed would fail from unsuitableness of climate or soil. The leaves are moderately roasted and then rubbed to powder in the hands, and this powder is used like tea. The infusion is said to resemble in taste coffee, as usually prepared, and tea combined.—It is a remarkable fact that the same peculiar principle should exist in three or more vegetable productions, which, though not at all resembling each other in other respects, have been selected as beverages by almost all nations, some adopting one of them and others another. This fact, pointed out by Liebig, as also that this principle furnishes the elements of the bile, is suggestive of a peculiar adaptation of it to the needs of the human system. This principle, called theine in tea and caffeine in coffee, is theobromine in cocoa, and the same is recognized in the *guarana officinalis* and the *ilex Paraguensis*, which have long served the aborigines of South America the purposes of tea. Coffee and tea are both used in temperate regions; but in the colder climes tea appears to be generally preferred, and is frequently exclusively employed. The northern limit of the coffee-consuming portion of the world is about 60°. —The best coffee of commerce is the Mocha, and next to this is the Java. The seeds of the former are small and of a dark yellow color; those of Java and the East Indies are larger and of a paler yellow; while those of the West Indies and Brazil have a bluish or greenish gray tint. The Mocha coffee is grown in the province of Yemen, in Arabia; but much of the coffee sold under that name is produced in the East Indies and sent to Mocha, where it is reshipped, while no inconsiderable portion of it comes from Africa and Brazil. Java coffee is distinguished into pale yellow, the newest and cheapest, and brown, which is the oldest and most esteemed. These varieties depend on the curing and the age of the coffee. The principal markets for Java coffee are Holland and the United States. The greatest coffee-producing country is Brazil, more than half the coffee consumed in the world being produced there. It is the great commercial staple of the empire, and its principal market is the United States. Besides the provinces adjacent to Rio de Janeiro, the coffee plant flourishes in the shade of the Amazon forests, and, with moderate care, yields two annual crops; and the Ceará coffee, much esteemed, grows on the mountain slopes, at an elevation of from 2,000 to 3,000 feet above the sea. In the province of Pará the coffee plant is seen growing on almost every roadside, thicket, or waste. The coffee of Brazil has little reputation, and is even underrated. This is attributed by Prof. Agassiz to the fact that "a great deal of the best produce of Brazilian plantations is sold under the name of Java, or as the coffee of Martinique or Bourbon, while the so-called Mocha coffee is often nothing but the small round beans of the Brazilian plant found at the summits of the branches and very carefully selected." The total exports from Rio de Janeiro and Santos are stated at 401,127,200 lbs. in 1869–'70, 468,063,200 lbs. in 1870–'71, and 327,226,080 lbs. in 1871–'2. The amount of coffee received into the United States from Brazil has been as follows for a series of years:

Year	Pounds.	Value.	Year.	Pounds.	Value.
1860	156,583,272	$16,984,135	1869	205,473,604	$19,255,967
1865	80,529,223	7,798,370	1870	183,413,456	18,322,580
1866	166,929,289	13,707,820	1871	257,472,708	24,339,488
1867	147,136,981	15,386,844	1872	194,218,511	23,970,822
1868	199,326,171	.....			

In 1868, 15,822,501 lbs. of coffee from Brazil were imported into Great Britain; in 1869, 22,267,953; in 1870, 14,057,893; and in 1871, 23,066,344. Next to Brazil in extent of production is Java. The amount exported from Java and Sumatra to Europe in 1860 is stated at 122,790,923 lbs.; in 1869, 121,655,798; and in 1870, 156,010,912. Almost the entire production of Java is shipped to Holland. The amount thus received into Holland in 1867 was

157,036,316 lbs.; in 1868, 145,935,724; in 1869, 110,456,626; and for the 11 months ending Nov. 30, 1870, 142,039,928. Great Britain is the principal market for the coffee produced in Ceylon, which ranks third as a coffee-producing country. In 1860, the amount imported from Ceylon into Great Britain was 63,244,900 lbs., valued at £1,599,293; in 1868, 101,929,153 lbs., valued at £2,986,479; in 1869, 95,103,970 lbs., valued at $2,867,724; in 1870, 97,964,922 lbs., valued at £2,790,898; and in 1871, 90,680,570 lbs., valued at £2,623,263.—The most extensive coffee-consuming countries are the United States, Great Britain, France, and Germany. In the United States, according to the report of the chief of the bureau of commerce and navigation, the consumption for several years, ending June 30, has been as follows:

Year	Pounds.	Value.	Year.	Pounds.	Value.
1867	159,644,977	$17,805,087	1870	253,571,664	$25,630,715
1868	212,379,267	22,315,316	1871	120,932,617	29,428,894
1869	230,814,376	22,779,574	1872	239,735,829	26,140,339

The total amount of coffee imported into the United States for a series of years, with the value, is as follows:

Year.	Pounds.	Value.	Year.	Pounds.	Value.
1860	200,998,751	$21,768,939	1867	187,236,580	$20,696,259
1862	40,474,917	4,767,117	1868	248,983,900	25,288,451
1863	80,461,614	10,395,360	1869	254,160,993	24,531,743
1864	131,622,782	16,621,586	1870	235,256,574	24,234,879
1865	104,316,581	10,966,541	1871	317,992,048	30,992,869
1866	174,280,674	19,739,381	1872	298,805,946	37,942,225

The chief countries whence coffee was imported into the United States in 1872 were:

COUNTRIES.	Pounds.	Value.
Brazil	194,218,511	$23,970,822
British East Indies	4,141,547	516,074
British West Indies	2,841,261	383,924
Central American States	9,598,954	1,182,053
Dutch East Indies	14,722,299	3,300,417
England	5,979,350	948,312
France	7,695,324	1,175,003
Germany	3,093,439	476,572
Hayti	3,874,781	468,864
Holland	843,243	154,180
Mexico	1,878,301	248,022
Porto Rico	2,021,891	319,558
United States of Colombia	4,142,067	498,696
Venezuela	28,183,607	3,604,496

The total amount of coffee imported into Great Britain for the year ending Dec. 31, 1871, was:

FROM	Pounds.	Computed real value.
Brazil	23,066,344	£564,611
British India	33,413,058	960,923
Central America	19,544,519	568,262
Ceylon	90,680,570	2,623,263
Other countries	25,288,289	677,452
Total	191,992,780	£5,394,511

The imports and the quantities retained for home consumption have been:

YEARS.	Imports, lbs.	Value.	Home Consumption, lbs.
1865	137,997,451	£4,600,887	30,505,972
1866	127,044,816	4,089,329	30,630,236
1867	137,729,716	4,362,760	31,282,023
1868	173,902,477	4,858,107	30,356,818
1869	173,416,332	4,927,805	28,839,100
1870	179,901,864	4,942,769	30,230,572
1871	191,992,780	5,394,511	30,602,023
1872	166,269,052	5,257,403	31,173,555

The amount of coffee imported into France for home consumption was 104,268,255 lbs. in 1867, 115,380,744 lbs. in 1868, 110,996,852 lbs. in 1869, and for the six months ending June 30, 1870, 59,913,571 lbs. From 1789 to 1830 a duty of 2½ cents per pound was imposed upon coffee imported into the United States. In the latter year this duty was removed, but again imposed in 1861. It varied from 3 to 5 cents per pound until July 1, 1872, when the importation of coffee was again made free.—An infusion of roasted coffee contains three constituents which differ somewhat in their action. These are tannic acid, caffeine, and empyreumatic products of the albumen and legumine of the raw berry. Only a small portion of the caffeine is destroyed in the roasting, and that is mostly converted into methylamine. (See CAFFEINE.) Coffee increases the frequency of the pulse and activity of the mind, which is often so prolonged as to prevent sleep. Large doses produce palpitation of the heart, and habitual coffee drinkers are liable to have the digestion considerably impaired. In the absence of belladonna, it may be used as an antidote in cases of poisoning by opium, a strong infusion of the burnt berry being used and given in doses according to the symptoms. It is sometimes given to relieve vomiting, particularly of a nervous character. Roasted coffee neutralizes noxious odors, and is antiseptic in a mild degree. It is best applied by first drying and crushing the raw beans, and then roasting the powder at a moderate heat to a dark brown color, when it may be sprinkled about or simply exposed on a plate where the effluvium exists. It is often adulterated (see ADULTERATION, and CHICORY), and this may be suspected when water is quickly colored by it, and the presence of chiccory or burnt sugar inferred. One of the readiest means of detecting foreign vegetable or animal matter is by using the microscope. Venetian red or native sesquioxide of iron may be detected in the ashes either by inspection or the application of chemical reagents.

COFFEE. I. A S. E. county of Georgia, bounded N. by the Ocmulgee river, S. W. by the Allapaha, and intersected by the Satilla and its branches; area, 1,000 sq. m.; pop. in 1870, 3,192, of whom 678 were colored. The surface is level and sandy. The Macon and Brunswick railroad touches the N. E. corner, and the Brunswick and Albany railroad passes through the S. part. The chief productions in 1870 were 49,022 bushels of Indian corn, 19,-

949 of oats, 45,996 of sweet potatoes, 15,845 lbs. of rice, 42,366 of wool, 261 bales of cotton, and 12,231 gallons of molasses. There were 403 horses, 3,925 milch cows, 10,384 other cattle, 16,036 sheep, and 12,779 swine. Capital, Douglas. **II.** A S. E. county of Alabama, watered by Pea river; pop. in 1870, 6,171, of whom 1,020 were colored. The former area was 900 sq. m., but portions have been taken to form Crenshaw and Geneva counties. The surface is somewhat hilly, and the soil generally poor. Pine timber grows in great abundance. The chief productions in 1870 were 121,352 bushels of Indian corn, 28,254 of sweet potatoes, 2,004 bales of cotton, 13,098 gallons of molasses, and 8,975 lbs. of rice. There were 617 horses, 2,142 milch cows, 5,346 other cattle, 4,059 sheep, and 9,433 swine. Capital, Elba. **III.** A central county of Tennessee; area, 320 sq. m.; pop. in 1870, 10,237, of whom 1,501 were colored. It has an elevated and hilly surface, and a fertile soil. It is traversed by the McMinnville and Manchester railroad. The principal productions in 1870 were 43,075 bushels of wheat, 10,226 of rye, 309,503 of Indian corn, 25,462 of oats, and 30 bales of cotton. There were 2,506 horses, 1,881 milch cows, 2,979 other cattle, 8,107 sheep, and 17,226 swine; 3 flour mills, 5 saw mills, 1 paper mill, 1 distillery, and 2 wool-carding and cloth-dressing establishments. Capital, Manchester.

COFFEY, a S. E. county of Kansas, intersected by the Neosho river; area, 576 sq. m.; pop. in 1870, 6,201. The Missouri, Kansas, and Texas railroad crosses it. The chief productions in 1870 were 47,745 bushels of wheat, 268,218 of Indian corn, 90,190 of oats, 26,879 of potatoes, 14,275 tons of hay, 140,602 lbs. of butter, and 36,702 of wool. There were 2,762 horses, 3,459 milch cows, 6,247 other cattle, 11,917 sheep, and 2,855 swine; 5 manufactories of carriages and wagons, 3 of saddlery and harness, 1 of woollen goods, 2 flour mills, and 7 saw mills. Capital, Burlington.

COFFIN, Sir **Isaac,** an English admiral, born in Boston, Mass., May 16, 1759, died at Cheltenham, Eng., July 23, 1839. He was educated at the public schools in Boston, and having entered the British navy as midshipman in 1773, under the patronage of Admiral Montagu, served in various ships on the American station, being finally attached to the Romney, flag ship of his patron, off Newfoundland. In 1778 he was appointed lieutenant, and in 1781 commander. On March 16, 1781, he acted as signal lieutenant to Admiral Arbuthnot in the action off Cape Henry, and in 1782 was present as a volunteer under Admiral Hood in the engagement between Rodney and De Grasse. In 1788, irritated at having been deprived of his commission for an informality then common in the service, he went to Brabant and gave his aid to the patriots. The sentence against him was soon reversed, and he reëntered the British navy with his former rank. In attempting to save the life of a sailor who fell overboard he received an injury which incapacitated him from active duty, and was placed in charge of the depot at Leith; thence was sent commissioner to Corsica; thence to Elba; subsequently to Lisbon as head of the naval establishment there; and in 1798, when Minorca fell into the hands of the English, he was appointed superintendent of the arsenal at Port Mahon. In 1804 he was advanced to the rank of rear admiral of the blue; next year was made a baronet; in 1808 vice admiral, and in 1814 admiral. In 1818 he was elected member of parliament for Ilchester, and retained his seat till the dissolution in 1826. His speeches were chiefly on naval affairs, and distinguished for blunt, sailor-like honesty, with a strong vein of facetiousness. He always retained a warm affection for his native city, and visited it many times. In 1826 he founded a school in Nantucket, still called by his name.

COFFIN, James Henry, an American mathematician, born in Northampton, Mass., Sept. 6, 1806, died in Easton, Pa., Feb. 6, 1873. He graduated at Amherst college in 1838, was afterward professor in Williams college till 1843, and superintended the establishment of Greylock observatory, on the mountain of that name in western Massachusetts, with the first combined self-registering aërometer and barometer. He was professor of mathematics and astronomy in Lafayette college, Easton, Pa., from 1846 till his death. He published "Solar and Lunar Eclipses," "A Discussion on the Meteoric Fire Ball," and "Winds of the Northern Hemisphere" (issued by the Smithsonian institution, 1851; enlarged and revised, 1873).

COGALNICEANO, or **Cogalnitchanu, Michael,** a Roumanian historian and statesman, born about 1806. He filled the newly established chair of history at Jassy, founded scientific, literary, and political journals, promoted the emancipation of the gypsies, and became prominent, under Prince Alexander Cuza's administration, in the legislature and as minister for Moldavia. After the union of Wallachia and Moldavia in December, 1861, he became prime minister, and was the chief promoter of the new electoral law of May 14, 1864, and of the arbitrary constitution; but he was obliged to retire shortly before the forced abdication of Cuza, Feb. 23, 1866. He was chiefly instrumental in the foundation of the university at Jassy. He has since been reëlected to the chamber, and under Prince Charles was minister of the interior from November, 1868, to Jan. 24, 1870. He has published *Histoire de la Valachie et de la Moldavie* (Berlin, 1837); *Archiva romanesca* (1841); and *Letopisitz*, a collection of Roumanian historical documents (3 vols., Jassy, 1845–'52).

COGHETTI, Francesco, an Italian painter, born in Bergamo, Oct. 4, 1804. He studied in that city under Diotti, and in Rome under Camuccini, and executed various fine altarpieces for churches in Bergamo, which led to his being employed upon paintings for the cathedral and other buildings. For the villa Torlonia at

Rome he painted the exploits of Alexander the Great, and he also embellished Prince Torlonia's villa at Castel-Gandolfo and his palace at Rome. In his frescoes in the basilica of Savona and many of his oil paintings, including the "Condemnation of St. Stephen," which procured for him an order of knighthood, he has closely imitated the old masters; and he stands at the head of a new school, which strives to revive the classical style of painting.

COGNAC, a town of France, in the department of Charente, 22 m. W. of Angoulême; pop. in 1866, 9,412. It is situated upon an eminence on the left bank of the Charente, and is well built. It enjoys a great celebrity on account of the brandy to which it has given its name. All the brandy of Charente and Charente-Inférieure is sold as Cognac, but the genuine article is made in the immediate vicinity of the town; the best second qualities are produced at Blanzac, Jarnac, Rouillac, Aigre, and Ruffec. The whole trade in brandy amounts to about 80,000,000 francs annually. The town also has a trade in cattle, sheep, grain, spirits, and truffles. An ancient castle, in which Francis I. was born, is now used for a brandy warehouse.

COGNATES, in Scotch law, collateral kindred on the mother's side, as agnates are collateral kindred on the father's side. The terms were employed in the Roman civil law somewhat differently, agnates being persons related through males only, while cognates might trace relationship through one or more female links. Thus, a brother's son was the uncle's agnate, but a sister's son was his cognate. Generally speaking, however, cognates were all who were descended from a common ancestor through a legal marriage, and the term included agnates also.

COGNIARD, Théodore, a French playwright, born April 30, 1806, died in Paris, May 25, 1872. With his surviving brother, HIPPOLYTE (born Nov. 20, 1807), he wrote hundreds of vaudevilles and fairy plays, many of which had a great run, especially *La biche aux bois.* He brought into vogue the opera bouffe. Offenbach's *Belle-Hélène, Barbe-bleue, Grande Duchesse,* and *Périchole* were first performed under his sole direction at the Variétés theatre, his brother Hippolyte having retired in 1869.

COGNOVIT, a plea in an action at law which admits the cause of action, and expresses or by implication consents that judgment may be entered up for the plaintiff. In a suit to recover damages, the plea may or may not admit the amount due. If it does, and the plaintiff accepts the admission, he may enter up judgment therefor. If it does not, there must be an assessment of damages by court or jury. A warrant of attorney for the execution of a cognovit is sometimes demanded and taken when a debt is created; and by means of it, if payment is not made, judgment may be entered up without delay.

COGSWELL, Joseph Green, LL. D., an American scholar, born at Ipswich, Mass., Sept. 27, 1786, died in Cambridge, Mass., Nov. 26, 1871. After graduating at Harvard college in 1806, he made a voyage to India as supercargo of a vessel, and on his return studied law with Fisher Ames in Dedham. He commenced the practice of law at Belfast, Maine, where he married a daughter of Gov. Gilman of New Hampshire. Her death, and a distaste for the profession, led him to abandon it, and to accept in 1814 a position as tutor at Cambridge. In 1816 he visited Europe, and joined his friends Edward Everett and George Ticknor in studies at Göttingen and other German universities, and in travelling on the continent. He remained abroad about four years, giving special attention to the principles of instruction and education, and already entertained the idea of forming a great public library in the United States. Returning home in 1820, he was appointed professor of mineralogy and geology and librarian in Harvard college. In 1823 he united with George Bancroft in founding the Round Hill school at Northampton, Mass. The plan of this institution had been suggested by observation of the best English and German preparatory schools, and during the five years that Dr. Cogswell was associate head of it, and for about the same period during which he conducted it alone, it attracted students from every part of the country, and exerted an important influence in advancing the standard of American education. After leaving Northampton he had charge of a similar institution in Raleigh, N. C.; but prior to 1839 he settled in New York city, where he became editor of the "New York Review." Being introduced by Fitz-Greene Halleck to John Jacob Astor, he soon became interested and engaged in the great work of his later years. During the closing years of Mr. Astor's life Dr. Cogswell was in daily intercourse with him, living, at his request, in his house as his friend and companion, and arranging the plans and selecting the titles of the books for the great library which it was Mr. Astor's purpose to endow. It was the unnoticed preparatory labors of many years which gave to the Astor library, so soon after the realization of its endowment, its complete and orderly development. Dr. Cogswell was appointed by Mr. Astor one of the trustees of the fund, and designated by the trustees as superintendent of the library before its opening. He made three visits to Europe, examining the principal libraries and book marts of the old world, and collecting the books for the Astor library. The character of the collection demonstrates his appreciation of the value of all branches of knowledge, and his liberal sympathy with every intellectual pursuit. He presented to the Astor library his own bibliographical collection, which was one of the largest and most valuable in this country. He had previously united with Mr. Andrew Ritchie in purchasing in Germany, and presenting to Harvard college, a cabinet of about 5,000 minerals; and

had made to the botanic garden at Cambridge a donation of nearly 4,000 very choice specimens of dried plants of central Europe, which, with the assistance of Mr. Seringe of Bern, he had collected in Switzerland. During Dr. Cogswell's active superintendency of the Astor library, he prepared a valuable alphabetical and analytical catalogue of its contents, which was published in eight large volumes, displaying his extraordinary knowledge of the history, comparative value, and significance of the books he had collected. He continued to perform the active duties of superintendent with singular industry and fidelity, until the pressure of advancing years induced him to retire in 1860. Two years later, having changed his residence to Cambridge, Mass., he resigned the office of trustee. After that time it was his habit to make annual visits of several weeks to his friends in New York. While his physical strength gradually failed, his intellectual powers remained unimpaired to the advanced age of 85, and his sparkling conversation was as interesting as in earlier years. His remains were interred in his native place, where a handsome monument is to be erected by his Round Hill pupils, to testify their affection for their old friend and instructor. He bequeathed one fourth of his moderate fortune to the Manning school of Ipswich, Mass.

COHASSET, a town of Norfolk co., Massachusetts, on the South Shore railroad, 15 m. S. E. of Boston; pop. in 1870, 2,130. It borders N. E. and E. on Massachusetts bay, and is surrounded on all other sides by Plymouth co., being separated on the west by Hingham from the main body of Norfolk co. The peninsula of Nantasket, constituting the main portion of the town of Hull, and forming the S. E. side of Boston harbor, projects N. W. from Cohasset about 5 m., and contains Nantasket beach, 4 m. in length, which is much resorted to for its beauty, fine shell fish, sea fowl, and good bathing. The coast of Cohasset is very rocky, and is noted as the site of Minot's ledge lighthouse. The Conohasset river, which anciently formed the boundary between Plymouth and Massachusetts colonies, flows through a portion of the town. In the S. W. part is a pond of 90 acres, abounding in fresh-water fish. The situation of the town is delightful and romantic, and its ready access from Boston has rendered it a popular summer resort. The inhabitants are chiefly engaged in mackerel fishing and the coasting trade. Cohasset until 1770 formed a part of Hingham, and was called Conohasset, an Indian name signifying a fishing promontory.

COHESION, that kind of attraction by which the particles of bodies are held together, as the molecules of water, of iron, or of stone. It is manifested in a high degree in solids, less in liquids, and but very little or not at all in gases. The molecules of which bodies are composed would seem, from the various phenomena observed in nature and in experiments, to be under the influence of two opposing forces, which under varying conditions alternate with each other in preponderance. One of these forces is molecular attraction, and the other is molecular repulsion. The first is exerted only at inappreciably small distances, but the laws by which it is governed are not known. Repulsion is exerted at greater distances, and is principally controlled by the action of heat, increasing as the heat increases, the abstraction or addition of this agent being usually sufficient to cause matter to assume either the solid, liquid, or gaseous form. Molecular attraction manifests itself in three ways, by cohesion, by adhesion, and by chemical affinity. The degree of cohesion in the same solid depends much upon the arrangement of its particles, as may be observed in the different degrees of hardness between tempered and untempered steel, and the difference in tenacity of metals in ingots or in hammered or rolled plates. The distinction between cohesion and adhesion is not always easily to be established. Adhesion is commonly spoken of as existing between the particles of dissimilar bodies, but it is more accurately defined by calling it that molecular force which holds two distinct bodies together, whether they are of the same substance or not. If two pieces of lead have plane surfaces cut upon them, and these are firmly pressed together, they will continue to be so held by the force of adhesion (independently of atmospheric pressure), and not of cohesion, because that term cannot strictly be applied except when such a union has taken place as to render the structure continuous between the original bodies. To consider, also, cohesion as only capable of existing between particles of the same kind, would lead to conclusions that cannot well be maintained, because in an alloy of two or more metals, even when they are not mingled in the proportions of their atomic weights, it seems proper to consider the particles as being held together by the force of cohesion. As has been intimated, the laws which govern molecular attraction are so imperfectly understood that the relations between cohesion, adhesion, and chemical affinity cannot be stated. The last named force is exerted between atoms or molecules of matter which are not of the same kind; it is manifested with more intensity than is observed in the phenomena of cohesion and adhesion, and is also followed by a more intimate union of the particles, by which the formation of a new body, unlike in its physical properties either of those of which it is composed, is accomplished. Heat exerts a remarkable influence upon these forces, and indicates the differences which exist in their nature. Adhesion does not seem to be so uniformly diminished by its action as cohesion, for the adhesion between substances is often increased thereby, while cohesion is constantly diminished. Chemical affinity is also generally increased with the increase of heat, certainly while union is taking

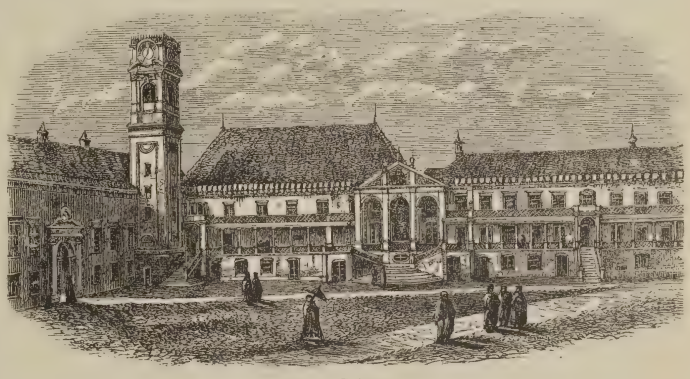
place, whatever may be its effect upon the compound after union; but that heat has the power of diminishing the affinity with which the atoms of a compound are held together is shown by its decomposing action on some of the metallic oxides, as those of silver and mercury. The manifestations of chemical affinity between two uniting bodies are no doubt often heightened by the application of heat, in consequence of its diminishing the cohesion or increasing the repulsion between the molecules of each of such uniting bodies. The conversion of water into steam is an example of the neutralization of the force of cohesion by the application of heat, without any appreciable diminution of the force of chemical affinity. The cohesive force of the atoms or the molecules of bodies depends on their distance from one another, decreasing as the distance increases, and disappearing entirely when that becomes sensible; but the law by which the decrease takes place is not known. It has been questioned, however, whether molecular attraction may not follow the law of attraction of gravitation, varying inversely as the squares of the distance; or, in other words, whether the two are not modifications of the same force. Under this assumption the explanation of the cessation of cohesive attraction at sensible distances is furnished by the obvious fact that any sensible distance is almost infinitely so much greater than the distance between the centres of the adjacent atoms or molecules of a solid or liquid, that the difference in the attractive forces becomes practically infinite. The question as to the amount of cohesive force which exists between the molecules of liquids is attended with difficulty. The fact that water will boil in a vacuum at a low temperature might suggest the inference that there exists no positive cohesive force between its particles; but the formation of spherical drops of water is opposed to such a conclusion. Again, when a liquid boils in the open air it is usually considered that the repulsion between the molecules is sufficient to overcome the pressure of the atmosphere, and therefore it would appear as if there were no cohesive attraction between them; but the irregularity with which ebullition takes place under certain circumstances, as when the air which is usually contained in water has been expelled, would seem to confirm the opinion that in reality there are present both attractive and repulsive forces, which alternate in predominance; the attractive force predominating when the molecules are within certain distances, especially when they are comparatively at rest, and the repulsive force predominating when the distances are deranged by motion, or increased by the intrusion of particles of vapor or air. (See Boiling Point.) Moreover, water may be considerably reduced in temperature below its freezing point without congelation taking place, when a jar given to the vessel, or a pebble or crystal dropped into it, will cause the immediate manifestation of intense cohesive force and the formation of ice. It would therefore appear that the molecules of a liquid may have slight cohesive attraction for each other, even when the temperature is sufficient to cause repulsion between the particles of its vapor; and also that when the freezing point is reached, the cohesion may not be sensibly increased until some disturbing cause operates. The modifications of cohesive attraction are the cause of those different properties of bodies which are called tenacity, hardness, ductility, and elasticity, and will be treated under their appropriate heads, and in the article Strength of Materials.

COHOES, a city of Albany co., New York, on the right bank of the Mohawk river, at its confluence with the Hudson, and on the Erie canal near its junction with the Champlain canal, 8 m. N. of Albany; pop. in 1850, 4,229; in 1860, 8,800; and in 1870, 15,357, of whom 7,947 were natives and 7,410 foreigners. Cohoes falls, 70 ft. in perpendicular height, and remarkable for their picturesque beauty, are just above the city. The Albany division of the Rensselaer and Saratoga railroad and the Troy and Schenectady (New York Central) railroad pass through Cohoes, and horse cars run to Troy. Among the public buildings, the Roman Catholic church of St. Bernard, built of brick, with high towers, is particularly worthy of mention. It cost $100,000, is finely decorated within, and is furnished with a chime of bells. The Episcopal church of St. John, with the parsonage connected, is of Schenectady blue stone, and cost $75,000. Each of the stained windows illustrates one of the figures in Revelations; and being formed of hammered or rolled glass, by which the light is reflected rather than transmitted, they possess great brilliancy and depth of color.—Cohoes derives its importance from the extent of its manufactures, ample water power being supplied by the falls. The Cohoes company, organized in 1826, and having a capital of $500,000, owns the entire water power of the river from half a mile above the falls to a mile below, the total fall in this distance being 120 ft. A stone dam, 1,443 ft. long, was built in 1865 above the falls, at a cost of $180,000. This structure was preceded by a series of wooden dams, the first of which was erected in 1831. The water is used in five successive canals, having falls of 18 to 25 ft.; and again from the level of the state dam below the falls, which was built to supply the canal at this point. The water power is leased by the company at the rate of $20 a year for each horse power, including the necessary land. The Harmony company, having a capital of $2,000,000, owns all the cotton factories in Cohoes, and its mills, comprising six distinct factories, are the largest in the city, the most recent containing 2,700 looms and 130,000 spindles. One of these mills (the first in the United States) has lately been supplied with machinery for

making cotton printing cloths of a yard in width, having the same texture as those of the English mills. In 1871, 4,400 looms and 230,000 spindles were in operation in all the mills; the number of hands was 3,100, of whom two thirds were women and girls; number of water wheels, 15, of 3,000 horse power. To July 1 of that year $1,750,000 had been expended for machinery and $2,275,000 for real estate. The average monthly product is 5,500,000 yards of cloth. In 1870, 52,342,000 yards were manufactured, worth $4,053,254; amount of cotton consumed, 9,012,000 lbs., worth $2,545,887; wages paid, $855,350. The company have recently erected a large brick depot on the New York Central railroad, capable of containing 15,000 bales of cotton. They own large storehouses, and 700 or 800 dwellings occupied by their employees, which are situated on wide streets, regularly laid out, well paved, lighted with gas, and bordered with trees. Knit goods, including undershirts, drawers, and stockings, are a prominent feature of the industry of Cohoes, which produces a third of all the hosiery manufactured in the country. In 1870 there were 18 knitting mills, with an aggregate capital of $1,157,000, requiring 1,066 horse power; amount of wages paid, $535,362; value of materials used, 1,394,948; value of products, $2,345,226. The first knitting mill in the United States was established here in 1832, but it is only within a few years that the business has assumed its present proportions. The Cohoes rolling mill occupies an area of 500 by 160 ft., and produces shafting, bar and band iron, and a superior quality of axe, pick, and mattock poles, as well as an excellent iron for tool makers, which is said to have superseded to some extent the Norway iron formerly used. In 1870 this establishment produced 2,500 tons of band iron and 8,000 axe poles, of the aggregate value of $299,000. There are two axe factories, producing articles to the value of $380,000. The Empire pin company has a capital of $25,000, and in 1870 manufactured 175,000 packages of pins, worth $38,359. A new factory 40 by 100 ft., and six stories high, has recently been erected by the company. The Cohoes knitting-needle factory in 1870 produced 2,804,000 dozen needles, worth $14,450. Besides the establishments mentioned, there are two foundries, three machine shops, a planing mill, a sawing and bevelling establishment, a paper mill, and manufactories of straw board, bedsteads, and tape. The city contains two banks, with an aggregate capital of $350,000. It is divided into four wards, and is governed by a mayor, who, together with the board of aldermen, consisting of two members from each ward, constitute the common council. The public schools, under the control of two commissioners in each ward, are 22 in number, including a high school, and have 28 teachers and 1,430 pupils. There are night schools for the operatives. The Harmony company supports a Sunday school, which has an average attendance of 420 pupils, and is furnished with an elegant school room, a library of 1,800 volumes, and a well appointed reading room. There are also several parish schools, and two weekly newspapers. There are 7 churches, of which 2 are Roman Catholic. One of the Catholic churches is supported by French Canadians, who are largely represented among the mill hands.—Previous to 1811 the site of Cohoes was a barren waste. In that year the Cohoes manufacturing company was incorporated, "for the purpose of manufacturing cotton, woollen, and linen goods, bar iron, nail rods, hoop iron, and ironmongery;" but it failed about 15 years later. In 1831 the population of the neighborhood did not exceed 150. It was incorporated as a village in 1848, and as a city in 1869.

COHORT, in Roman antiquity, a division of an army, comprising three maniples or six centuries, and being the tenth part of a legion. It contained from 400 to 600 men, according to the number in the legion. There was one cohort (*cohors milliaria*) which had precedence over the others, and consisted of 1,000 select men. It marched in the van, carried the eagle, and was commanded by a tribune of approved valor. Marius, who during the wars with the Cimbri introduced tactical reforms into the Roman army, was the first who organized the legion into ten cohorts. The prætorian cohorts were the special guards successively of the generals, triumvirs, and emperors, and exerted great influence during the decline of the empire. Augustus organized nine of them, which he retained as a standing army in the vicinity of Rome, under the command of two prefects. Tiberius placed them under a single prefect, and gave them a fortified camp within the walls. (See PRÆTORIANS.)—When Napoleon organized the legion of honor, he divided it into 16 cohorts.

COHOSH, an Indian name applied to *cimicifuga racemosa* (Gray), or black snakeroot, a plant of the order *ranunculaceæ*. Two varieties of *actæa spicata* are known respectively as red and white cohosh. The black snakeroot has a perennial root and herbaceous stem, which rises to the height of 4 to 8 ft., and grows in shady woods from Canada to Florida. Its physiological action has not been well determined, but it is regarded as a stimulant tonic, and is said to diminish



Cohosh (Actæa spicata).

both the force and frequency of the pulse. It has been used in a great variety of diseases, most frequently perhaps in rheumatism and cholera, and has had a reputation in snake bites. Cimicifugine is a name improperly applied to an impure resin derived from this plant.—The name cohosh, or blue cohosh, is also given to *caulophyllum thalictroides* or pappoose root.

COIF, a head dress. In the middle ages a defensive covering for the head was called by this name, but it was applied more particularly to the covering for the shaven crown of the priests, and to the cap of the advocates. A barrister becoming a sergeant is said to be advanced to the degree of the coif, and takes position accordingly.

COIMBATORE, or **Coimbatoor. I.** A district of British India, in the presidency of Madras, between lat. 10° 14′ and 12° 19′ N., and lon. 76° 36′ and 78° 16′ E.; area, 8,099 sq. m.; pop. in 1871, 1,754,705. The district is enclosed on the north by the group of mountains bordering the table land of Mysore, and on the south by the Pulnai or Vurragiri mountains, and by the Animali range. The principal rivers are the Cavery, Bhowani, Noyel, and Ambrawutty. Although the climate is rendered insalubrious by several extensive morasses, it is better than that of the maritime parts of the Carnatic. Elephants abound. The vegetable productions consist mainly of dry grains. Among the productions are gram, various sorts of panic and of millet, turmeric, and tobacco. Teak and other valuable timber is produced, as well as castor oil and cotton; the last two articles form the principal exports. Experiments have been made with American cotton and Mauritius sugar, proving the fitness of the soil for their cultivation. The language spoken is the Tamil. **II.** The capital of the district, a well built town, occupying an elevated and dry situation on the banks of the Noyel, on the railway from Madras to Beypoor, 268 m. S. W. of Madras, and 600 m. S. S. E. of Bombay; pop. about 20,000. It contains a mosque built by Tippoo Sultan, who made this place one of his principal military stations. About 2 m. from the town, at Peruru, is a Hindoo temple, called Mail Chittumbra. It is roughly constructed, but covered with a profusion of Hindoo ornaments. Some time ago an ancient tumulus near Coimbatore was opened, and found to contain various weapons and other articles, such as were formerly in use among the Romans. The town was twice taken by the British: once in 1783, and again in 1790. A detachment of native infantry is stationed here. The European quarter is eastward and detached from the town.

COIMBRA, a city of Portugal, capital of the province of Beira, 120 m. N. N. E. of Lisbon; pop. about 19,000. It is situated on the river Mondego, in the midst of a mountainous but fertile and well cultivated tract. Its principal public building is the university, the only one in Portugal, founded at Lisbon in 1291, and transferred hither in 1308. It consists of 18 colleges, is divided into 6 faculties, employs 33 professors in ordinary and 22 assistant professors, has a library of over 30,000 volumes, and is attended by about 1,500 students; it is highly endowed, the courses of study are long, and the annual examinations are said to be severe. Coimbra is the seat of a bishopric, and has the wealthy Augustinian convent of Santa Cruz, with its immense Gothic structure. There are also a college of arts belonging to the Jesuits, a cathedral, eight churches, and several monasteries. On a hill near Coimbra is the splendid convent and church of the nuns of Santa Clara,

Plaza, Coimbra.

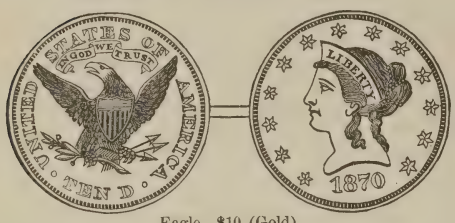
and in the valley of the Mondego opposite to it is the Quinta das Lagrimas, famed in poetry as the scene where Ines de Castro was slain. Seven kings of Portugal were born and four died here, and several princes derived their title from the town. Coimbra is said to be the Conimbrica of the Romans. It sustained many sieges in mediæval times.

COIN, a town of Andalusia, Spain, in the province and 20 m. W. of the city of Malaga; pop. about 8,500. It is well built, has good streets and squares, and a promenade with a fountain. Besides two large churches, there are several chapels and convents, an episcopal palace, and a number of schools. In the vicinity are pleasure grounds and gardens, and in the adjoining hills are marble quarries and great quantities of jasper. Paper, linen, woollens, and other articles are manufactured, and the principal articles of trade are cattle, cereals, fruits, and wine. An annual fair is held in August.

COINS (Fr. *coin*, a die or stamp), metallic money; specie; pieces of metal, generally gold,

silver, or copper, bearing certain marks or devices to indicate their origin and value, and designed to be used as money. How early gold and silver began to be used as money, history does not inform us. Nearly 2,000 years before Christ Abraham returned from Egypt "very rich in cattle, in silver, and in gold;" and in his purchase of the cave of Machpelah, he weighed out the consideration agreed upon, "400 shekels of silver, current money with the merchant." The use of the metals, however, in the form of wedges or bars, though an immense improvement upon simple barter, or the use of cattle, grain, and other commodities, was still attended with inconveniences. At every transaction the precise weight of metal must be computed; a hammer and chisel must be at hand to cut it off, and a balance to weigh it. The fineness of the metal was also to be ascertained. All these troubles were at length ended by the expedient of shaping the metals into pieces of convenient size, and stamping upon each its exact value. He who first did this was the inventor of coins; but history is silent respecting his name, his country, or the date of his invention. Homer, although he speaks of workers in metals, makes no mention of coined money. Herodotus says that the Lydians, as far as he knew, were the first who struck money; and although the oldest specimens of coin now extant have usually been supposed to be Grecian, there are reasons for thinking with Herodotus that the invention was Asiatic. Coins were probably used as early as the 8th century B. C., and by the 4th century money was found throughout the civilized world, every state having its proper coinage.—Most of the commoner metals have in turn been used for making coins. The early coins of Asia Minor were of electrum, a mixture of gold and silver, in the proportion of three of the former to one of the latter. Lycurgus banished gold and silver, and made the money of Sparta of iron, $100 worth of which required a cart and two oxen to remove it. Copper formed the early money of the Romans; and when Cæsar landed in Britain, coins of brass and iron were found in use. Tin was coined by Charles II., and James II. even resorted to gun metal and pewter. At the present day, however, the precious metals, gold and silver, with copper for the lowest denomination, are almost universally employed as the material of coins. Coins of platinum were formerly struck in Russia, but its use for this purpose has recently been abandoned. Gold and silver in a state of purity are soft and ductile; and coins made of these metals would suffer loss and injury to a certain degree by abrasion, if there were no means of hardening them. The addition of a small quantity of alloy is found to produce this effect, without materially impairing the ductility or beauty of the metals. Although in a few countries coins are issued of almost absolute purity, such as the gold sequins of Tuscany and the silver florins of Hanover, yet for the most part the coins of the world consist not of pure gold and silver, but of these metals alloyed with some other, generally copper, in definite proportions fixed by law. The difficulty of ridding gold entirely of the silver with which it is always found combined in nature has led in some countries to the practice of leaving enough silver to serve for alloy. This is the case in Spanish America, as is indicated by the paleness of their doubloons. In some European countries the silver is entirely removed, and copper introduced for alloy, giving to the coins a reddish cast. In the United States the practice of the mint is to imitate the true color of gold in the coinage, by using an alloy of about $\frac{9}{10}$ copper and $\frac{1}{10}$ silver; that is, in 1,000 oz. of standard gold there are 900 oz. pure gold, 10 oz. silver, and 90 oz. copper.—The term standard, as applied to coins, means strictly the conditions of fineness and weight to which they are required by law to conform. Thus, in the United States, the gold coins must be made of metal consisting of $\frac{900}{1000}$ pure gold and $\frac{100}{1000}$ alloy; in other words, they must be $\frac{9}{10}$ fine. This is the standard fineness, and gold of this quality is called standard gold. The weight of such gold required by law in each gold coin is its standard weight. Thus in the eagle there must be 258 grains. In estimating the value of coins, it is the quantity of fine metal contained in them which is considered; the alloy goes for nothing. The practice of the world is not uniform in regard to standard fineness of coins; some countries issuing coins of as low fineness as 250 thousandths, and others aiming at absolute purity. Great Britain still retains the old proportion of $\frac{1}{12}$ alloy; while in the United States, France, Spain, Belgium, and some other countries, the decimal proportion of $\frac{1}{10}$ alloy has been adopted. Different modes of expressing the fineness of coins and bullion prevail in different countries. Where the decimal system of notation is employed, it is expressed in thousandths. Thus the standard fineness of $\frac{9}{10}$ would be written $\frac{900}{1000}$, or simply ·900; and bullion containing three fourths pure metal would be said to be ·750 fine. In Great Britain two systems prevail, one for gold and one for silver. The fineness of gold is expressed in carats, absolute purity being 24 carats fine. The standard fineness of British gold coins is 22 carats, which is equivalent to $\frac{11}{12}$, or $916\frac{2}{3}$ thousandths; so that if a given weight of American gold coin is worth $54, the same weight of British coin is worth $55. For the purpose of expressing minute degrees of fineness in bullion, the carat is divided into four carat grains, and these again into quarters. At the British mint, assays are carried to the half quarter, or the $\frac{1}{32}$ part of the carat. In this system the United States standard of $\frac{900}{1000}$ would be expressed $21\frac{9}{32}$ carats. The fineness of silver is estimated by stating the number of ounces of fine silver in a pound troy of the metal. Thus pure silver is 12 fine; and English silver coins are $11\frac{1}{10}$ fine, because in a pound troy of

standard silver the law requires $11\frac{1}{10}$ oz. pure silver and $\frac{9}{10}$ of an oz. alloy. Thus it will be seen that while the British standard for gold coins is $916\frac{2}{3}$ thousandths, that of silver coin is 925 thousandths.—Coins are generally made flat, circular, and thin. By being flattened they receive better impressions, and are conveniently handled and piled. The circular form simplifies the process of fabrication, diminishes the abrasion to which the coins are subjected in circulation, and fits them for being carried in the pocket. Though the circular form was aimed at in ancient coinage, it was not till the 7th or 8th century that a true circle was attained. This is effected by striking the coin in a ring or collar. The exceptions to the circular form are not numerous. We have, however, the square ducat of Nuremberg, the square rupees of the Mogul empire, the parallelograms of Japan, the octagonal pieces of Assam, and the $50 octagons which were formerly struck in California. The thickness of coins is generally proportioned to their diameter, though in this particular there is great variety. The size of coins is also exceedingly variable. In the United States silver coins range from the three-cent piece to the dollar, or from $11\frac{1}{2}$ grains to $412\frac{1}{2}$ in weight, and from about $\frac{1}{2}$ inch to $1\frac{1}{2}$ inch diameter. Gold coins range from the dollar of $25\frac{8}{10}$ grains to the double eagle of 516 grains. The cent coin (copper and nickel), issued under the act of 1857, is about three fourths of an inch in diameter, and weighs 72 grains, while the bronze cent, under the act of 1864, weighs only 48 grains, but retains the same diameter.—The impressions upon coins present an endless variety. In monarchical countries the obverse of the coin usually bears the likeness of the reigning sovereign, and from this circumstance that side of the coin is in common parlance called the head. In republics it is usual to substitute some device emblematic of liberty. This is often a female figure, or head, with a *pileus*, or Roman liberty cap. The date is also placed upon the obverse in coins of the United States. The reverse of a coin commonly exhibits in the centre the national shield, or the denomination of the piece surrounded by a wreath. Running round the coin near the border, there is usually inscribed the name of the country in which it was struck. It is customary also in countries having more than one mint to distinguish the coinage of each by a letter or monogram. The several branches of the mint of the United States, at Charlotte, Dahlonega, New Orleans, and San Francisco, used to employ for this purpose the initials C., D., O., and S., respectively, coins from the mint at Philadelphia having no mark; but since the civil war no coinage has been executed at Charlotte, Dahlonega, or New Orleans, and the mints at the last two places have been discontinued by the coinage act of 1873, that at Charlotte being retained as an assay office only. In the United States the power to coin money is vested by the constitution in congress, and is prohibited to the separate states; and yet individual citizens are left perfectly free to coin money, provided only that the coins thus made be not in "resemblance or similitude" of the gold or silver coins issued from the mint. In the case of copper coins, however, in addition to the penalties of counterfeiting, the offering or receiving any other copper coin than the cent and half cent is prohibited by fine and forfeiture. Very large amounts of private gold coins have been struck and extensively circulated in different parts of the country. Such were the coins issued by Reid of Georgia, the Bechtlers of North Carolina, the Mormons in Utah, and several private mints in California.—The earliest coinage for America is said to have been made in 1612 for the Virginia company, at the Somers islands, now called Bermudas. The coin was of brass, with the legend "Sommer Island," and a "hogge on one side, in memory of the abundance of hogges which were found on their first landing." On the reverse was a ship under sail firing a gun. As early as 1645 the assembly of Virginia, "having maturely weighed and considered how advantageous a quoine current would be to this collony, and the great wants and miseries which do daily happen unto it by the sole dependency upon tobacco," provided by law for the coinage of copper pieces of 2*d.*, 3*d.*, 6*d.*, and 9*d.*; but this law was never carried into effect. The earliest colonial coinage was in Massachusetts, in pursuance of an order of the general court, passed May 27, 1652, which established "a mint howse" at Boston. The order required the coinage of "12 pence, 6 pence, and 3 pence pieces, which shall be for forme flatt, and stamped on the one side with N. E., and on the other side with XII*d.*, VI*d.*, and III*d.*, according to the value of each peece." These coins were to be of the fineness of "new sterling English money," and every shilling was "to weigh threepenny troy weight, and lesser peeces proportionably." They were soon after in circulation; but owing to the excessive plainness of their finish, they were found to be greatly exposed to "washing and clipping." To remedy this, the general court, on Oct. 19 of the same year, ordered a new die, and required that "henceforth both shillings and smaller peeces shall have a double ring on either side, with this inscription, (Massachusetts), and a tree in the centre, on the one side, and New England and the date of the year on the other side." In 1662 a twopenny piece was added to the series. These coins are now known as the "pine tree shilling," &c. The Massachusetts mint existed about 34 years; but all the coins issued bear only the dates 1652 and 1662, the same dies having probably done service throughout the period. In the reign of William and Mary copper coins were struck in England for New England and Carolina, having on the obverse an elephant, and on the reverse respectively, "God preserve New



England, 1694," and "God preserve Carolina and the lords proprietors, 1694." As early as 1662 an act was passed by the provincial assembly of Maryland "for the getting up of a mint within the province." It is probable, however, that the mint was never established; but shillings, sixpences, and fourpences of silver were made in England under the direction of Lord Baltimore, and sent to the colony, having on the obverse a profile bust of Lord Baltimore, with the legend *Cæcilius: Dns: Terræ: Mariæ:* &c.; reverse, an escutcheon with family arms, value of the piece, and the legend, *Crescite: et: Multiplicamini.* There were also copper halfpennies with the same obverse, and having on the reverse the legend, *Denarivm: Terræ-Mariæ*, and in the centre two flags on a ducal coronet. New Hampshire legislated for a copper coinage in 1766; but, as in the case of Virginia and Maryland, nothing more was done. In the reign of George I. an attempt was made to introduce into general circulation in the colonies coins made of Bath metal or pinchbeck, having on the obverse the head of that king and the legend, *Georgius D. G. Mag. Bri. et Hib. Rex;* and on the reverse a large double rose with the legend *Rosa Americana, Utile Dulci*, 1722 and 1723, in the last the rose being crowned. These coins were made by William Wood, under a royal patent "for coining small money for the English plantations, in pursuance of which he had the conscience to make 13 shillings out of a pound of brass." This "Wood's money," however, was vehemently rejected both here and in Ireland, where strenuous efforts were made to introduce it. From 1778 to 1787 the power of coinage was exercised not only by the confederation in congress, but also by several of the individual states. In Vermont a mint was established by legislative authority in 1785, in the town of Rupert, and copper cents were issued of the following description: Obverse, a sun rising from behind hills, and plough in the foreground, with the legend, *Vermontensium Res Publica*, 1786; reverse, a radiated eye surrounded by 13 stars, with the legend, *Quarta Decima Stella.* Some of the cents of 1786 and all those of 1787–'8 have on the obverse a head, with the legend, *Auctoritate Vermontensium*, and on the reverse a woman, with the legend, *Inde. Et Lib.* Connecticut followed the example of Vermont, and in the same year, 1785, authorized the establishment of a mint at New Haven, and copper coins were issued, weighing six pennyweights, and having on the obverse a head with the words *Auctori. Connec:* reverse, a female figure holding an olive branch, with the legend, *Inde. Et Lib.* 1785. This mint continued in operation three years. New Jersey authorized a copper coinage in 1786. The parties procuring the patent established two mints, one at a place known as Solitude, about two miles west of Morristown, and the other at Elizabeth. The coins are thus described: Obverse, a horse's head with a plough beneath—legend, *Nova Cæsarea*, 1786, &c.; reverse, a shield—legend, *E Pluribus Unum.* Massachusetts, by act of Oct. 17, 1786, directed the establishment of a mint, and the following year the necessary works were erected on Boston neck and at Dedham. In 1788 cents and half cents were issued, exhibiting on the obverse the American eagle with arrows in the right talon and an olive branch in the left, a shield on its breast bearing the word "Cent"—legend, "Massachusetts, 1788;" reverse, an Indian holding a bow and arrow—legend, "Commonwealth" and a star.—As early as January, 1782, a plan for an American coinage was submitted to congress by Robert Morris, the head of the finance department, the authorship of which is, however, claimed for Gouverneur Morris. In February following congress approved the establishment of a mint, but no further action was taken till 1785, when congress adopted the plan of a national coinage presented by Thomas Jefferson, and in 1786 decided upon the following names and characters of the coins: An eagle, to contain $246\frac{2}{10}\frac{6}{0}\frac{3}{0}$ grs. of fine gold, value $10, and half eagle in proportion, both to be stamped with the American eagle; a dollar, to contain $375\frac{6}{1}\frac{4}{0}\frac{}{0}$ grs. of fine silver; a half dollar, double dime, and dime, in proportion. The copper coins were a cent and half cent. In October, 1786, congress framed an ordinance for the establishment of a mint; but nothing further was done till 1787, when the board of treasury, by authority of congress, contracted with Mr. James Jarvis for 300 tons of copper coin of the federal standard. These cents were coined at the New Haven mint, and are of the following description: On one side, 13 circles linked together, a small circle in the middle with the words "United States" around it, and in the centre the words, "We are one;" on the other side, a sun-dial with the sun above it, and *Fugio*, 1787, on opposite sides, and below the dial, "Mind Your Business." A few of these pieces are said to have been struck in the Vermont mint at Rupert. On April 2, 1792, a code of laws was enacted for the establishment and regulation of the mint, under which, with slight amendments, the coinage was executed for 42 years. The denominations of coin and their rates were as follows: Gold, the eagle of $10, to weigh 270 grs., the half eagle and quarter eagle in proportion, all of the fineness of 22 carats, or $916\frac{2}{3}$ thousandths; silver, the dollar of 100 cents, to weigh 416 grs., the half dollar, quarter dollar, dime of 10 cents, and half dime in proportion, the fineness to be 1,485 parts fine in 1,664, or 892·4 thousandths; copper, the cent of 264 grs., the half cent in proportion. The same act declared the dollar to be the unit of federal money, and directed that all public accounts should be kept in conformity to the decimal system of coins above described. After the act of 1792 the following changes in the currency occurred: Jan. 14, 1793, the cent reduced to 208 grs., and half

cent in proportion; Jan. 26, 1796, cent reduced to 168 grs., and half cent in proportion; June 28, 1834, the weight of the eagle reduced to 258 grs., and the parts in proportion, of which 232 grs. were to be fine gold, equal to a fineness of $899\frac{225}{1000}$ thousandths, being an increase of $6\frac{68}{100}$ per cent. on the former value of gold as compared with silver, which remained unchanged. The disadvantages of the complex standards both of gold and silver determined Mr. R. M. Patterson, the director of the mint, to attempt an improvement. He accordingly drew up a well considered code of mint laws, which was enacted by congress, Jan. 18, 1837, by which the French standard of fineness of $\frac{900}{1000}$, for both gold and silver, was adopted. The weight of the gold coins remained unchanged, but the dollar was reduced to $412\frac{1}{2}$ grs., and the lesser silver coins in proportion. By the act of March 3, 1849, there were added to the series of gold coins the double eagle and the dollar; and by act of Feb. 21, 1853, the three-dollar piece. By act of March 3, 1851, there was added to the silver coins a three-cent piece (a legal tender for sums not exceeding 30 cents), of the fineness of $\frac{750}{1000}$, and $12\frac{3}{8}$ grs. in weight, at which rates it continued to be coined till April 1, 1853, when its fineness was raised to ·900, and its weight reduced to $\frac{3}{50}$ of the half dollar, or $11\frac{52}{100}$ grs. At this date also, in pursuance of the act of Feb. 21, 1853, an important change was effected in the silver coinage. The preëxisting laws had made both gold and silver coins (except the three-cent piece) a legal tender for any amount. At the ratio of silver to gold of 16 to 1, silver was undervalued in the United States as compared with Europe, and our silver coins were largely exported. The remedy provided was a seigniorage upon the silver coins, and making gold alone the legal tender. The weight of the half dollar was reduced from $206\frac{1}{4}$ grs. to 192 grs., and the smaller coins in proportion. The mint ceased coining silver for individuals, but purchased silver at the market price and made the coins for government account—a policy with respect to silver which was adopted in England as early as 1817. The effect of this change was to give to the silver coin of the country a current value sufficiently above its market price as bullion to prevent its exportation, and at the same time to make silver money subsidiary to gold. It is a legal tender now only to the extent of $5. The price at which the mint buys silver is fixed from time to time according to its value in the market, and in 1872 was $1 $22\frac{1}{2}$ per standard ounce (·900 fine). The silver dollar was not included in this change. It was still a legal tender for all amounts, and its weight continued at $412\frac{1}{2}$ grs., while that of two half dollars, or an equivalent sum in smaller coins, was 384 grs. It was therefore intrinsically worth $7\frac{42}{100}$ per cent. more than a dollar's worth of the other silver coins; but as compared with their current value, only about $4\frac{1}{2}$ per cent. more. A further change in the currency was effected by the act of Feb. 21, 1857, by which the copper cent and half cent were discontinued, and a new cent, composed of 88 per cent. of copper and 12 per cent. of nickel, and weighing 72 grs., was substituted; which continued to be coined until the act of April 22, 1864, provided for the coinage of the bronze cent, consisting of 95 per cent. of copper and 5 per cent. of tin and zinc, and weighing 48 grs. The same act authorized the coinage of two-cent pieces weighing 96 grs.; and by the act of March 3, 1865, a three-cent coin, three fourths copper and one fourth nickel, weighing 30 grs., was authorized. The act of May 16, 1866, provided for the coinage of a five-cent piece, three fourths copper and one fourth nickel, weighing 77·16 grs. The one- and two-cent coins were made a legal tender only to the amount of 4 cents, while the three-cent and five-cent pieces were a legal tender for sums not exceeding 60 cents and $1 respectively. The act of Feb. 12, 1873, known as the coinage act of 1873, prepared under the supervision of John Jay Knox, comptroller of the currency, and the passage of which was largely due to his exertions, has consolidated the regulations governing the coinage of the United States. Under this act the fineness of all gold and silver coins is to be ·900. The alloy of the silver coins consists of copper; the alloy of the gold coins is copper, or copper and silver, the silver in no case to exceed one tenth of the whole alloy. The gold coins are a one-dollar piece, "which, at the standard weight of 25·8 grs., shall be the unit of value;" a quarter eagle, or two-and-a-half-dollar piece, 64·5 grs.; a three-dollar piece, 77·4 grs.; a half eagle, or five-dollar piece, 129 grs.; an eagle, or ten-dollar piece, 258 grs.; and a double eagle, or twenty-dollar piece, 516 grs. These coins are a legal tender to any amount. The silver coins are a "trade dollar," weighing 420 grs.; a half dollar, or fifty-cent piece, $12\frac{1}{2}$ grams, or 192·9 grs.; a quarter dollar, or twenty-five-cent piece, and a dime, or ten-cent piece, respectively one half and one fifth the weight of the half dollar. These coins are a "legal tender at their nominal value for any amount not exceeding five dollars in any one payment." The trade dollar is intended for the convenience of commerce with China and Japan; while the half dollar, being half the weight of the five-franc silver coin of France, Belgium, and Switzerland, of the five-lire silver coin of Italy, the five-peseta silver coin of Spain, the five-drachma silver coin of Greece, and having the same weight as the new silver florin of Austria, is a step in the direction of international coinage. The minor coins are a five-cent and a three-cent piece, three fourths copper and one fourth nickel, weighing respectively 77·16 and 30 grs., and a one-cent piece, 95 per cent. copper and 5 per cent. tin and zinc, weighing 48 grs., which are a "legal tender at their nominal value for any amount not exceeding 25 cents in any one payment." coins other than those enumerated in the act is prohibited. It is provided that upon the coins of the United States there shall be the following devices and legends: Upon one side an impression emblematic of liberty, with an inscription of the word "Liberty" and the year of the coinage; and upon the reverse the figure of an eagle, with the inscriptions "United States of America" and "E Pluribus Unum," and a designation of the value of the coin; but on the gold dollar and three-dollar piece, the dime, five-, three-, and one-cent piece, the figure of the eagle shall be omitted; and on the reverse of the silver trade dollar the weight and the fineness of the coin shall be inscribed; and the motto "In God we trust" may be added when practicable.—A new coinage has been struck in Germany, having the mark worth 23·8 cents as the unit, which after 1875 is to be the exclusive specie currency of the empire.—In the following table of gold and silver coins of different countries, taken from the annual report of the Hon. James Pollock, director of the United States mint, for the year ending June 30, 1872, the gold values are computed according to the value of United States coins ($18 60·4 per oz. standard); the silver values according to the mint price for that year of silver ($1 22½ per oz. standard).

The following table, compiled from the last report of the director of the mint, exhibits the aggregate United States coinage from the establishment of the mint in 1793 to June 30, 1873:

PERIOD.	Gold Coinage.	Silver Coinage.	Minor Coinage.	Entire Coinage.
1793 to 1817	$5,610,957 50	$8,268,295 75	$319,340 28	$14,198,593 53
1818 to 1837	17,839,382 50	40,566,897 15	476,574 30	58,682,853 95
1838 to 1847	49,554,452 50	22,331,719 00	349,676 63	72,235,848 13
1848 to 1857	408,856,176 14	35,791,307 63	517,222 34	445,164,706 11
1858 to 1867	403,717,501 97	30,956,287 51	5,752,310 00	440,426,099 48
1868	24,141,235 06	1,592,986 48	1,713,385 00	27,447,606 54
1869	32,031,126 43	1,575,619 05	1,279,055 00	34,885,801 48
1870	29,931,739 78	2,474,658 54	611,445 00	33,017,838 32
1871	34,388,137 12	5,518,501 70	283,760 00	40,190,598 82
1872	36,193,073 77	13,421,779 37	123,020 00	49,737,773 14
1873	55,744,953 61	9,967,710 00	494,050 00	66,206,713 61
Total	$1,097,683,511 22	$172,392,780 23	$11,919,838 55	$1,281,996,130 00

Of the total gold coinage, $280,805,517 85 consisted of bars; the silver bars amounted to $27,770,503 66. The number of gold coins struck was 181,673,669; silver coins, 524,624,186; minor coins, 674,597,467, of which 105,522,000 were five-cent pieces, 26,845,000 three-cent pieces, 45,601,000 two-cent pieces, 488,644,244 one-cent pieces, and 7,985,223 half-cent pieces. —For the process of coinage, see MINT; and for ancient coins, NUMISMATICS.—The subjoined tables exhibit the comparative value of the coins of different countries and ages. The tables of ancient coins are those of Dr. Arbuthnot, whose authority, however, has been called in question.

1344 192 96 48 24 12 6 4 2 Tetradrachma	2 7 0	0 62·64
1680 240 120 60 30 15 7½ 5 2½ 1½ Pentadrachma	3 2 3	0 78·31

Of these, the drachma, didrachma, &c., were of silver, the rest for the most part of brass. The drachma is here, with most authors, supposed equal to the denarius; though there is reason to believe that the drachma was somewhat heavier.

	£ s. d.	$ cts.
The Grecian gold coin was the stater aureus, weighing 2 Attic drachmas, or half of the stater argenteus, and exchanging usually for 25 Attic drachmas of silver	0 16 1½	3 91·5
But according to our proportion of gold to silver, it was worth	1 0 9	5 03
There were likewise the stater Cyzicenus, exchanging for 28 Attic drachmas, or	0 18 1	4 38·5
The stater Philippicus and stater Alexandrinus were of the same value.		
The stater Daricus, according to Josephus, was worth 50 Attic drachmas	1 12 3½	7 83
The stater Crœsius was of the same value.		

ROMAN COINS.

NAMES AND PROPORTIONS.	Value in English money.	Value in U. S. money.
	s. d. qrs.	$ cts.
Teruncius	0 0 $0^{775}/_{1000}$	0 00·3915
2 Sembella	0 0 $1^{55}/_{100}$	0 00·783
4 2 Libella As	0 0 $3^{1}/_{10}$	0 01·566
10 5 2½ Sestertius	0 1 $3^{3}/_{4}$	0 03·91
20 10 5 2 Quinarius, or Victoriatus	0 3 $3^{1}/_{2}$	0 07·83
40 20 10 4 2 Denarius	0 7 3	0 15·66

The denarius and quinarius were of silver; the other coins were also of brass or copper, the three smaller being generally of the base metals.

	£	s.	d.	$ cts.
The Roman gold coin, or aureus, weighed generally double the denarius; its value, according to the proportion of gold to silver mentioned by Pliny, was	1	4	3¼	5 89·6
According to the proportion that now obtains among us	1	0	9	5 03
According to the decuple proportion mentioned by Livy and Julius Pollux	0	12	11	3 13·2
According to the proportion mentioned by Tacitus, by which the aureus exchanged for 25 denarii, its value was	0	16	1¼	3 91·5

An English writer says of these tables of ancient coins that they "are constructed on the hypothesis that the consular denarii weighed by Greaves were of the same purity as English standard silver, and that no subsequent diminution was made either in their weight or fineness. The conclusion derived from such data, though differing in degree, are of the same character as those which we should arrive at if, in estimating the value of the pound sterling during the last 100 years, we took for granted that it contained a pound weight of standard silver, as in the period from the conquest to the reign of Edward I."

COIRE, or **Chur** (Romansch, *Cuera ;* anc. *Curia Rhætorum*), a town of Switzerland, capital of the canton of Grisons, 59 m. S. E. of Zürich; pop. in 1870, 7,552. It occupies a picturesque site at the mouth of the defile of the Plessur, about a mile from the Rhine, and is the principal depot on the route from Italy into Switzerland and western Germany by the Splügen and Bernardino passes. The church of St. Lucius and the bishop's palace are curious old buildings, portions of which date back to the 8th century or earlier. There are also a town hall, public library, Catholic seminary, and cantonal schools. It is the seat of probably the oldest bishopric in Switzerland, dating from the 5th century. The Romansh, a corruption of Latin, is spoken here, and a newspaper is published in that tongue. It is the birthplace of the painter Angelica Kauffman.

COIT, Thomas Winthrop, an American clergyman, born in New London, Conn., June 28, 1803. He graduated at Yale college in 1821, entered the ministry of the Episcopal church, and became rector of St. Peter's church, Salem, Mass., in 1827, and two years later rector of Christ's church, Cambridge. In 1834 he was elected president of Transylvania university, Lexington, Ky. This office he resigned in 1839, and became rector of Trinity church, New Rochelle, N. Y., which position he held for about ten years. In 1854 he was elected professor of ecclesiastical history in Berkeley divinity school, Middletown, Conn., the duties of which post he discharged in connection with the rectorship of St. Paul's church, Troy, N. Y. He resigned the rectorship in 1872, and has been since chiefly occupied in the duties of his professorship. Dr. Coit ranks among the foremost of living scholars in the Episcopal church, and is the author of several able works in defence of its doctrines and position. Besides a large number of occasional addresses and sermons, and contributions to the "Church Review," he has published "A Theological Commonplace Book;" "The Bible and Apocrypha in Paragraphs and Parallelisms" (2 vols., 1834); "Remarks on Mr. Norton's Statement of Reasons" (1834); "Townsend's Chronological Bible" (2 vols., 1837); "Puritanism, a Churchman's Defence against its Aspersions" (1844); "Lectures on the Early History of Christianity in England" (1859); and a report on the "Standard Prayer Book" (1868).

COJUTEPEC, or **Cojutepeque,** a town of San Salvador, Central America, in the department of Cuscatlan, a few miles N. of a lake of the same name, and about 15 m. E. of San Salvador; pop. 15,000. It was the seat of government from 1854 to 1858, San Salvador, the capital, having been destroyed by an earthquake in the former year. The country around it is volcanic. Lake Cojutepec, sometimes called Ilopango, is 12 m. long and 5 m. broad. It is surrounded by high abrupt hills, and is probably the crater of an ancient volcano. It receives no tributary streams, but has a small outlet flowing through a deep ravine into the Rio Jiboa, near the base of the volcano of San Vicente. After a gale its waters assume a dark greenish hue and exhale a disagreeable sulphurous odor, and dead fish are cast ashore in large numbers.

COKE, the solid product left behind when the volatile matters are expelled by distillation from bituminous coal. There are two kinds: gas coke, obtained from the retorts of gas works after the gases have been separated; and oven coke, which is made in ovens or pits, and which is considered by manufacturers as the only true coke, gas coke being merely cinder. Oven or pit coke is made upon a large scale at mines of bituminous coal, for the purpose in part of saving the fine refuse coal by converting it into a valuable fuel, and in part of converting the lump coal into a form better adapted for metallurgic operations, and for the use of locomotives when the flame and smoke of bituminous coal would be objectionable, as upon underground railways and in populous streets. It was formerly the opinion of some engineers that the calorific qualities of bituminous coal exist undiminished in the coke, notwithstanding that the gases expelled in the process of making the coke possess also a considerable heating power. Mr. Josiah Parker states, in vol. ii. of the "Transactions of the Institution of Civil Engineers," that he has "found that 75 lbs. of coke, produced from 100 lbs. of coal, evaporated as much water as 100 lbs. of the self-same coal." He also cites the experience of Mr. Apsley Pellatt in his glass furnaces, which were especially well adapted for showing the relative calorific value of coke and coal, provision being made in them for the full combustion of the volatile products of the coal. Of late years, however, after much discussion upon the subject, bituminous coal has come into use in place of coke upon the prin-

cipal railway lines in England, the use of the latter being retained only when flame and smoke require to be avoided. Coke has never been used on American railroads, and now that locomotives are so constructed that crude coal can be burned with facility and economy, the occasion will probably never arise. In consequence of its freedom from sulphur, coke is much better adapted to metallurgic processes, and therefore special attention has been directed in Europe, not only to the best methods of preparing it, but to the selection of that kind of coal which is best adapted to the purpose; and it has been found in practice preferable to incur considerable expense to procure it of the best quality, some companies even preferring to obtain it from England rather than use the cheaper but inferior qualities made from the coals of France and Belgium. The cause of the superiority of the English coke is attributed to the coal beds of England containing but few seams of slate interstratified with the coal; so that this is obtained clear of the impurities which in the French and Belgian coals add largely to the proportion of ash, and render it necessary to subject the coal to processes of washing and sorting before coking. Iron pyrites is the principal objectionable material in coal for melting metals, and to get rid of it is the chief problem of the coke maker. A protracted application of heat expels a great part of the sulphur, with the formation of bisulphide of carbon and carburet of iron. The bisulphide of carbon, being volatile, passes off, and the carburet of iron which remains does no injury unless there is silica present, which is not the case in good coking coal. In the north of England it has been found that when the coal contains much pyrites, if it is first treated with a very strong brine the elimination of the sulphur is very greatly facilitated. The tendency to vitrifaction possessed by clays and lime salts renders these substances objectionable in coke, and therefore good coking coal is only found in certain districts. (See Coal.)—Two methods of coking are in use: one in ovens constructed for the purpose, and the other in large open heaps, upon the ground. The ovens are built of fire brick or stone of various sizes, and frequently arranged several together in one stack, in which case dimensions of 12 ft. square and 10 ft. high are found most convenient. They are arched over at the top, a hole being left for the exit of the gases, and another for the introduction of the coal, closed by an iron door in front. About two tons of coal are introduced through the latter, filling the oven to the springing of the arch, and leaving room above for the coal to swell. The charge is ignited by the heat left in the walls by the process just previously completed. Air is allowed to enter in proper quantity at the lower door, and the gases escape at the top. In 24 hours the air holes below are closed, and for 12 hours more the gases pass out at the top. The upper hole is then closed with a slab of stone or iron and covered with sand, and left for 12 hours more to partially cool down the charge. After this the door below is opened, the coke taken out quickly, quenched with water, and carried off in iron wheelbarrows. Where it is an object to save the coal tar, the ovens are provided with a flue at the top, through which the volatile products are conducted into a receptacle in which the liquid matters are condensed. The product of bituminous coal in coke, gas, and tar varies with its quality. As it approaches anthracite in quality, the yield of coke is large and of gas small, while the reverse is the case with the fat or highly bituminous coals. From 50 to 75 per cent. is the general range of the yield of coke. Upon some of the railroads in England the size of the ovens is stated to be 30 ft. square, and the charges about 8 tons each, spread in a thickness of about 4 ft. The duration of the process is 96 hours. With the same coals and ovens, by making the charges lighter and increasing the quantity of air admitted, and thus raising the temperature, so as to complete the process in 48, 24, or even 12 hours, the coke will be obtained lighter and more friable according as it may be desired. It has been found that the higher the heat of the oven the larger the yield of coke. This fact seemed for a long time anomalous, but is explained by well known chemical laws. When coal is melted, its hydrogen and carbon combine in the form of bicarburetted hydrogen, which in passing up through the red-hot coal above is decomposed into solid carbon and light carburetted hydrogen. Thus one half of the carbon of the gas is saved. The principle is illustrated by passing bicarburetted hydrogen through a red-hot tube, which after a while will become filled with a solid carbonaceous deposit.—Coking in the open heap is the most common practice at the mines of bituminous coal of the United States, and this is the oldest method. The coal is piled up in long ranges, extending sometimes 200 ft. in length, with a width of 12 ft. at the base, and a height of 6 ft. The piles are made so that along the whole length an air passage extends through the centre on the ground. The largest lumps are placed in the middle portion, and smaller and smaller pieces toward the outside. Stakes are set up at intervals along the central line of the heap, which reach down to the base; when the pile is completed, these are taken out, and the passages they leave serve for the introduction of burning coals to fire the heap along its whole length. Whenever the thick black smoke and flame cease in any portion, and this begins to show appearance of ashes, the fire is kept down by the application of coke dust or ashes; and this goes on until the whole heap is thus covered. It is then left for a few days to cool. Portions exposed to the full action of the wind require, as in the process of making charcoal, a thicker cover of dust or ashes to check the consumption of the product. When sufficiently cool, the coke

is drawn out. The process is not an economical one, much of the inside coal being always consumed to waste before the inner portions have been coked. A method has been adopted at the Clyde iron works in Scotland, by which a part of this waste is obviated. A mound is built up of a circular form around a central chimney of brick, which may be 3 ft. square at the base and rise 3 or 4 ft. from the ground. Openings of the size of a brick are left at intervals in its sides, for the passage of the gases, and from the lowest of these the coal around is so piled that flues extend through it to the circumference of the heap. The diameter of the mound may be 20 ft., and its ashes 4½ ft., sufficient with the cover of ashes and cinders to reach above the top of the chimney. The heap is lighted by burning coals thrown into the chimney, from which the flames reach through the aperture. In four or five days, when the mound has become thoroughly on fire, the apertures on the outside and the top of the chimney are closed with plates and ashes, and the heap is left to cool for three days, after which the coke is drawn out. It is the practice now in Europe to utilize the heat produced in making coke. At some chemical works salt is made by using the waste heat; in blast furnaces the air has been heated from the same source, and in many others the heat from the burning of the escaping gases is used to increase the heat of the coking oven itself. Many of these are in use on the continent of Europe.—A species of coke called "charred coal" is now used in place of charcoal in the manufacture of tin plates. It is made by spreading fine coal on the red-hot floor of a reverberatory furnace to the depth of four or five inches. Much gas is given off and ebullition takes place, producing a spongy mass which is removed after an hour.

COKE, Natural. At the coal mines of the lias formation, on both sides of the James river, and near Richmond, Va., beds of natural coke of good workable quality are met with, interstratified with the slates, sandstones, fire clay, and coal. On the N. side of the river is a bed 5 ft. thick, which lies slightly inclined toward the west. Several vertical shafts cut it, the deepest about 207 ft. below the surface. The coke is of a nearly uniform character, and is heavier than common coke, vesicular in texture, and of a dull black color. The volatile ingredients of the coal are almost wholly wanting, and the coke does not differ in its properties and appearance from much of the more compact artificial varieties. Twenty feet above the coke, the agent which effected this change, and also altered the beds of fire clay and slate, is seen in an intercalated layer of trap rock of 15 to 30 ft. in thickness. Immediately beneath the trap is a bed of carbonaceous fire clay and cinder 5 ft. thick, baked and hardened by the action of the trap. Under the coke bed is another stratum of indurated fire clay, and beneath this one of coal slates 20 ft. thick. Another carbonaceous bed is then cut by the shaft; this is a thin layer of half-coked coal. Twenty feet below this is another coal bed of the usual bituminous composition, its structure unaltered.

COKE, Sir **Edward,** an English jurist, born at Mileham, Norfolk, Feb. 1, 1552, died at Stoke Pogis, Buckinghamshire, Sept. 3, 1633. Nothing of particular interest is related of his school days at the grammar school in Norwich, or in the university of Cambridge. He left Cambridge without taking a degree, and at the age of 20 commenced the study of law at an inn of chancery, where he spent a year in acquiring a knowledge of the forms of writs and proceedings in courts, and then entered upon the study of general jurisprudence in the Inner Temple. He was called to the bar a year before the expiration of the time prescribed for legal studies (at that time seven years), in 1578, and was soon after appointed reader (lecturer) of Lyon's Inn (an inn of chancery), which office he held three years, and so distinguished himself by his lectures that he gained much repute for legal learning. Within that time he rose to the highest rank in the profession by his argument in Shelley's case, the most celebrated case relating to real estate which is to be found in the English reports. He was thenceforth employed in most of the important cases in Westminster, was successively elected recorder of Coventry, then of Norwich, and lastly of London, and was appointed reader (law professor) of the Inner Temple. In 1592 he was, at the instance of Lord Burleigh, appointed solicitor general, and the following year he was returned to parliament as the representative of Norfolk, and was chosen speaker of the house. In 1594, the office of attorney general becoming vacant, Coke expected to succeed to it in regular course, but was unexpectedly met by a formidable claimant, Francis Bacon, backed by the influence of the earl of Essex. Queen Elizabeth resisted the solicitation of her favorite, and appointed Coke; but it was the commencement of bitter hostility between the rivals, which, with alternating success, was ultimately disastrous to both. In 1598 Coke lost his first wife, to whom he had been married 16 years, and within four months married Lady Hatton, a wealthy young widow, who within a year bore to him a daughter, but refused to take his name, being always known as Lady Hatton. In 1600 he published the first of the 11 parts of his reports. The other parts were published in the following reign. The preface is characteristic of the author. He proposes no diminution of the student's labor by any facility which his reports are to furnish. "My advice to the reader," he says, "is that in reading of these or any new reports, he neglect not in any case the reading of the old books of years reported in former ages, for assuredly out of the old fields must spring and grow the new corn." In his subsequent works he often reiterates the same advice. He did not encourage the use of abridgments, except

for reference to the original cases, but insists upon the study of the cases themselves. The trial of the earls of Essex and Southampton for high treason, which occurred early in 1601, brought out harsh traits in the character of Coke. His statement of facts in opening the case was exaggerated, and his manner abusive, and this was continued throughout the trial. In the first year of King James, the trial of Sir Walter Raleigh upon a charge of high treason for a conspiracy to place the lady Arabella Stuart on the throne again exhibited Coke (who still remained attorney general) as a public prosecutor, and on this occasion to arrogance and vituperation he added an unfair attempt to convict the prisoner upon evidence which he knew to be insufficient, and in fact inadmissible. The advancing favor of Bacon with King James now exasperated the former enmity of Coke against him. The literary renown of Bacon, and the personal regard shown for him by Elizabeth, although it had not procured him official station other than the honorary one of queen's counsel, had excited the jealousy of Coke, and sharp encounters had taken place between him and Bacon. As attorney general Coke rendered efficient service in the unravelling of the gunpowder plot and the prosecution of the parties concerned. On the trial Coke opened the case to the jury at enormous length, interlarding his diatribe against the prisoners with quaint conceits. To Sir Everard Digby, one of the prisoners, who confessed the charge, but prayed the mercy of the king as to the mode of death, and also in behalf of his family, Coke answered that he must not look to the king to be honored in the manner of his death, but was rather to admire the moderation of the king in that for so important a crime no new torture answerable thereto had been devised to be inflicted on him. The trial of Garnett, the superior of the Jesuits, who was implicated in the same plot, called forth still greater effort on the part of Coke to show his zeal for the king and severity to the prisoner. — In 1606 Coke was appointed chief justice of the common pleas, and Bacon in 1607 solicitor general. From the time he entered upon his office he exhibited an integrity and independence in striking contrast with his former violation of private rights in his zeal to serve the crown. Indeed, the difference is so great that we hardly recognize Coke the chief justice as the same person with Coke the attorney general. Thus he granted writs of prohibition to restrain the court of high commission from issuing process for the arrest of parties complained against, which practice, recently introduced in place of citation, Coke maintained to be contrary to Magna Charta. He resisted the pretension of King James to the right of sitting in person to hear causes, which was a device suggested for the purpose of getting rid of prohibition and appeal. Prohibitions were also issued from the common pleas to check the arbitrary proceedings of the lord president of Wales, and of the lord president of the North. Complaint having been made to the king of these prohibitions, and the judges having been summoned before the council, Coke justified the judges; and in like manner, when the question came up as to the king's prerogative to impose penalties and otherwise alter laws by proclamation, and the opinions of the judges were demanded by the king for the purpose of enforcing the power claimed, Coke resisted, and finally got the rest of the judges to concur in an answer that a proclamation was no law. The effect of this bold opposition to arbitrary power can hardly be overestimated. It at least checked abuses, and it led to investigation as to the limit imposed by law. Although Coke had but little turn for abstract reasoning about natural rights, he was inflexible in maintaining such rights as had been recognized by law. In 1613 Coke was removed from the office of chief justice of the common pleas to the chief justiceship of the king's bench. The change was intended partly as a penalty for his conduct in the matters before referred to, but chiefly to favor the advancement of Bacon, who wished the place of attorney general, and Hobart, who then held the office, was willing to exchange for the chief justiceship of the common pleas, but not of the king's bench. The reluctance of Coke to leave the common pleas may be explained by the fact that far the larger part of the civil business of the kingdom was transacted in that court, it having exclusive jurisdiction of all cases relating to real property. It appears from a letter of Bacon to the king that it was designed to put Coke upon his good behavior, and to prepare the way for his final dismissal from office if he should fail to become conformable to the views of the court. He was in fact dismissed three years afterward, but in the mean time, with the certainty of losing his place by persistence in the course of judicial independence which he had heretofore pursued, he fearlessly resisted the encroachment of royal prerogative, and the corrupt attempts of court minions to pervert his administration of the law to improper purposes. Two memorable instances occurred of Coke's inflexibility in maintaining what he believed to be right, although exceedingly obnoxious to the king: his contest with the court of chancery, and his resistance of the interference of the king in the matter of the commendams. The court of chancery had exercised the power of correcting judgments of other courts. The limit of this power had not been well defined. There were many cases where, by the rigid practice at common law, great injustice was done, and relief could be had only by the equitable administration of chancery; but some of the chancellors had proceeded as if they had a general right to review the judgments of all other courts. Coke wholly denied the authority of the court as thus claimed. He and his

associate judges declared it to be an indictable offence to question a judgment of the king's bench or common pleas; and an effort was made to get an indictment against the parties, solicitors, and officers of the court of chancery, in two cases in which injunctions had been granted by the chancellor against judgments at law. But as it appeared that gross fraud had been committed in the obtaining of these judgments, the grand jury could not be persuaded to bring in a bill. The proceeding having attracted public attention, the king appointed commissioners to inquire into the subject of dispute. The report of the commissioners sustained the proceeding of the chancellor. Proceedings were thereupon instituted in the star chamber against the private parties concerned in resisting the authority of the chancellor. The conduct of Coke on this occasion has been generally censured; but there can be no doubt that it had the effect of establishing with more precision the rule by which the interposition of the court of chancery should be regulated. The case as to the commendams was this: In a suit against the bishop of Lichfield and Coventry respecting a benefice, the defendant pleaded that he held it *in commendam*, which was an appointment by the king in certain cases until a new incumbent could be regularly appointed. The question was involved as to the right of the king to make such grants. Upon being advised of the discussion, the king sent a message to Coke signifying his pleasure that all proceedings should be stayed till the judges should have a conference with his majesty on the subject. A meeting of all the judges having been held for consultation, it was resolved by them that the court ought to proceed as though they had received no notice, which was accordingly done, and a memorial signed by the 12 judges was sent to the king, in which they say: "We hold it our duty to inform your majesty that our oath is in these express words, 'that in case any letter come to us contrary to law, we do nothing therefore but certify your majesty thereof, and go forth to do the law notwithstanding the same.' We have advisedly considered the said letter of Mr. Attorney, and with one consent do hold the same to be contrary to law, and such as we could not yield to the same by oath." A sharp response followed from the king, ordering the judges to proceed no further till his coming in town. He then called them before him, and commented severely upon their course of proceeding and the form of their letter; upon which the judges kneeled and craved pardon. But Coke, though he expressed sorrow for any error of form, still persisted in defending the substantial right of what he had done. The king himself seems to have been impressed by the noble bearing of the chief justice, for the court was permitted to proceed in the cause of the bishop, which was finally decided against him.—The active measures taken by Coke for the conviction of the murderers of Sir Thomas Overbury gave further offence to James, and he probably intended the removal of Coke upon the first favorable opportunity. This intention was no doubt precipitated by the enmity of the new favorite Villiers, who had been thwarted by the chief justice in a corrupt attempt at the disposition of a lucrative clerkship in the king's bench. The removal was, however, put upon very different grounds. Among the charges which he was required to answer before the council were: 1, the alleged concealment of a bond belonging to the crown; 2, his misconduct in the dispute with the chancellor respecting injunctions; 3, his disrespectful conduct to the king in the matter of the commendams. A few days afterward he was again called before the council, when sentence was pronounced that he be suspended from the council and from his judicial functions till the king's pleasure should be further known, and in the mean time that he should revise his books of reports, wherein it was alleged that "many extravagant and exorbitant opinions were set down for good law." After the summer vacation he was again cited before the privy council to answer as to revision of errors in his reports, when he made a specification, showing that there were not more errors in his 11 books of reports, containing 500 cases, than could be found in a few cases in Plowden. The whole charge was indeed frivolous; but a *supersedeas* nevertheless issued, removing him from his office (1616), and Montague was appointed in his place. Not long after his disgrace Coke offered his daughter in marriage to Sir John Villiers, brother of the duke of Buckingham, the royal favorite. She was only 14 years of age, but was a rich heiress, as the estate of her mother, Lady Hatton, was entailed upon her, and she also had an expectancy from her father's immense wealth. The match had been sought by Villiers, who was poor, and had been rejected by Coke while chief justice. He determined on availing himself of it now for the purpose of recovering from his disgrace and humbling Bacon, who was now his open enemy. Lady Hatton, who was not on good terms with her husband, and had not been consulted, refused consent, and carried off her daughter to a place of concealment. Coke, having ascertained where they had fled, pursued, broke open the house, and took his daughter away. The mother appealed to the privy council. Bacon, who had been appointed lord keeper, warmly supported her, and proceedings were instituted in the star chamber against Coke. The king, however, who was then in Scotland, sharply reproved the lord keeper, and on his return the parties were so far reconciled that the marriage took place. Coke was restored to his place in the privy council (1617), but received no other appointment, except temporarily as one of the commissioners of the treasury while the office of lord treasurer was vacant. Bacon, on the other hand, entirely recovered a good understanding with the king,

and was shortly after made lord chancellor. The lord treasurer's office, which Coke expected to have had, was finally given to Montague, who had succeeded him as chief justice; and instead of his being restored to the chief justiceship, that place was filled by an obscure lawyer.—After his removal from office Coke did not intermit his legal pursuits. The 12th and 13th parts of his reports were prepared, though not published, as they contained the obnoxious opinions he had expressed upon proclamations, the court of high commission, and some other matters. He had also commenced his great work, the "Commentary on Littleton." Utterly destitute of orderly arrangement, this work is exuberant in legal learning and curious illustrations of English customs; vigorous in style, and interesting even to non-professional readers by the quaint and amusing analogies with which the gravest discussions are interspersed. The commentary is written in English, for which he deemed it necessary to make an apology in the preface. The reports, that is, the 11 parts which had then appeared, were printed in Norman French; the 12th and 13th parts were not published till 1654, having been translated into English, as were subsequently the other parts. The reports had one peculiarity which has never been adventured upon by any other author, viz.: that they represent many questions to have been resolved which in fact did not arise in the cause, or which were not at all events decided; and these he disposes of according to his own judgment, with abundant citations of authorities. Yet such was the respect entertained for his opinion, that these resolutions were always regarded as of equal weight with the opinions of the judges actually expressed.—The closing period of the life of Coke was brilliant and eventful. He was a member of parliament in 1621, and when the motion for a supply was made, secured a reference of the subjects of supply and grievances to a committee of the whole house. His first measure was a report upon the illegal grants of monopolies to Sir Giles Mompesson and Sir Edward Villiers, which report was agreed to, and sent to the upper house for concurrence. Consentaneously with this, an investigation of judicial abuses was instituted, which was aimed at Bacon; and although Coke declined acting as chairman of the committee, yet he directed all the proceedings, prepared the charges, and prescribed the mode of prosecution. Coke was to have been the manager of the prosecution before the house of lords; but Bacon shrank from the contest, and by a plea of guilty sought to shelter himself from his revengeful adversary under the sympathy of the lords and the dispensing power of the crown. Coke followed up his success by carrying through the house an address against the proposed match of Prince Charles with the infanta of Spain. This called forth a threatening response from the king, in which he mentioned Sir Edward Coke by name as particularly obnoxious to censure. Finally, in a letter to the speaker, the king intimated his intention "to punish any man's misdemeanor in parliament, as well during the sitting as after." Coke immediately moved a protestation for the privileges of the house, which having been reported by a committee, setting forth the right of every member of the house to freedom of speech, and the "like freedom from all impeachment, imprisonment, and molestation," on account of anything said or done in parliament, it was carried and entered on the journals of the house. The king immediately prorogued parliament, sent for the journals, and with his own hand tore out the offensive protestation. This was followed by a dissolution, and the arrest of Coke, Philips, Pym, and other leaders of the commons. The ex-chief justice was confined in the tower, but after some months' imprisonment was set at liberty, upon the intercession of Prince Charles; his name was however stricken out of the list of privy councillors. He was returned again as member of parliament on the accession of Charles I. (1625), and obtained the appointment of a committee on expenditures, which was proceeding so vigorously that the king suddenly dissolved parliament. An attempt was made to keep him out of the next parliament by appointing him sheriff of the county of Norfolk; nevertheless, he was returned as a member, but the parliament was dissolved before his right to a seat was settled. In 1628 he was again elected, and he proceeded at once to attack the recent illegal measures of the king. The first was commitments by order of the privy council, without specifying the cause in the warrant; and he carried through two resolutions, which constituted the basis of the famous habeas corpus act, passed many years after, in the 31st of Charles II. (1679). He then framed the famous petition of right, which enumerated the prominent grievances of the nation from the abuse of prerogative, and declared them all to be contrary to the laws and customs of the realm. This was carried through the house in spite of all the subterfuges of the king, and finally passed by the lords after a fruitless attempt to nullify the bill by a clause which was rejected by the commons; and after a treacherous attempt by the king to cheat the house by an evasive form of assent, he was finally compelled to approve the bill and it became a law. In every step of this arduous contest, Coke, now in his 76th year, rendered important service by his sagacity and firmness. It was his last appearance in public; though he survived six years, he lived in retirement. During this time he prepared a new edition of the commentary on Littleton, and wrote the second, third, and fourth Institutes. In 1633, when he was on his deathbed, his house was searched by order of the king for seditious papers, and all his manuscripts were carried off. He died two days afterward, in his 82d year. It is said that, except a slight attack of the gout, he was never sick until his 80th year.

COKE, Thomas, the first bishop of the Methodist Episcopal church, born at Brecon, South Wales, Sept. 9, 1747, died at sea, May 2, 1814. At the age of 16 he was sent to Oxford, and the succeeding year entered as gentleman commoner at Jesus college in that university. After graduating he returned to Brecon, of which place he was elected mayor at the age of 25. Meanwhile he pursued his studies, and in 1775 received the degree of D. C. L. Soon afterward he entered the ministry of the established church, and obtained a curacy at South Petherton. His preaching was thought too evangelical, and he was finally excluded from the pulpit. Sympathizing strongly with the Methodists, he sought an interview with Wesley, which resulted in his joining the Wesleyan society, and being appointed to London, where his zeal and talents soon brought him into notice. He rendered valuable assistance to Wesley in procuring what was called the deed of declaration, which provided for the settlement of the Methodist chapels in the connection, and restricted the conference to 100 of the preachers, and their successors. So fully had he gained the confidence of Wesley, that he was appointed president of the Irish conference in 1782. The American revolution having resulted in dissolving not only the political but the ecclesiastical relation between England and the former colonies, Wesley in 1784 ordained Coke as bishop of the Methodist church in America. In the same year he reached New York, and sought an interview with Francis Asbury, to whom he communicated the object of his mission. The authority of Coke was fully recognized, and he ordained Asbury as bishop, and both were duly accredited as the joint superintendents of the church in America. In company with Asbury he travelled through the different conferences until June, 1785, when he returned to England, and visited Wales, Scotland, and Ireland. Subsequently he went again to America, and attended the conferences throughout the entire connection. Thenceforth he devoted himself to missionary work. The first mission which he established was among the blacks in the West Indies, in 1786, whence, after visiting the several islands, he went to South Carolina, travelled through the states, and embarked for England in 1787. Soon after the session of the English conference, he went with Wesley to the Channel isles, and having spent some time there returned to England. The conference having appointed three missionaries for the West Indies, Coke accompanied them in 1788; and having passed through the islands he sailed for the continent, and arrived at Charleston in 1789. After visiting all the conferences, and with Asbury making provision for the wants of the churches under their care, he returned to England. Again in 1790 we find him among the West India islands, whence he proceeded to the continent and made the round of the conferences. While in Virginia he heard of the death of Wesley, and resolved on returning immediately to England, where he was chosen secretary of the conference. The revolution in France opening a field for Protestant missionaries, he set out for that country; but as he could not obtain a congregation in Paris, he returned to England, and devoted his time to soliciting aid for missions, and to preparing with Mr. Moore, who, with himself and Dr. Whitehead, had been designated by Wesley as his biographers, a life of that distinguished man. The conference this year engaged him to make a commentary on the Scriptures, and he made preparation for entering upon that work, which he prosecuted at intervals during another visit to the West Indies and the United States, ending in 1793. With a view of settling some difficulties which had arisen in the West Indies, he visited Holland; and on his return in 1794, he devoted himself to his commentary and to soliciting subscriptions for his missions. In 1795 he projected a mission among the Foolahs in Africa, and sent out a company of mechanics, but it proved a failure. In 1796 he again embarked for America, where he continued fulfilling his duties as bishop till 1797, when he went to Scotland and thence to Ireland. After the session of the English conference he again turned his course to America, where he arrived plundered of everything but his books, the vessel having been taken by a privateer. Again in England in 1798, he devised a plan of domestic missions for Ireland, and also established a mission in Wales. Before leaving once more for America, he published parts of his commentary, comprising the Old Testament; the remainder was not completed till 1807. The years 1802–'3 were mostly occupied in this work, so that he did not make his ninth and last visit to America till 1803. When his labors here were finished, he returned, and established a mission in Gibraltar. From this time till 1808 he was engaged in travelling in aid of the missionary cause. Meanwhile he had finished his commentary, made preparations for a history of the West Indies and a history of the Bible, and had compiled a system of philosophy. Through his influence a mission was established in 1811 at Sierra Leone, and several missionaries were sent out. In 1813 he opened a correspondence with the Rev. Claudius Buchanan in regard to India, which resulted in a determination on his part to establish a mission on the island of Ceylon. At the conference this year five preachers volunteered to go with him; and such was his zeal that when the conference hesitated on account of the expense that would be incurred, he furnished £6,000 from his own private fortune. The missionaries embarked Dec. 30, and after having been out four months, Coke was found dead in his cabin, and was buried at sea. He was a voluminous writer. Besides numerous addresses and letters to the church, he published "Life of John Wesley," written in conjunction with Henry Moore

(1792); "A Commentary on the Holy Scriptures" (6 vols. 4to, 1807); "History of the West Indies" (3 vols., 1808–'11); "History of the Bible," and "Defence of the Doctrine of Justification by Faith and the Witness of the Holy Spirit."

COKE, Thomas William, earl of Leicester of Holkham, an English agriculturist, born May 4, 1752, died June 30, 1842. He was regarded, after the death of the duke of Bedford, as the first agriculturist in the kingdom. His estate of Holkham, in Norfolk, the rental of which he raised in the period of some 60 years that it was in his possession from £2,000 to above £20,000, was the pride of the county. His annual sheep shearing, at which he entertained hundreds of guests for several days, was reckoned the greatest agricultural festival in the world. His methods of cultivation were based upon scientific principles. He introduced choice breeds of cattle and the rotation of crops, and recommended the extensive planting of turnips. He represented the county of Norfolk in parliament, with a brief interval, from 1776 to 1832. An intense hatred of toryism constituted almost the whole of his political system, but he spoke little except when agricultural measures were before the house. In 1837 he was created earl of Leicester of Holkham. Sixty years before he had been twice offered a peerage; but he refused to accept anything but the earldom of Leicester, which had been held by his maternal great-uncle, whose estates he inherited, but not his title, which had meantime been given to another person. As this earldom was still held by Marquis Townshend, the title was varied for Mr. Coke by the addition of the name of his own estate.

COLAPOOR, or **Kolapoor. I.** A rajahship of Bombay presidency, British India, bounded N. and N. E. by Sattara, E. and S. by Belgaum, and W. by the Ghauts; area, 3,445 sq. m.; pop., including dependencies, about 500,000, mostly Mahrattas and Ramooses. The latter are a predatory, warlike tribe, resembling the Bheels, to whom, however, they are superior in intelligence. The people of certain maritime towns formerly subject to the rajah were much addicted to piracy, and in 1765 the Bombay government undertook to check them by sending an expedition against Colapoor. The fort of Malwan was captured, but the evil was not entirely suppressed till 1812. The country was afterward repeatedly occupied by British troops. In 1842 the government was confided to an agent of the British, against whom a general rebellion was aroused in 1844. The rising was put down, and the control of the state was thenceforth exercised directly by the British in the name of the rajah. **II.** The capital of the rajahship, situated in a secluded valley, little visited by Europeans, 185 m. S. S. E. of Bombay, and 130 m. S. of Poonah. It is fortified, though with little strength. The first decided outbreak in the Bombay presidency, during the rebellion of 1857, occurred here.

COLBERG, or **Kolberg,** a town of Pomerania, Prussia, in the circle and 24 m. W. of the city of Köslin, on the Persante, near its mouth in the Baltic; pop. in 1872, 13,130, exclusive of a garrison of about 1,600 men. It possesses a harbor called Münde, and contains a cathedral, an ancient ducal castle, now used for a charitable institution, several churches, hospitals, factories, salt works, distilleries, extensive salmon and lamprey fisheries, and considerable export trade. The town house and aqueduct are worthy of note. Colberg has a gymnasium and a house of correction, and is noted for its sea bathing. It is memorable for the sieges it stood in 1760 and again in 1761 against the Russians, to whom it capitulated in the latter year, and in 1806–'7 against the French, when it was successfully defended by Gneisenau. In February, 1873, the government proposed to dismantle the fortress.

COLBERT, a N. W. county of Alabama, recently formed from a portion of Franklin county, bounded N. by the Tennessee river, and W. by Mississippi; pop. in 1870, 12,537, of whom 4,639 were colored. It is intersected by Big Bear creek and other affluents of the Tennessee. The Memphis and Charleston railroad passes through it. The chief productions in 1870 were 12,682 bushels of wheat, 291,402 of Indian corn, 14,347 of oats, and 3,986 bales of cotton. There were 1,190 horses, 799 mules and asses, 1,623 milch cows, 2,699 other cattle, 2,735 sheep, and 8,267 swine. Capital, Tuscumbia.

COLBERT. I. Jean Baptiste, marquis de Seignelay, a French statesman, born at Rheims, Aug. 29, 1619, died in Paris, Sept. 6, 1683. The son of a merchant, he obtained employment as a clerk in an Italian banking house at Paris, at the recommendation of Mazarin, who soon after intrusted him with the management of his private affairs. On his deathbed the cardinal said to Louis XIV.: "Sire, I am indebted to you for all that I possess; but I think I am requiting all your majesty's favors by giving you Colbert." At once admitted to the king's confidence, he began by exposing the maladministration of Fouquet, whom he succeeded in 1661 as comptroller general. Colbert's administration became a blessing to France. Order was restored in the finances, the revenue was increased, and the treasury was enabled to furnish the means for foreign wars as well as for internal improvements. The public debt was greatly reduced, and the manufacturing interest was revived. Several large manufactories were established at the expense of the government, the most celebrated of which was that of the Gobelins. Land taxes were lessened and more justly assessed; the excise upon salt was reduced; highways and roads were kept in repair, and new ones established; the Atlantic was united to the Mediterranean by the canal of Languedoc, and water communications were extended through nearly all parts of France. He was appointed

minister of the navy in 1669, and the French fleet, which then consisted of but 50 ships, numbered in a few years 198 men-of-war. Colbert also encouraged literature, science, and art. He founded the academies of inscriptions and belles-lettres, of science, and of architecture, sculpture, and painting, and at Rome reëstablished the French school of painting. He founded the observatory and the *jardin des plantes;* increased the royal library and the collection of coins and medals; bestowed pensions on eminent artists and scholars; and enriched Paris with the garden of the Tuileries and the colonnade of the Louvre, and with many quays, bridges, boulevards, public buildings, triumphal arches, and monuments. He opposed the wars and follies of Louis XIV., and succeeded for many years in restraining him within the limits of reasonable ambition. But about 1670 his favor was on the wane, and the influence of Louvois, the minister of war, prevailed. Then commenced a series of European wars that partly exhausted the wealth and resources accumulated by Colbert. He continued however serving the government, but the reckless course which was now pursued impaired his usefulness. He had been so long engaged in public affairs that he was loath to retire, but he suffered much from the ingratitude of the king. During his last moments he gave vent to his feelings by saying: "If I had done for God what I have for that man (Louis XIV.), I would have more than deserved salvation, and I do not know now what will become of me." Thus died one of the greatest ministers of France. He was hated by his colleagues, perhaps by the king, and certainly by the people, who held him responsible for taxes which had been established notwithstanding his remonstrances, and for vexations of which he was not the author. To protect his funeral against the attacks of the mob, it took place at night, attended by a military escort. A monument was erected by his family in the church of St. Eustace; and his statue was placed in 1844 in the Palais Bourbon. Posterity has placed Colbert among the most eminent statesmen; and although his commercial policy has been the object of severe animadversion, it cannot be denied that it was perhaps the best adapted to his time and country. An edition of the *Lettres, instructions et mémoires de Colbert* was published at Paris in 1872. **II. Jean Baptiste,** marquis de Seignelay, son of the preceding, born in Paris in 1651, died Nov. 3, 1690. He succeeded his father as minister of the navy, and raised the French navy to its highest power by his capacity and energy. In 1684 he led in person the maritime expedition against Genoa.

COLBURN, Warren, an American mathematician, born at Dedham, Mass., March 1, 1793, died at Lowell, Sept. 15, 1833. He was the eldest son of a large family. His parents were poor, and during his childhood made frequent removals to different manufacturing villages, where Warren as well as some of the other children found employment in the factories. He early manifested a remarkable taste for mathematics, and having acquired the trade of a machinist, he entered Harvard college in 1816. He graduated in 1820, and soon afterward opened a select school in Boston. In the autumn of 1821 the first edition of his "First Lessons in Mental Arithmetic" was issued. While in college the necessity of such a work had been forced upon his mind, and its plan digested. He was accustomed to say that "the pupils who were under his tuition made his arithmetic for him;" that the questions they asked, and the necessary answers and explanations which he gave in reply, were embodied in that book. No other elementary work on arithmetic ever had such a sale. It has been translated into most of the languages of Europe, and into several of those of India. After teaching nearly three years, he accepted the situation of superintendent of the Boston manufacturing company at Waltham, in April, 1823; and in August, 1824, he was appointed superintendent of the Merrimack manufacturing company at Lowell. Here he projected a system of lectures of an instructive character, presenting commerce and useful subjects in such a way as to gain attention. In the autumn of 1825 he commenced a course of lectures on the natural history of animals. This he followed in subsequent years with lectures on light, the eye, the seasons, electricity, hydraulics, astronomy, &c. His "Sequel" had been published just before he left Waltham. In 1828 he published his "Algebra." In May, 1827, he was elected a fellow of the American academy of arts and sciences. He was also for a number of years one of the examining committee on mathematics in Harvard college, and some time superintendent of schools at Lowell.

COLBURN, Zerah, an arithmetical prodigy, born at Cabot, Vt., Sept. 1, 1804, died March 2, 1840. In his 6th year he began to give evidence of those extraordinary powers of computation which afterward excited the wonder of the learned and curious in the United States and Europe. His father decided to exhibit them in public, and accordingly left Vermont with Zerah in the winter of 1810–'11. Passing through Hanover, N. H., Dr. Wheelock, then president of Dartmouth college, offered to take upon himself the whole care and expense of his education, but his father rejected the offer. At Boston the performances of the boy excited much attention. He was visited by the professors of Harvard college, and by eminent men in all professions, and the newspapers were filled with articles concerning his wonderful powers of computation. Questions in multiplication of four and five places of figures, reduction, rule of three, practice, involution, evolution, compound fractions, and the obtaining of factors even of large numbers, were answered with accuracy and with a rapidity to which the most experienced mathematicians could not at-

tain. At this time he was unable to give any account of the mental processes by which these results were reached; but a few years later he could explain them satisfactorily, and from these explanations it appeared that his processes did not differ materially from those ordinarily adopted in mental computation. Among the questions proposed to him were the following: How many days and hours in 1,811 years? His answer, given in 20 seconds, was 661,015 days, 15,864,360 hours. How many seconds in 11 years? The answer, given in four seconds, was 346,896,000. When 8 or 9 years of age, he gave answers with a delay of but a few seconds to such questions as these: What is the square of 999,999? Multiply the square twice by 49 and once by 25. (The answer requires 17 figures.) What are the factors of 4,294,967,297? ($=2^{32}+1$). The French mathematicians had announced this as a prime number. Colburn immediately gave $641 \times 6{,}700{,}417$. What are the factors of 247,483? He replied, "941 and 263, which are the only factors." The rapidity of his mental processes and the power of his memory must have been at this time almost inconceivable. After leaving Boston, Mr. Colburn exhibited his son for money throughout the middle and part of the southern states, and in January, 1812, sailed with him for England. After travelling over England, Scotland, and Ireland, they spent 18 months in Paris. Here young Colburn was placed in the *lycée Napoléon*, but was soon removed by his father, who at length, in 1816, returned to England in the deepest penury. The earl of Bristol soon became interested in the boy, and placed him in Westminster school, where he remained till 1819. In consequence of his father's refusal to comply with certain arrangements proposed by the earl, he was removed from Westminster, and Mr. Colburn now proposed to his son that he should qualify himself to become an actor. Accordingly, he studied for this profession, and was for a few months under the tuition of Charles Kemble. His first appearance, however, satisfied both his instructor and himself that he was not adapted for the stage, and accordingly he accepted a situation as assistant in a school, and soon afterward commenced a school of his own. To this he added the performing of some astronomical calculations for Dr. Thomas Young, then secretary of the board of longitude. In 1824, on the death of his father, he was enabled by the earl of Bristol and other friends to return to America. He went to Fairfield, N. Y., as assistant teacher of an academy; but not being pleased with his situation, he removed in March following to Burlington, Vt., where he taught French, pursuing his studies at the same time in the university. Toward the end of 1825 he connected himself with the Methodist church, and after nine years of service as an itinerant preacher, he settled in Norwich, Vt., in 1835, where he was soon after appointed professor of languages in Norwich university. In 1833 he published his autobiography. From this it appears that his faculty of computation left him about the time he reached the age of manhood; and aside from his early talent for calculation, he gave no evidence of remarkable abilities.

COLBY, Thomas, an English engineer, born at Rochester, Sept. 1, 1784, died in Liverpool, Oct. 9, 1852. He was educated at the royal military academy at Woolwich, and received his first commission as second lieutenant of engineers when 17 years old. The next year he became chief personal assistant of Captain Mudge, then superintendent of the ordnance survey. During the four following years he passed the summers in making observations at various prominent points, and the winters in preparing the results for publication and superintending the engraving of the ordnance maps. He became identified with the great trigonometrical survey of England, and upon the publication of the third volume of the records his name appeared associated with that of Col. Mudge upon the title page. In 1807 he was raised to the rank of captain. In 1813 it was determined to extend the meridian line into Scotland, and Capt. Colby was placed in charge of the work. In 1817 he accompanied Biot, a scientific agent of the French government, on his trip to Shetland, and afterward assisted in connecting the French with the English triangulation by observations across the straits of Dover. Upon the death of Gen. Mudge in 1820, Colby was appointed his successor as superintendent of the survey and in the board of longitude, was elected a fellow of the royal society, and promoted to the rank of major, and soon after to that of lieutenant colonel. Having undertaken a thorough survey of Ireland, he received the sanction of the duke of Wellington for raising and training three companies of sappers and miners to aid in the work. After a series of experiments on the heating and cooling of metallic rods, he succeeded in so uniting a bar of brass and iron that its extremities always remained the same distance apart whatever the temperature. With this "compensation bar" he measured a base line of eight miles on the south side of Lough Foyle; and such was the exactitude obtained that the same apparatus has since been used in the remeasurement of the English bases, in measuring a base at the Cape of Good Hope, and also those required for the great arc of the meridian in India. Col. Colby continued his superintendence of the survey till his promotion in 1846 to the grade of major general, when by the regulations of the service his active connection with it ended. He had brought English maps to an excellence not before attained, marking the seconds of latitude and longitude on the margin, and introducing into them geological facts and features.

COLCHESTER, a municipal and parliamentary borough, market town, and river port of Essex, England, on the river Colne, and the Great

Eastern railway, 51 m. N. E. of London; pop. in 1871, 26,361. It is built on a hill close to the river, and has three bridges, one of which is of cast iron. Among the public buildings are eight churches, one built before the time of Edward II. and another mentioned in the Domesday Book, nine dissenting chapels, a

Abbey Gate.

library, and the ruins of an old castle, of a Benedictine abbey founded under Henry I., and of St. Botolph's priory, an interesting structure of the 12th century. There are many charitable and other schools, a mechanics' institute, a literary and scientific association with a museum, a botanical and horticultural society, several almshouses, hospitals, and other charities, and a theatre. The woollen

St. Botolph's Priory.

manufacture, formerly important, was subsequently superseded by that of silk, which employs 300 or 400 hands. Some velvet is also manufactured. The most important branch of industry is the oyster fishery, for which the town has long been noted. There are iron and brass founderies, machine shops, rope, sail, and carriage factories, breweries, vinegar works, &c. Colchester was made a bonding port in 1808, but the custom house and warehouses are at Hythe, one of its suburbs, situated a short distance below, at the head of navigation on the Colne. The foreign commerce is inconsiderable, but a large coasting trade is carried on with London and the northern counties.— Colchester is supposed to be the Camulodunum of the Romans, and there is probably no town in England richer in remains of that people. Coins, vases, urns, lamps of bronze and pottery, rings, bracelets, tessellated pavements, and various other antiquities, have been found near it in great profusion. The Saxons, uniting the Latin *castra* with the name of the river on which it stands, called it Colne Ceaster. It was fortified by Edward the Elder, and at the time of the Domesday survey was a place of no small note. It was taken and occupied by the royalists in 1648 after a memorable siege, and was soon after blockaded by the parliamentarians, to whom the garrison surrendered after 11 weeks' resistance.

COLCHESTER, a county of Nova Scotia, bounded N. by Northumberland strait, and S. and S. W. by Mines basin, Cobequid bay, and the Shubenacadie river; area, 1,300 sq. m.; pop. in 1871, 23,331. It is intersected by numerous rivers, and traversed by the Cobequid range of hills. The soil is of variable fertility. Among the minerals are coal, gypsum, and limestone. The principal occupations are agriculture, lumbering, and ship building. The county was originally settled by the French, who on their expulsion were replaced by emigrants from the north of Ireland and Massachusetts. Capital, Truro.

COLCHESTER, Lord. See Abbot, Charles.

COLCHICUM (from Colchis, a country where it abounded), a common name of the *colchicum autumnale* (Linn.), or meadow saffron, a perennial bulbous-rooted plant, growing naturally in the temperate climates of Europe, and cultivated for its medicinal properties. It prefers wet meadows, which it often covers with its bright, purple, crocus-like blossoms. The bulb or corm resembles that of a tulip, and feeds the growing plant, being exhausted and replaced every year. Colchicum closely resembles the autumn crocus, from which it is distinguished by having six stamens instead of three, and three styles instead of one. The corm, seeds, and flowers all possess the medicinal properties of the plant, which depend upon the alkaloid, colchicia. From the corm and seeds are prepared wines, extracts, and tinctures.—Colchicum is employed in the treatment of gout and rheumatism, and allied affections. The preparation for gout, celebrated under the name of *eau médicinale d'Husson*, is said to be a vinous infusion of colchicum It materially lessens the duration of the paroxysms of gout, but is apt when too freely used to depress the system and thereby induce a more speedy recurrence of the disease. It

has been shown to increase not only the water, but the organic solid constituents of the urine; this increase, however, is not due to uric acid, as might perhaps be supposed from its action in gout. It has a marked sedative action upon the heart, stimulates the secretions, and is apt to excite nausea and catharsis. While there is no doubt that advantage may be obtained from the administration of colchicum in certain forms or conditions of gout, rheumatic gout, and rheumatism, yet grave disadvantages are apt to result if it is given injudiciously. It should never be administered in the asthenic forms of gout or rheumatism; the doses should always be small at first, and gradually increased; it should not be allowed to excite continued nausea, or vomiting or purging; it should not be given for more than a week or ten days continuously, as its effects are apt to accumulate in the system; it should rarely or never be given to aged people or young children. In fine, its appropriate use is limited to the sthenic forms of gout and acute forms of rheumatism that occasionally occur in people of robust constitution, who are in the prime of life. It should be remembered that where neuralgia occurs in persons who come of a gouty or rheumatic race, it sometimes yields to a judicious course of colchicum. The dose of the acetic extract of colchicum is from 1 to 2 grains three times a day; of the wine of the root from 10 to 20 drops, and of the wine of the seeds 20 to 30 drops, three times a day. The tincture of the seeds may be given in the dose of half a teaspoonful to a teaspoonful.

Colchicum.

COLCHIS (modern Mingrelia and part of Imerethia), an ancient country of Asia, at the E. extremity of the Euxine, bounded N. by the Caucasus, E. and S. E. by Iberia and the Moschian mountains, S. by Armenia, S. W. by Pontus, and W. by the Euxine. Colchis was celebrated in Greek mythology as the destination of the Argonauts, and as the country of Medea and the golden fleece. Its early history is involved in obscurity. The early Greek writers speak of it only under the name of Æa, the seat of King Æetes. Cyrus or his immediate successor seems to have annexed it to the Persian empire; but its inhabitants soon recovered their liberty, and erected their territory into an independent state. During the Mithridatic war it was tributary to the kingdom of Pontus. On the overthrow of Mithridates it was annexed by the Romans; and after the conclusion of the civil wars it was incorporated with Pontus, and subjected to the rule of a proconsul. Under the later emperors it was known as Lazica, from Lazi, a predominant tribe. In A. D. 572 the Colchians rose in rebellion, and joined the Persians against the Byzantine empire. Colchis, according to Strabo, abounded in fruit of every kind, and in material for ship building. It was inhabited by a number of tribes, whose dark complexion, crispy hair, language, and customs indicated, in the opinion of Herodotus, their Egyptian origin. They were famous for the manufacture of linen. Their chief town was Dioscurias. The Phasis (now the Rion) is the celebrated river of this country.

COLD. See CATARRH.

COLDEN. I. Cadwallader, a physician and statesman, born in Dunse, Scotland, Feb. 17, 1688, died on Long Island, N. Y., Sept. 28, 1776. He studied at Edinburgh, and at the age of 20 emigrated to America, and practised as a physician for some years in Pennsylvania. He then visited England, but returned to Pennsylvania in 1716, and in 1718, at the solicitation of Gov. Hunter, settled in New York. The next year he was appointed the first surveyor general of the colony, became in 1720 a member of the king's council of the province, and in 1761 was appointed lieutenant governor of New York, and held the commission during the remainder of his life. He was repeatedly placed at the head of the government by vacancies in the governorship. He published works upon a variety of subjects, medicine, philosophy, and history; his "History of the Five Indian Nations of Canada, depending on New York" (New York, 1727; 3d ed., 2 vols., London, 1755) is especially worthy of mention; but his favorite pursuit was botany, and he sent to Linnæus several hundred American plants, of which that botanist published descriptions. **II. Cadwallader David,** grandson of the preceding, born near Flushing, L. I., April 4, 1769, died at Jersey City, Feb. 7, 1834. He commenced the practice of law in New York in January, 1791, removed his office for a time to Poughkeepsie, and in 1796 resumed his station at the New York bar, where he received the appointment of district attorney, and soon became eminent in the profession, which he practised for several years, intermitted only by a voyage to France for the benefit of his health. In 1812 he was colonel of a regiment of volunteers; in 1818 was elected a member of the house of assembly; in the same year

succeeded De Witt Clinton as mayor of New York city; in 1822 was elected to congress, and in 1824 to the senate of his own state, from which he withdrew in 1827. He was an active promoter of internal improvements, his name being especially connected with the completion of the Erie and Morris canals. Public education and the reformation of juvenile offenders were also subjects to which he devoted much attention. For many years he was one of the governors of the New York hospital. He wrote a biography of Robert Fulton (1817) and "Memoir of the Celebration of the Opening of the New York Canals" (1825).

COLD HARBOR, Battles of. See CHICKAHOMINY.

COLDSTREAM, a town of Berwickshire, Scotland, 12 m. S. W. of Berwick; pop. about 2,200. It is situated on the left bank of the Tweed, here spanned by a handsome bridge. Besides the parish church, there are several places of worship, and a number of schools and libraries. The principal trade is in agricultural products and in cattle. Adjoining the town is the celebrated ford of the Tweed which was repeatedly crossed by the invading armies of both Scotland and England. Monk raised a corps here in 1659–'60, which was at first known as Monk's regiment, but subsequently it was included, under the name of Coldstream guards, in the brigade which parliament allowed to Charles II.; it retains this designation as a regiment in the foot guards or household brigade, and is one of the oldest corps in the British army.

COLDWATER, a city, the capital of Branch co., Michigan, on the Coldwater river and the Michigan Southern railroad, 103 m. W. S. W. of Detroit; pop. in 1870, 4,381. It is the commercial centre of a fertile country. The river affords good water power, which has been improved. There are six or eight churches, two banks, two weekly newspapers, and a monthly periodical. In 1871 there were 18 schools, of which one was a high school, with 20 teachers and 1,128 pupils.

COLE, a central county of Missouri, bounded N. E. by the Missouri river, S. E. by the Osage, which joins the Missouri at the E. extremity of the county, and drained by Moreau creek; area, 410 sq. m.; pop. in 1870, 10,292, of whom 1,251 were colored. It has an undulating surface, and a generally fertile soil, though in some places the land is too rocky for cultivation. Timber, limestone, and buhrstone are abundant. The Pacific railroad of Missouri passes through it. The chief productions in 1870 were 115,299 bushels of wheat, 165,550 of Indian corn, 60,668 of oats, 24,599 of potatoes, and 2,798 tons of hay. There were 1,570 horses, 1,520 milch cows, 2,496 other cattle, 4,701 sheep, and 8,402 swine; 2 manufactories of boots and shoes, 1 of carriages and wagons, 1 of furniture, 1 of saddlery and harness, 3 flour mills, 2 saw mills, and 3 breweries. Capital, Jefferson City, which is also the capital of the state.

COLE, Thomas, an American painter, born at Bolton-le-Moor, Lancashire, England, Feb. 1, 1801, died at Catskill, N. Y., Feb. 11, 1848. His father, a small woollen manufacturer, after repeated reverses in business, emigrated to America in 1819, and established himself in Steubenville, Ohio. The artist's childhood was unmarked by striking incidents, but the direction of his tastes could be seen in his employment as a designer in a print factory, and in making woodcuts for printers. A fine organization and great fondness for poetry and scenery were his chief characteristics. Two years were spent at Steubenville in the employment of his father, who kept a small shop, when a portrait painter named Stein passed through the town in the pursuit of his vocation, and Cole, fascinated by the sight of his canvas and colors, at once determined to become a painter. With rude materials, mostly prepared by himself, he attempted landscapes and miscellaneous subjects, and finally portraits. In February, 1822, he went on foot to Clairsville, where he proposed to establish himself as a portrait painter. The western states did not then afford a promising field for artists, and both at Clairsville and Zanesville, which he subsequently visited, he not only failed to meet with any encouragement, but when he rejoined his family in the spring at Pittsburgh he was in debt for the means of support during his absence. Undiscouraged by reverses, he spent the spring and summer of 1823 in making careful studies from nature in the vicinity of Pittsburgh, and the autumn saw him established in Philadelphia as a landscape painter. The ensuing winter was one of great privation. He painted small landscapes and comic pieces, and was often glad to find regular employment in ornamenting chairs, brushes, and japanned ware. His powers however were rapidly developing, and in the works of this period may be seen the germ of that rich and harmonious style for which he was afterward distinguished. In the spring of 1825 he removed to New York, where his family were now established, and fixed his studio in the garret of his father's house in Greenwich street. The scenery of the Hudson called out all his artistic enthusiasm, and during a visit to the Catskills in the autumn of this year he painted several landscapes, which were exhibited on his return to the city. These pictures attracted the attention and praise of Durand, Dunlap, and Trumbull, and "from that time," says Bryant in his funeral oration on Cole, "he had a fixed reputation, and was numbered among the men of whom our country has reason to be proud." The next four years found Cole in the enjoyment of great prosperity; commissions flowed in upon him from all quarters; and visits to the White mountains, the Catskills, and Niagara afforded varied and striking studies. But in the midst of a career from which few artists would have cared to deviate, Cole felt that the literal re-

production of natural scenery, however profitable it might be, could not satisfy him; and he determined to enter the higher sphere of imaginative composition. The fruit of this determination was witnessed in his pictures of the "Garden of Eden" and the "Expulsion," exhibited in 1828. The merit of these works was admitted, but they failed to satisfy the public taste so completely as his simple landscapes. In June, 1829, Cole sailed for Europe, and for two years painted in London, where he contributed to several of the annual exhibitions; but from ignorance of the peculiar features of American scenery, or the injustice of hanging committees, his pictures were either regarded as exaggerations of nature, or were so disadvantageously placed that they attracted less attention than their merits deserved. In May, 1831, he visited Florence, and made careful studies in the chief galleries. In the succeeding February he visited Rome, and returning to Florence in July, worked with an assiduity which surprised himself, finishing more pictures in three months than he had done in double that time before. Among these were views on the Arno and in the vicinity of Rome and Naples. The influence of Italian scenery and of his studies of old Italian art had meanwhile wrought a change in his style, and the public were disappointed with these works upon their arrival in America, complaining that the artist had lost his first freshness and originality, and that his Italian landscapes were overcharged copies from the old masters. In November, 1832, he returned to New York, and during the ensuing year, while at Catskill, he received from Mr. Luman Reed of New York an order to fill an entire room of his house with pictures. The magnitude of the undertaking required several years of undivided labor, the most of which was devoted to the "Course of Empire," a series of five pictures, in which are presented, to use his own words, "an illustration of the history of the human race, as well as an epitome of man, showing the natural changes of landscape, and those effected by man in his progress from barbarism to civilization, to luxury, to the vicious state, or state of destruction, and to the state of ruin or desolation." The series has been called "a great epic poem." Mr. Reed died before the completion of the work, and at the distribution of his estate it was purchased by the New York gallery of fine arts, and is now in the gallery of the New York historical society. For the next few years Cole was engaged upon works of a similar class, chief among which were the "Departure" and the "Return," the "Dream of Arcadia," and the "Voyage of Life." The last, an allegorical series of four pictures, representing childhood, youth, manhood, and old age, are among the most popular of his works, and through the engravings by Smillie are most extensively known. They are now owned by J. Taylor Johnston of New York. In November, 1836, he married Miss Maria Bartow. The autumn of 1841 found him again in Rome, where he executed a duplicate of his "Voyage of Life," which elicited the praise of Thorwaldsen, who visited his studio repeatedly to see it. In the succeeding spring he travelled over many parts of Sicily, and returned to New York in the summer. An exhibition of his works was opened in Boston and New York in the winter of 1843–'4, for which he painted a number of Sicilian views of great beauty, including a large picture of Mount Etna from Taormina, executed in five days; this is now in the Wadsworth gallery, Hartford, Conn., as are also the "View of the White Mountains" and the "View of Northwest Bay on Lake Winnipiseogee." The "Angel appearing to Shepherds" is in the Boston Athenæum. Thenceforth until his death he painted with industry, executing among other works the "Cross in the Wilderness," "L'Allegro" and "Il Penseroso," "Home in the Woods," the "Hunter's Return," the "Mountain Ford," &c. The "Cross and the World," a work in two parts, dictated by earnest religious conviction, he left unfinished. His life and genius were made the subject of a funeral oration by his friend William Cullen Bryant. In all the relations of life Cole's amiability and generosity were engagingly displayed, and to those who could sympathize with his enthusiastic and impressible nature, he especially endeared himself. His life was one of singular purity, and in the latter part of it he manifested a sincere and unostentatious piety. His poetic feeling frequently found expression in rhythmical forms, and his miscellaneous papers in prose and verse, few of which were ever made public, possess considerable literary merit.

COLE, Vicat. See supplement.

COLEBROOKE, Henry Thomas, an English orientalist, born in London, June 15, 1765, died there in March, 1837. He was the son of Sir George Colebrooke, who in 1769 was appointed chairman of the board of directors of the East India company. His early education was conducted by a private tutor. In 1782 he was appointed to a writership in the East India company, and in 1783 he arrived in Madras. He soon went to Calcutta, and was employed in the company's board of accounts. In 1786 he was appointed assistant collector of revenue in Tirhoot. In the mean time he had devoted much attention to the study of Sanskrit, but his interest in it does not seem to have been so much literary as scientific, his love of astronomy and mathematics leading him to desire to ascertain what the Hindoos knew in regard to these sciences. In 1789 he was transferred to Purneah, and in 1793 to Nattore. He had now become interested in the religion, philosophy, and laws of the Hindoos. In 1794 he presented to the Asiatic society his first paper, "On the Duties of a Faithful Hindoo Widow." At the same time his views on commerce and finance were far in advance of his age; and though a servant of the East India

company, he favored the withdrawal of its special privileges, and advocated free trade between India and England. Just after the death of Sir William Jones in 1794, Colebrooke was transferred from the financial to the judicial branch of the service. The code of laws compiled under the direction of Warren Hastings, and published in 1776, being very imperfect, at the solicitation of Sir William Jones the government had determined to have a more extensive and accurate compilation made. This was performed chiefly by a learned pundit, Jagannatha, and was to have been translated by Jones, but the task was committed to Colebrooke. The work was published under the title, "A Digest of Hindu Law on Contracts and Successions, with a Commentary by Jagannatha" (4 vols. 4to, Calcutta, 1797–'8). From that time until his death Colebrooke stands forth as the first of European Sanskrit scholars. While occupied with this work he had resided at Mirzapore, near Benares, the chief seat of Hindoo learning. In 1798 he was sent on a diplomatic mission to Nagpore, the capital of Berar; in 1801 he returned to Mirzapore, and shortly after was summoned to Calcutta, and appointed a member of the court of appeal. He was also appointed professor of Sanskrit in the college then recently established at Fort William, but he took no active part in teaching, acting rather as a director of the course of studies and as an examiner. In the same year appeared his essay on the Sanskrit and Prakrit languages, which showed that he was bringing within the range of his studies every part of Hindoo literature. In 1805 he became president of the court of appeal. During this interval from 1801 to 1805 he worked on the supplement to his "Digest of Laws," and at deciphering ancient inscriptions, assisted Roxburgh in the preparation of his "Flora Indica," wrote the first volume of his "Grammar of the Sanskrit Language," and prepared several essays. The first volume of his "Sanskrit Grammar" was published in 1805, and though it was never finished, it forms the best existing introduction to the study of the native grammarians. In the same year he published his famous essay "On the Vedas or Sacred Writings of the Hindus," which will always be regarded as a landmark in the history of the study of Sanskrit literature by Europeans. In 1806 he became president of the Asiatic society, and he contributed to its volumes essays "On the Sect of Jina," "On the Indian and Arabic Divisions of the Zodiac," and various others. The highest honor of a civilian in the service of the East India company, a seat in council, was conferred upon him in the same year. In 1810 he published translations of two important treatises on the Hindoo law of inheritance. In 1815, after having resided in India 33 years, he returned to England. The remainder of his life was devoted almost uninterruptedly to the prosecution and promotion of Sanskrit studies. In 1817 he published "Algebra, with Arithmetic and Mensuration, from the Sanskrit of Brahmagupta and Bhāskara," preceded by a dissertation on the state of the sciences as known to the Hindoos. In the following year he presented to the East India company his collection of MSS., one of the most valuable ever brought to Europe. Pecuniary matters compelled him to spend a year at the Cape of Good Hope, and on his return to England in 1822 he was elected president of the astronomical society, succeeding Sir William Herschel. He also exerted himself to found the royal Asiatic society, of which he declined the presidency, but became its most active member; and for several succeeding years he contributed to its volumes essays upon the philosophy of the Hindoos, the value of which is yet unimpaired. These were his last contributions to the study of oriental literature. Many of his works yet remain unpublished. A collection of his miscellaneous essays was published in London in 1837; a second edition appeared in 1858; and in 1872 a third, in 3 vols. 8vo, including a selection from his correspondence, and a biography by his son, Sir Edward Colebrooke.

COLEMAN, a W. county of Texas, watered by Pecan bayou, Jim Ned creek, and other affluents of the Colorado; area, 1,000 sq. m.; pop. in 1870, 347, of whom 7 were colored. The surface is broken and rocky, adapted to stock-raising. Timber is scarce, and the climate dry and salubrious. The chief productions in 1870 were 5,050 bushels of Indian corn, and 35 tons of hay. There were 14,198 cattle. Capital, Camp Colorado.

COLEMAN, William, an American journalist, born in Boston, Feb. 14, 1766, died in New York, July 13, 1829. He was educated for the bar, and commenced practice in Greenfield, Mass. During Shays's rebellion he took up arms against the insurgents. In 1794 he removed to New York, where for a short time he was a partner of Aaron Burr in the practice of law. Subsequently he was appointed reporter of the supreme court of the state of New York, a position which he lost after the defeat of the federal party in 1800. In 1801 Hamilton and other leading federalists conceived the idea of establishing a daily paper in the city of New York, and Coleman was selected to conduct it. The new organ, under the name of the "Evening Post," appeared Nov. 16, 1801, and for nearly 20 years Coleman remained its sole editor. His connection with it ceased only with his death. His attachment to federalist principles never wavered, and even after the party became extinct he continued to be its warm defender. He enjoyed the reputation of an able, honest, and fearless man.

COLENSO, John William, D. D., an English clergyman and colonial bishop, born in Cornwall, Jan. 24, 1814. He took his degree at St. John's college, Cambridge, with distinguished honor, in 1836, and became fellow of his college. In 1838 he became assistant master at

Harrow, in 1842 tutor of St. John's college, and in 1846 rector of Forncett St. Mary. In 1854 he was appointed bishop of Natal, S. Africa. He had previously published text books in arithmetic, algebra, and trigonometry, a volume of sermons, and an edition of the communion service, with selections from the writings of F. D. Maurice. In 1861 he published "The Epistle to the Romans, newly translated, and explained from a Missionary Point of View," and in 1862 "The Pentateuch and Book of Joshua, Critically Examined." This last work, in which he called in question many of the statements contained in those books, excited much animadversion, and was formally condemned by the convocation of the province of Canterbury, and he was declared by the bishop of Cape Town to be deposed from the office of bishop. An appeal to the privy council was taken upon the ground that the crown had no right to create a bishop in any colony where there was an independent legislature, and that therefore there was in law no bishop either of Cape Town or Natal. In England he found many sympathizers, and previous to his return to Natal in 1865 a public meeting was held, and he received a testimonial of £3,300. In 1866 he published a volume entitled "Natal Sermons," and several papers justifying his course in the controversy. In January, 1869, the Rev. William Kenneth Macrorie was consecrated bishop of Maritzburg in Natal, it being held that the see was duly vacated by his predecessor; but in 1872 the colonial assembly passed an act vesting in Dr. Colenso the property belonging to the see of Natal. In 1871 he published "The new Bible Commentary, by Bishops and other Clergy of the Anglican Church, critically examined." In 1872 appeared an abridgment of his work on the Pentateuch, and in 1873 "Lectures on the Pentateuch and the Moabite Stone," with appendices.

COLEOPTERA. See BEETLE.

COLERAINE, a maritime town and parliamentary borough of Ireland, county of Londonderry, situated on both sides of the river Bann, 4 m. from the sea, and 47 m. N. W. of Belfast, on the railway from Belfast to Portrush; pop. in 1871, 6,236. It is distinguished for the manufacture of a fine quality of linen called coleraines. It is fast improving in spinning and weaving factories, and also in pork-curing establishments. There is regular connection by steamer with Toome, and arrangements were completed at the beginning of 1873 to increase the depth of water in the river Bann, so as to enable larger vessels to discharge their cargoes on the quay of Coleraine. It is connected by a handsome bridge over the Bann with the village of Killowen or Waterside.

COLERIDGE, Hartley, the eldest son of Samuel Taylor Coleridge, born at Clevedon, near Bristol, Sept. 19, 1796, died at Rydal Water, Jan. 6, 1849. His birth was commemorated by his father in two sonnets, and his early peculiarities were described and his wayward career almost prophesied in an exquisite poem addressed to him when six years old by Wordsworth. He was reared in the lake district in the north of England, and after a visit to London in 1807 he and his brother Derwent became day scholars of a clergyman at Ambleside. Yet the best part of his education was by intercourse with the friends of his father; and he speaks of himself as having been formed by the living voice of Coleridge, Southey, Wordsworth, Lloyd, Wilson, and De Quincey. In his school days he showed both imaginative and conversational powers by weaving long and wild stories, the recital of which would occupy him and his listeners night after night for months. In 1815, having become a student at Merton college, Oxford, his accomplishments and brilliant conversation gained him numerous invitations to social gatherings, and he acquired habits of wine-drinking over which he afterward had little control. He passed a highly honorable examination for his degree in 1818, and obtained a fellowship at Oriel college; but before the close of his probationary year his intemperance caused the forfeiture of this position. The punishment fell heavily upon his sensitive temperament, and in his despondency and morbid consciousness of shame he resisted less and less the weakness which had caused the overthrow of his fortunes. He left Oxford and resided for two years in London, contributing his first sonnets to the "London Magazine." A scheme to receive pupils at Ambleside failed, and proved that he was unfit for any future exertion of the kind; yet he remained till his death in the lake district, excepting a short residence at Leeds, beloved by all his neighbors and watched over by the family in whose house he lived. His father expressed in his will great solicitude to secure to him the tranquillity necessary to the exercise of his literary talents, and by a bequest provided him with "the continued means of a home." Wordsworth was his near neighbor, and was most attentive to the child-like man whose life he had traced from the cradle. Hartley was a diligent reader, a deep thinker, and an easy writer. His verse and his prose are alike exquisite. His sonnets are among the finest in the English language, and his volume of biography, the "Lives of Northern Worthies," is written in a pleasant, vivacious style, with a vein of fine philosophy. During his latter years he wrote a "Life of Massinger," and many short poems. His grave is in the Grasmere churchyard, by the side of that of Wordsworth.

COLERIDGE, Henry Nelson, an English lawyer and author, nephew of Samuel Taylor Coleridge, born about 1800, died Jan. 26, 1843. He was first a scholar at Eton, and became in due course a scholar and subsequently a fellow of King's college, Cambridge, where he received the degree of A. B. in 1823. While in college he won several prizes for Greek and Latin

odes, was recognized as a man of superior talent and scholarship, and was associated with Praed, Macaulay, Moultrie, and others of his university, in writing for "Knight's Quarterly Magazine." His papers, which were under the signature of "Joseph Haller," treated chiefly questions of English history, and were distinguished for their soundness of opinion and breadth of view. On account of ill health in 1825 he accompanied his uncle, the bishop of Barbadoes, on a voyage to that island, and on his return published a lively and very successful narrative of his experiences, under the title of "Six Months in the West Indies." He was called to the bar in 1826, and attained a good practice in the court of chancery, but devoted his leisure to an assiduous study of literature, and to the society and conversation of his uncle, S. T. Coleridge, whose daughter he married. In 1830 he published an "Introduction to the Study of the Greek Classic Poets." A more important task devolved upon him as literary executor of his uncle, and under his care the volumes of the "Table Talk," "Literary Remains," and "Confessions of an Inquiring Spirit" were given to the public. He endured a painful illness during the latter years of his life, and was often prostrated for months, but suffered with a cheerful mind.

COLERIDGE, Sir **John Duke,** an English lawyer, son of Sir John Taylor Coleridge, born in 1821. He studied at Eton and at Balliol college, Oxford, and became fellow of Exeter college. He was called to the bar in 1847, was recorder of Portsmouth from 1855 to 1865, and was made queen's counsel in 1861. In 1865 he was returned to parliament for Exeter, in 1868 was made solicitor general, and in 1871 attorney general. In 1873 he became chief justice of the court of common pleas.

COLERIDGE, Sir **John Taylor,** an English judge, nephew of Samuel Taylor Coleridge, born at Tiverton in 1790, died Feb. 11, 1876. He received his education at Corpus Christi college, Oxford, where he distinguished himself by brilliant scholarship, and in 1819 was called to the bar. For many years he went the western circuit, and in 1835 he was appointed a justice of the king's bench. For 23 years he occupied this post, retiring in June, 1858, when he was appointed a privy councillor. On the occasion of his retirement from the bench, in the presence of a full court, the attorney general addressed him in behalf of his associates at the bar in an impressive speech, to which Justice Coleridge feelingly replied. His remarks are memorable as containing advice to the younger members of the profession directly in conflict with the dogma of Lord Brougham, that the lawyer should know nobody but his client and no interests but his client's interests. He became editor of the "Quarterly Review" upon the retirement of Gifford in 1824; but resigned in 1825, on account of his professional engagements, and was succeeded by Lockhart. He published an annotated edition of Blackstone's "Commentaries" (4 vols., 1825), and a "Memoir of the Rev. John Keble" (1869).

COLERIDGE, Samuel Taylor, an English poet and philosopher, born at Ottery St. Mary, Devonshire, Oct. 21, 1772, died at Highgate, London, July 25, 1834. He was the youngest child of a learned and singularly amiable clergyman, and became an orphan at the age of nine years. By the kindness of a friend he was presented to Christ's hospital, in London, where he received the principal part of his education, and began a lifelong intimacy with Charles Lamb, who was one of his schoolfellows. His juvenile character prefigured his future career. He was a playless day-dreamer, solitary and uninterested in the ordinary amusements of childhood; yet he made great advances in classical knowledge, and was early distinguished by rare powers of discourse. Charles Lamb speaks of him as "the inspired charity boy, to whom the casual passer through the cloisters listened entranced with admiration, as he unfolded in deep and sweet intonations the mysteries of Iamblichus or Plotinus, or recited the Greek of Homer or Pindar." Before his 15th year he had read through a London circulating library, catalogues, folios, and all, and had bewildered himself in metaphysical studies and in meditating on the problems of theology. So great was his pleasure in abstract speculations that he describes himself as having lost all interest in particular facts, in history or romance, and even poetry seemed insipid to him. Without ambition or worldly wisdom, he at one time proposed apprenticing himself to a shoemaker whose shop was near the school. In his 17th year the sonnets of William Lisle Bowles were presented to him, and such was his admiration of them that he used frequently to transcribe them for presents to the friends for whom he had most regard. These simple poems recalled his idealizing mind to a juster estimate and love of realities, and having in 1791 become deputy Grecian, or head scholar, at Christ's hospital, he obtained a presentation thence to Jesus college, Cambridge. He remained in the university but two years, during which he paid no attention to mathematics, but gained the prize for a Greek ode. At the outbreak of the French revolution he became obnoxious to his superiors from his acceptance of the revolutionary principles. With an enthusiastic and hopeful view of human nature, and an impetuous zeal in the cause of freedom, he hailed the early events of that epoch of continental history as the promise of a new era. His feelings at this period form the theme of one of his odes, entitled "France," and pronounced by Shelley the finest ode of modern times. Suddenly leaving Cambridge in the midst of his university career, he wandered about for a day or two in London, gave his last penny to a beggar, and enlisted in a regiment of cavalry under the assumed name of Comberback. The poet, however, made but an awkward dragoon, and wrote letters for his comrades while they attended to his horse and

accoutrements. After four months' service, a Latin sentence which he had inscribed on the stable wall under his saddle revealed his scholarship, and the captain of his troop, having succeeded in learning his real history, restored him to his friends. He now became associated at Bristol with two other poetical enthusiasts, Southey, a student from Oxford, and Lovell, a young Quaker. Southey, like Coleridge, was an ardent republican and Unitarian, and for his faith had just forfeited the honors of Oxford. These three conceived a splendid scheme of emigration. They determined to found amid the wilds of the Susquehanna a commonwealth which was to be free from the evils and turmoils which then agitated the world, in which a community of goods was to be enjoyed, and from which selfishness was to be proscribed. But this scheme of pantisocracy, as it was termed, failed from want of money and from other practical difficulties; and the three pantisocratists, having married in 1795 three sisters, the Misses Fricker of Bristol, began to turn their attention to the reformation of England. Coleridge had already collected a small volume of his juvenile poems, for which he had received 30 guineas from a benevolent and appreciative publisher, Mr. Joseph Cottle; and he now entered upon an undertaking from which he expected great results, namely, the establishment of a periodical in prose and verse to be entitled "The Watchman," and to advocate liberal opinions. He himself canvassed the northern manufacturing towns for subscribers, preaching wherever he stayed on Sunday in Unitarian chapels, and returned with a subscription list full of promise. Yet the periodical, owing partly to a want of punctuality in its issue, partly to its learned philosophical contents, and partly to the fact that its opinions were not those which its supporters had expected, was dropped at the 10th number with a loss. In 1796 Coleridge took a cottage at Nether Stowey, in Somersetshire, where his means were increased by receiving into his family a Cambridge friend and poet, Charles Lloyd, the son of a wealthy banker, who, merely from love and admiration, had proposed living with him. He published in 1796, in connection with Charles Lamb, a small volume of poems, the greater number of his own contributions to which had been written at earlier periods; and to a second edition in the next year verses were added by Lloyd. Wordsworth having moved to Allfoxden, about two miles from Stowey, the kindred feelings of the two poets united them in the closest friendship. They rambled together over the Somerset hills, discussing the principles of poetry and planning their famous lyrical ballads. It was in this happiest period of Coleridge's life that he wrote his most beautiful poetry, the first part of "Christabel," the "Ancient Mariner," and the "Ode to the Departing Year;" and a mutual resolution of the poets to write a play produced his tragedy of "Remorse." He received in 1798 an invitation to become a Unitarian minister in Shrewsbury, and preached his probation sermon there, the great impression produced by which has been recorded by Hazlitt, who was one of his audience; but he did not preach again. The munificence of Josiah Wedgwood enabled him to visit Germany, and immediately after the publication of the "Lyrical Ballads" he and Wordsworth set out upon the journey together. He attended the lectures of Blumenbach and Eichhorn at Göttingen, formed an acquaintance with Tieck, and obtained a familiarity with German literature and philosophy. At no other period of his life did he work so industriously as during his residence in Germany; and on his return in 1800 he brought back, in addition to his mental acquisitions, a large collection of materials for a life of Lessing. He passed six months in London engaged in translating Schiller's "Wallenstein," and in writing for the "Morning Post;" after which he joined Southey, who had settled at Keswick, amid the lakes and mountains of the north of England, in the neighborhood of Wordsworth, who resided at Grasmere. His opinions had now changed; the republican had become a royalist, and the Unitarian a devoted champion of the established church. In 1804 he went to Malta, hoping to improve his health, and acted as secretary to Sir Alexander Ball, the governor. He returned in 1806 by the way of Sicily and Italy, his health not improved; nor was improvement to be expected, since he went to Malta an opium eater, and returned with the habit growing upon him. His nominal residence from this time till 1810 was at Keswick, but his absences were frequent, and his returns, according to Southey, more incalculable than those of a comet. He was often with Wordsworth at Grasmere, was occasionally in London lecturing, and during the year 1809 was engaged in writing "The Friend," his second periodical, which extended to 27 numbers. In 1810 he left the lakes for London, and resided for a time with Mr. Basil Montagu. He then made his home for three or four years with Mr. Morgan at Hammersmith, and in 1816 placed himself under the care of Mr. Gillman, a surgeon at Highgate, in the hope that he might be broken of his fatal propensity to opium. In Mr. Gillman he found the kindest of friends, and lived in his house during the last 18 years of his life. It was here that he published the wild and wondrous tale of "Christabel," which had been written long before his second tragedy, entitled "Zapoyla," and several prose works, the principal of which were his "Statesman's Manual," two "Lay Sermons," "Biographia Literaria," and "Aids to Reflection." Here, too, he was visited by numerous friends and admirers, who came to listen to his marvellous conversation. The published volumes of his "Table Talk" can give but a faint idea of those extraordinary monologues which attracted many thoughtful

young men to the feet of the sage of Highgate. With an infirm will, he could not overcome the irksomeness of writing out his dreamy idealities and preternatural subtleties of thought; but the gentle excitement of a social circle loosed his powers, and he uttered his lightest fancies and most comprehensive speculations without impediment. His discourse can be judged now only by the effect which it is recorded to have produced upon the listeners, and in his happiest moods it must have been magnificent and most impressive.—The poems of Coleridge exhibit his manifold powers. They comprise tragedy, songs of love, strains of patriotism, and wild, shadowy tales of superstition; they are marked sometimes by a mysterious and wondrous imaginative witchery, sometimes by philosophical thought and retrospection; and their style is according to the subject, either most melodious and flowing, or severe and stately. Several of them are fragmentary, but have no other imperfection, all that there is of them being faultless. The "Rime of the Ancient Mariner," the "Hymn before Sunrise in the Vale of Chamouny," and the unfinished story of "Christabel," are unsurpassed in any language in vivid imagery, solemn intensity of feeling, and skilful modulation of verse. No other poems could so justly be termed purely, absolutely imaginative. The musical versification of "Christabel" delighted Byron and Scott, and was imitated by them both; it was the acknowledged model of the metre of the "Lay of the Last Minstrel." His translation of Schiller's "Wallenstein" is equally remarkable. His tragedy of "Remorse" was brought out with great success at Drury Lane in 1813, but exhibits scenery and sentiment rather than character, and has not since been revived. The prose writings of Coleridge embrace theology, metaphysical and political philosophy, and literary criticism. His philosophical, more than his poetical works, are marked by a splendid incompleteness, and much as they have served to stimulate and direct the minds of others, they do not contain a fully developed system. He was born a Platonist, and he could not rest content, with Locke, to seek all knowledge in phenomena, or with Paley, to seek all good in happiness. His familiarity with the philosophy of Germany, which he first introduced to the notice of British scholars, supplied to him more spiritual theories. Above the understanding which generalizes from the data of perception, and gathers laws from experience, he enthroned the reason which seizes immediately upon universal and necessary truths, and whose intuitions are more certain than sensible phenomena, and more authoritative than the promptings to happiness. It is the clearness and earnestness with which Coleridge has illustrated this truth that has given to his name its philosophical significance, and made him the prompter of many English and American divines and thinkers. He also defended enthusiastically but not clearly the self-determining power of the human will. Coleridge's critical pieces need only completeness to have been alone sufficient to establish his fame. His remarks upon numerous authors and passages scattered upon the margins of books were such as to make his friends always eager to lend him their books for his reading. His review of Mr. Wordsworth's poetry, in the "Biographia Literaria," is one of the most philosophical pieces of criticism in the language; and his lectures upon Shakespeare retain their place notwithstanding the many important works on that author which have more recently been published. The prose style of Coleridge is not always marked by that immaculate taste which distinguishes his poems, but is occasionally disfigured by obscurities and prolixities.—More important than the works which he executed are those which he planned. The life of Lessing, the dream of his German residence, was never really commenced. It was one of his later long-cherished schemes to compose a work of colossal proportions which should embrace the whole range of spiritual philosophy, show Christianity to be the only revelation of permanent and universal validity, unite the insulated fragments of truth, and reduce all knowledge into harmony. He also conceived an epic poem on the destruction of Jerusalem, a subject which would interest all Christendom as the siege of Troy interested Greece. His glowing conceptions and his ambition to achieve some great work, joined to that infirmity of will which made him recoil from effort, he himself has depicted with great pathos in a poem which he addressed to Wordsworth. His life ebbed away in the contemplation of mighty projects, and the legacy which he left to mankind, though a valuable one, was but a fragment from the mine of his genius.—The unpublished writings of Coleridge were carefully edited after his death by his nephew Henry Nelson Coleridge, his daughter Sara, and his son Derwent. All his works have been frequently republished separately. A collected edition, in nine volumes, with an introductory essay upon his philosophical and theological opinions, edited by the Rev. William T. Shedd, appeared in New York in 1853–'4. It also contains James Marsh's admirable preliminary essay to the "Aids to Reflection." The best illustrations of his life are found in the "Personal Recollections" of Joseph Cottle, and in the biographies and letters of his associates, Charles Lamb, Wordsworth, and Southey. The "Fragmentary Remains of Sir Humphry Davy," edited by his brother John Davy (London, 1858), contains letters by Coleridge.

COLERIDGE, Sara, the only daughter of Samuel Taylor Coleridge, born at Keswick, Dec. 22, 1802, died May 3, 1852. She is described as the inheritor of her father's genius, and her life until her marriage was passed at Keswick in diligent study, in mountain rambles with Wordsworth, and in lending literary assistance

to Southey. At the age of 19 she made an admirable English translation of Dobrizhoffer's "Account of the Abipones, an Equestrian People of Paraguay" (3 vols., 1822). In 1829 she married her cousin Henry Nelson Coleridge, and devoting herself to domestic duties, her next publication was entitled "Pretty Lessons for Little Children," which was primarily designed for her own children, but speedily passed through several editions. On the death of her father her husband was appointed his literary executor, and she assisted in editing his works; and after the death of her husband she took upon herself the whole of the important duty. She edited alone the "Aids to Reflection," "Notes on Shakespeare and the Dramatists," and "Essays on his own Times;" and the elaborate discourses on weighty matters which she affixed to these works manifest both her erudition and her critical and logical ability. The beautiful romance of "Phantasmion" (1837) reveals also her imaginative faculty, and, though not in verse, is poetry from beginning to end. Yet in the annotations upon the writings of her father will be found the best evidence of her rare gifts and acquirements, and the chief foundation of her literary reputation. A memoir of her life, with selections from her letters, by her daughter, was published in 1873.

COLES, a S. E. county of Illinois, intersected by Embarras river; area, 550 sq. m.; pop. in 1870, 25,235. The surface is diversified by forests and prairies; the soil is fertile. The Indianapolis and St. Louis railroad and the Chicago division of the Illinois Central pass through it. The chief productions in 1870 were 157,136 bushels of wheat, 2,133,111 of Indian corn, 315,954 of oats, 161,925 of potatoes, 22,371 tons of hay, 260,409 lbs. of butter, 59,017 of wool, and 50,102 gallons of sorghum molasses. There were 9,397 horses, 5,448 milch cows, 11,364 other cattle, 20,546 sheep, and 33,619 swine; 8 flour mills, 10 saw mills, 1 brewery, 2 manufactories of boots and shoes, 1 of agricultural implements, 1 of bricks, 17 of carriages and wagons, 3 of furniture, 1 of iron castings, 4 of marble and stone work, 7 of saddlery and harness, 5 of tin, copper, and sheet-iron ware, 2 of tobacco and snuff, and 2 of woollen goods. Capital, Charleston.

COLES, Cowper Phipps, an English naval officer, born in 1819, died at sea, Sept. 7, 1870. He entered the navy in 1831, and served with distinction on various stations, and particularly in the naval attack upon Sebastopol in October, 1854. He claimed to be the inventor of the system of revolving turrets for the protection of the guns in naval warfare. He says that the idea was suggested to him during the Crimean war, and that in 1855 he sent to the British admiralty drawings for an armored vessel of light draught, "the guns to be protected by a stationary hemispherical tower." No action was taken upon this suggestion. In March, 1859, he sent in other drawings in which this tower, or shield, was placed upon a turn-table, thus rendering it a revolving turret. In 1860 appeared in "Blackwood's Magazine" an article on this subject, with a drawing of such a turret, with the mechanism for turning it by hand. But the invention had been previously set forth by John Ericsson in a memorial to Napoleon III. (1854), and still earlier by Theodore R. Timby, an American inventor, who made a small model of a revolving turret in 1838, filed a caveat in the patent office in 1841, and publicly exhibited a large model in 1843. (See IRON-CLAD SHIPS.) After the success of the experiment of the Monitor in 1862, however, Coles put forth a statement in which he says: "My plans were so exactly similar to that of the Monitor, that I think it will be apparent that this invention is of English origin, and I claim it." In 1864 the British government had a man-of-war, the Royal Sovereign, altered into a "shield" ship under the direction of Capt. Coles, and subsequently constructed several other turreted vessels. One of these was the Captain, an iron vessel, which foundered off Cape Finisterre, and of 540 persons on board only 17 were saved. Among those lost was Capt. Coles, who was a passenger.

COLET, John, an English clergyman, born in London in 1466, died there, Sept. 16, 1519. He completed his education at Oxford, and afterward visited France and Italy. On returning to England he was ordained, delivered at Oxford free lectures on the epistles of St. Paul, and was successively appointed rector of Dennington in Suffolk, prebendary of York, canon of St. Martin's-le-Grand, London, and dean of St. Paul's. He was one of the first of the Anglican clergy who introduced the custom of expounding the Scriptures on Sundays. This innovation caused Dr. Fitzjames to denounce him as a heretic, but the archbishop dismissed the complaint. In 1508 the dean conceived the idea of founding and endowing a school in which the children of the poor should receive a free education. This institution was completed in 1512, and, from its connection with the cathedral, was denominated the St. Paul's school. He wrote various philological and devotional works, the most important of which are his "Accidence," "Syntax," "Daily Devotions," and "Monitions to a Godly Life."

COLET, Louise, a French poetess, born at Aix, Sept, 15, 1810, died in Nice in 1876. Her maiden name was Révoil, and she married in 1835 Hippolyte Colet of Nîmes, a musical composer. Soon after her marriage she accompanied her husband to Paris, where he became professor in the conservatory. In 1837 she published a volume of poems, *Fleurs du midi*, which was criticised by Alphonse Karr with so much severity in *Les Guêpes* that the author attempted to stab him with a knife, and was subjected to some ridicule in consequence. She did not, however, abandon literature, but published various novels in the

Revue de Paris, one of which, *Silvio Pellico*, attracted much attention. She obtained the prize for poetry from the French institute in 1839 (also in 1843, 1852, and 1854), and was granted a pension by the government. In 1842 she became one of the circle frequenting the salon of Mme. Récamier, upon whose death her own salon became a resort of the literati of Paris. Her husband died in 1851, and she went to England, whence she returned in the following year. In 1859 she went to Italy, where she wrote *Madeleine*. George Sand having published a representation of her relations with Alfred de Musset in a book entitled *Elle et lui*, Paul de Musset, his brother, answered it with *Lui et elle*. To this Mme. Colet while in Italy wrote a reply in a romance entitled *Lui*, of which several editions were published. In 1864 she went again to Italy, where a strong prejudice was excited against her on account of the supposed irreligious tendencies of her writings, and her house at Ischia was surrounded by a mob who threatened her life. Among her volumes of poetry are *Le marabout de Sidi Brahim*, *Réveil de la Pologne*, and *Le poëme de la femme;* and among her romances and prose works are *La jeunesse de Mirabeau*, *Histoire d'un soldat*, *Folles et saintes*, *Deux femmes célèbres* (1846, republished in 1854 under the title of *Mme. Duchâtelet*), *Deux mois dans les Pyrénées*, and *L'Italie des Italiens* (4 vols., 1862–'4). She also published dramas entitled *La jeunesse de Gœthe*, *Charlotte Corday*, and *Madame Roland*, and various translations. Among her latest works are *Les derniers marquis*, *Courtisanes de Capri*, *Journée d'une femme du monde*, *Satires du siècle*, and *Les derniers abbés* (1869).

COLFAX. **I.** A N. E. county of Mississippi, formed since the census of 1870, bounded E. by the Tombigbee river, and S. partly by the Oktibbeha, which with its branches intersects the W. portion; area, about 400 sq. m. The surface is level; the soil fertile and well adapted to cotton. The Mobile and Ohio railroad passes through the county seat. Capital, West Point. **II.** An E. county of Nebraska, bounded S. by the Platte river, and watered by Shell and Maple creeks; area, about 500 sq. m.; pop. in 1870, 1,424. The Union Pacific railroad passes through it, and the Elkhorn Valley road will cross the N. E. corner. The chief productions in 1870 were 13,529 bushels of wheat, 27,164 of Indian corn, 15,017 of oats, 8,354 of potatoes, and 2,203 tons of hay. There were 231 horses, 351 milch cows, 423 other cattle, and 295 swine. Capital, Schuyler. **III.** A N. E. county of New Mexico, formed in 1869 from Mora co., bounded N. by Colorado and W. by the Rio Grande; pop. in 1870, 1,992. In the western portion gold has been found, and in 1871 there were two quartz mills. The chief productions in 1870 were 5,491 bushels of wheat, 11,000 of Indian corn, 14,398 of oats, 836 tons of hay, and 13,500 lbs. of wool. There were 56 horses, 355 milch cows, 1,726 other cattle, 9,300 sheep, and 427 swine. Capital, Elizabethtown.

COLFAX, Schuyler, 17th vice president of the United States, born in New York city, March 23, 1823. His grandfather, Capt. Colfax, was an officer of the revolutionary army and the commandant of Washington's body guard. His father died before Schuyler was born, and when he was ten years old his mother married again, and for the next three years he was employed in his stepfather's store. In 1836 the family emigrated to Indiana, and settled in New Carlisle, St. Joseph co. During the five following years Schuyler was a clerk in a country store. In 1841 his stepfather, Mr. Matthews, was elected county auditor and removed to South Bend. Schuyler was appointed his deputy and began to study law; but after serving for two years as senate reporter for the Indianapolis "State Journal," he established in 1845 a weekly paper at South Bend called the "St. Joseph Valley Register," of which he was both proprietor and editor. In politics it supported the whig party, and in 1848 Mr. Colfax was sent as a delegate to the whig national convention at Philadelphia, of which body he was elected secretary. In 1850 he was a member of the Indiana state constitutional convention, in which he spoke and voted against the clause prohibiting free colored persons from entering the state. In 1851 he was a candidate for congress, and was defeated by a majority of only 216, though his district was strongly democratic. In 1852 he was a delegate to the whig national convention at Baltimore, which appointed him its secretary. Two years later he was elected a representative in congress by the newly formed republican party, and was reëlected for the six following terms. In 1856 he supported Mr. Fremont for president, and during the canvass a speech made by him in congress, on the extension of slavery and the aggressions of the slave power, was circulated to the extent of more than half a million copies. In the 35th congress Mr. Colfax was made chairman of the committee on post offices and post roads, which place he continued to occupy until his election, Dec. 7, 1863, as speaker of the 38th congress. He was reëlected speaker in 1865, and again in 1867. In 1865 he made a journey across the continent to the Pacific coast; and in May, 1868, the republican national convention at Chicago nominated him for vice president of the United States, with Gen. Grant as candidate for president. He received 522 votes of the 650 that were polled by the convention, and was elected in November; and on March 4, 1869, he was inaugurated vice president, and took his seat as president of the senate. In 1870 he wrote a letter, which was published, declaring his purpose to withdraw from public life at the close of his term as vice president. He was subsequently led to change this determination, and in the republican na-

tional convention at Philadelphia in 1872 he was a candidate for the nomination as vice president, and received 314½ votes, 384½ being given to Henry Wilson of Massachusetts, who was accordingly nominated on the first ballot and chosen in the subsequent presidential election. In 1873 Mr. Colfax was implicated in the charges of corruption brought against members of congress who had received shares of the crédit mobilier of America, and was repeatedly examined before the congressional committee appointed to investigate the matter. A resolution directing the judiciary committee of the house of representatives to inquire if the evidence taken by the committee called for the impeachment of any officer of the government, brought forth a report, on Feb. 24, 1873, declaring that there was no ground for the impeachment of Mr. Colfax, inasmuch as the alleged offence of bribe-taking, if committed at all, had been committed before he became vice president. This report was accepted, and nothing more done with the matter.

COLIC, in its strictest sense, a severe and moving pain in the colon, or large intestine; but pains having their seat in the small intestines, and in any of the abdominal viscera, are now included under this term. Bilious colic is attributed to excessive secretion or acridity of the bile; flatulent colic to the accumulation of intestinal gases; painters' colic to the poisonous and paralyzing influences of lead; hepatic colic to the passage of gall-stones along the biliary ducts. Besides these there are menstrual colic, preceding or accompanying the menstrual discharge; nephritic colic, in inflammation of the kidney, or during the passage of calculi along the ureters; verminous colic, due to the irritation of worms in the intestines; uterine colic, having its seat in the uterus; nervous colic, arising from a spasmodic contraction of any part of the alimentary canal, from the stomach to the colon; so that colic, or shifting abdominal pains, is a symptom of a great variety of diseased conditions, both functional and organic. The disease generally understood by colic has its seat in the small intestines, which seem to be variously rolled and twisted, accompanied by very severe pain and constipation. The treatment is as various as the causes, consisting of opiates to relieve pain, antispasmodics to arrest irregular nervous action, stimulating cathartics and enemata, hot external applications to the abdomen, carminatives to remove flatulence, the inhalation of ether during the passage of biliary and renal calculi, and antiphlogistic and demulcent remedies when accompanied by any inflammatory symptoms. Children are particularly subject to colic, but are easily relieved by familiar domestic remedies. Lead colic will require further mention in its proper place; copper colic resembles it, except that it is generally accompanied by diarrhœa, instead of the obstinate constipation which is so characteristic of the disease produced by lead.

COLIGNI, or **Coligny, Gaspard de,** leader of the French Huguenots, and principal victim of the St. Bartholomew massacre, born at Châtillon-sur-Loing, Feb. 16, 1517, murdered in Paris, Aug. 24, 1572. He was introduced in 1539 to Francis I. by his uncle, the great constable Anne de Montmorency, and was knighted for his services in the battle of Ceresole, and appointed to the command of an infantry regiment. He soon acquired the reputation of being one of the best officers in the army. His stern sense of duty and indomitable bravery contrasted in a striking manner with the gay and frivolous disposition of the young nobles of his time. On the accession of Henry II. he was promoted to the rank of colonel general of the French infantry. Owing to his skilful efforts the strictest discipline soon prevailed among soldiers who had heretofore been notorious for insubordination. The rules he established became the basis of the French military code, and he may be regarded as one of the founders of the French system of infantry. Soon afterward he received the commission of admiral, which office, being more of a military than naval character, placed him in power next to the constable. His colonel-generalcy he resigned to his brother Dandelot. He accompanied Henry II. in his conquest of the "three bishoprics," Metz, Toul, and Verdun, and subsequently contributed to the victory won at Renty by the French over the army of Charles V. Appointed governor of Picardy, he displayed remarkable intrepidity in conducting the defence of St. Quentin against the Spanish troops. Although all hopes of holding the town were gone, Coligni refused to surrender, and was taken prisoner (1557) while fighting desperately at the head of a few soldiers, and sent to the castle of Sluis, where he was confined for several months, but finally recovered his liberty on paying a ransom of 50,000 crowns. With the genius of a warrior he combined the fervor of a religious reformer. He was a devoted Calvinist, having for years meditated upon the opinions promulgated by the great French reformer; and although not yet openly avowing the new creed, he had proved an active supporter of the French Protestants. He now proposed to secure for them a place of refuge, and sent several expeditions to America, one of which, intrusted in 1562 to Jean Ribault of Dieppe, erected Fort Charles on the coast of Carolina, but soon abandoned it and returned to France; another in 1564, placed under the command of Laudonnière, settled near the mouth of St. John's river, Florida, but they were expelled and nearly exterminated by the Spaniards, who claimed the ownership of the country. After the death of Henry II. (1559), Coligni came boldly forward as the leader of the Huguenots, and his attempts to secure religious liberty for his followers having been defeated by the intrigues of the duke of Guise and of Catharine de' Medici, he reluctantly took up arms in 1562.

At the battle of Dreux, fought in that year, the prince of Condé was taken prisoner; and after this prince's death at the battle of Jarnac (1569), Coligni gathered the remains of the Protestant army, and was soon able to confront again the Catholics at Moncontour. In this last encounter he was defeated; but although severely wounded, and unable to ride on horseback, he led the retreat from his litter, preserving such good order and presenting such an unbroken front to the enemy that the Catholics themselves became favorable to a termination of the war, and peace was actually made a few months afterward. It has been very justly said of Coligni that he was never more to be dreaded than after a defeat, and he has been called the "general of retreats." After the treaty of St. Germain in August, 1570, Coligni reappeared at the court, where he submitted to Charles IX. plans for the improvement of his government and the direction of his foreign policy. Charles seemed to receive his advice with great deference, but he was surrounded by courtiers who would not tolerate the influence of a Huguenot, and the great admiral was destined to be the first victim of the massacre of St. Bartholomew. Two days previous to the consummation of this tragedy, Coligni had been shot at from a house belonging to the Guise family by a man named De Maurevel, a creature of the queen. Charles IX. called on the wounded warrior, seemed to sympathize with his misfortune, and swore that the murderer should not escape punishment; but his mother persuaded him that the Huguenots were about to attempt a massacre of the Catholics, and that they must be anticipated. The admiral was abandoned to the same fate which overcame all the other Huguenots. A band of murderers, led by Behme, a German in the service of the duke of Guise, invaded the admiral's house. On entering his room, they were at first subdued by the prestige of his presence; but Behme, soon recovering his presence of mind, stabbed him in the stomach with a boar spear and threw the body into the court, where the duke himself was in waiting. This young prince had always, but unjustly, accused Coligni of having been an accomplice in his father's murder, and could only be satisfied by his death. The head of the unfortunate hero was brought to Catharine, who had it embalmed and sent to Rome. His lacerated remains were dragged through the streets, and at last placed on the gallows at Montfaucon, where it is said Charles IX. went to look at them, accompanied by his courtiers. Some faithful servants of Coligni carried them away during the night, at the peril of their lives, and his cousin Montmorency had them secretly buried in Chantilly. In 1786 Montesquieu transferred them to his estate of Maupertuis, where he dedicated a chapel and a monument in honor of the admiral. After the revolution, the latter was removed to the *musée des monuments français*. Coligni left memoirs of his own time, but they were destroyed. The only work of his which has been preserved is his *Relation du siége de St. Quentin*. An essay entitled *Souvenirs historiques sur l'amiral Coligni, sa famille et sa seigneurie de Châtillon-sur-Loing*, was prepared in 1858 by M. Becquerel, a member of the French academy, and read before that body.

COLIMA. **I.** A state of Mexico, between lat. 18° and 19° 30′ N., and lon. 102° 40′ and 104° 20′ W., bounded N. by Jalisco, E. and S. E. by Michoacan, and S. W. by the Pacific; area,

Colima.

2,393 sq. m.; pop. in 1869, 48,649. It has a coast line of about 100 m. Its surface is generally level, no part of it, excepting a few mountain peaks, rising more than 1,000 ft. above the sea. The climate is very hot, and the soil produces largely. Coffee, tobacco, cotton, cacao, indigo, vanilla, various fruits, and the mulberry grow to perfection. The inhabitants are chiefly Indians.—The volcano of Colima, which is in the state of Jalisco, is 12,000 ft. high, and forms the S.W. extremity of the chain which traverses Mexico from E. to W. For 40 years it had been inactive, and was supposed to be extinct; but on July 12, 1869, it began to smoke, and a few weeks later to pour forth a stream of pumice stone intensely heated, which spread for miles and covered hundreds of acres. It was still in eruption in 1873.

II. The capital and principal city of the state, situated in a fertile plain watered by several rivers, two of which pass the town, in lat. 19° N., lon. 103° 7′ W., 270 m. W. by S. of Mexico; pop. about 20,000. It is a well built city, with regular streets, mostly paved. There are two squares, the principal of which is the Plaza de Armas. It has a government house, a number of churches, a college, and several schools. There is a considerable demand for manufactured goods, cottons, linens, woollens, and hardware. Its port, Manzanilla, 60 m. S. by W. of the city, has fine anchorage and a good commerce with San Francisco. There are no buildings there, it being only a landing place. Colima was founded by Gonzalo de Sandoval in 1522, incorporated under the name of Santiago de los Caballeros by Philip II., and made a city in 1824.

COLLAMER, Jacob, an American senator, born at Troy, N. Y., in 1792, died at Woodstock, Vt., Nov. 9, 1865. He was a son of Samuel Collamer, who was a native of Scituate, Mass., and a soldier of the revolution. In childhood the family removed to Burlington, Vt., and Jacob graduated at the university of Vermont in 1810. He studied law at St. Albans, and was admitted to the bar in 1812, after which he made the frontier campaign as a lieutenant of artillery in the detached militia in the United States service. He accomplished his course of preparatory, collegiate, and professional studies without any other pecuniary means than such as his own industry supplied. Until 1833 he practised law in Washington, Orange, and Windsor counties, commencing at Barre. In 1821, '22, '27, and '28 he represented the town of Royalton in the general assembly. In 1833 he was elected an associate justice of the supreme court of Vermont, and was continued on the bench till 1841, when he declined a reelection. In 1842 he was chosen a member of congress, and was reëlected in 1844 and 1846, but in 1848 declined to be again a candidate. In October, 1848, the whig party of Vermont formally recommended him through a legislative caucus for a cabinet appointment, and on March 7, 1849, he was appointed postmaster general by President Taylor, in which office he continued till July 20, 1850. On Nov. 8, 1850, he was elected judge of the supreme court, and was annually reëlected until Oct. 14, 1854, when he was elected United States senator. He continued in that office until his death, and served as chairman of the committee on post offices and post roads and on that of the library. The degree of LL. D. was conferred upon him by the university of Vermont and by Dartmouth college.

COLLÉ, Charles, a French dramatist and song writer, born in Paris in 1709, died Nov. 3, 1783. He was appointed by the duke of Orleans, the son of the regent, his reader and private secretary, and during 20 years wrote plays for the private theatre of the duke. He also wrote songs, which have more merit than his plays, and were in the same vein with those of his imitators, Desaugiers and Béranger. The plays have been published under the title of *Théâtre de société*, and the songs in two volumes.

COLLE, Raffaellino dal, an Italian painter of the earlier part of the 16th century, studied under Raphael and afterward under Giulio Romano, and was the assistant of both these artists. His manner of painting resembled that of Raphael. He worked for a time under the direction of Vasari. Among his paintings are a picture of the "Resurrection," in the church of St. Rocco at San Sepolcro; an "Assumption," in the church of the Conventuali at Città di Castello; a "Nativity;" and two pictures representing scenes in the life of St. Benedict, painted in fresco, in the chapel of the Olivet monks at Gubbio. Raffaellino is considered one of the best masters of the school of Raphael.

COLLEGE (Lat. *collegium*, an association), in its primary and most general meaning, the union of several persons (*collegæ*, colleagues), with like powers, privileges, and customs, in one office for a common end. Thus, in Roman antiquity, colleges consisted of at least three persons, forming a corporation for religious, political, or industrial purposes. The four principal colleges of priests were the *collegium pontificum*, *C. augurum*, *C. septemvirorum* or *epulonum*, and *C. quindecimvirorum*. These were instituted by the earliest kings, and besides them there were many designed for the service of inferior divinities, or at a later period for the worship of the emperors after their apotheosis. Of the last class the *C. Augustalium* and *C. Flavialium* were examples. Among the Roman political colleges were the *C. Capitolinorum*, which presided over the Capitoline games, the *C. tribunorum plebis*, which protected the plebeians from the abuse of patrician magistrates, and the *C. quæstorum*, which managed the public revenues. There were also from the time of Numa or Servius Tullius colleges of artificers, carpenters, butchers, bakers, locksmiths, potters, and finally of persons engaged in nearly every other branch of industry. Their original design was either to bring the old and new citizens into closer union, or, according to Plutarch, to prevent the danger of any general conspiracy, by organizing separate assemblies, festivals, and finances for different portions of the citizens. During the latter period of the republic these colleges increased in number, and became intriguing and violent parties in the comitia, so that the senate ordered the dissolution of all those newly formed. They were revived during the civil wars, and suppressed by Cæsar and again by Augustus, being regarded as centres of conspiracy. In the Byzantine empire they were encouraged and patronized, in return for which they furnished to the government the products needed for the public services.—Among more recent applications of the term are the *collegium tenuiorum*, a mediæval union of poor men who engaged to procure for each

other proper burial; the sacred college, or college of cardinals, which assembles in conclave and elects the pope; the colleges or courts of admiralty, having maritime jurisdiction at Amsterdam, Rotterdam, Hoorn, and other seaports of Holland; the colleges of the Arminians, or their assemblies held twice each week on Sunday and Friday; the three colleges of electors or their deputies, of princes or their deputies, and of the deputies of imperial cities, which composed the Germanic diet prior to the dissolution of the German empire in 1806; the college of electors of president and vice president in the United States, chosen by the people once in four years for that purpose only; the college of justice, or supreme civil court, of Scotland, embracing the advocates and clerks as well as the lords of council and session; the college of heralds in England, incorporated by charter of Richard III. with various privileges, and subordinate to the earl marshal of England, who held his court of chivalry in its hall assisted by its members; the college of general superintendence in Russia, or that department of government which has direction of all benevolent institutions, schools, and houses for the sick and poor; the London college of civilians, or doctors' commons, founded by Dr. Harvey, the members of which live in a collegiate manner, and in whose common hall the principal spiritual court and the high court of admiralty are held; the London college of physicians, chartered by Henry VIII., and endowed by that monarch and his successors with various privileges, such as the power to inspect the apothecaries' shops and superintend the drugs sold in and about London, and without a license from which no person, though he may have received a medical degree from a university, is permitted to practise medicine within seven miles of that city; the Edinburgh college of physicians, instituted in 1681, to make laws for promoting the art and regulating the practice of physic, having similar powers to those of the corresponding college at London, but obliged to admit the professors of physic in the universities of Scotland as honorary members, and to license all those who have received medical degrees from the universities; and several other European colleges of surgery, medicine, or health, which have both a power of police over matters pertaining to the public health and the privilege of instructing and examining candidates for medical degrees. The oldest of these in Germany was established by Frederick William, elector of Brandenburg, in Berlin, in 1685. This was followed by a similar college of health in each of the Prussian provinces, and in 1725 there were twelve *Provinzial-Collegia medica* under the general supervision of the Berlin *Ober-Collegium medicum*. By the constitution of 1808 the provincial colleges gave way to medical committees, which were organized in 1815 and 1817 as sections of the administrative government. The London college of surgeons, which dates from the reign of Edward IV., is composed of persons empowered to practise the art of surgery in Great Britain, and has 24 councillors and over 500 fellows, with extended rights and privileges. A competent education and at least eight years of surgical practice are requisite before an examination for a fellowship. The Edinburgh college of surgeons has a corporate character as a royal college. It consists of the surgeons of Edinburgh, has the privilege of examining and of licensing or rejecting all practitioners in surgery in the neighboring counties, and its diplomas are recognized by the army and navy medical boards, and by the East India company, as qualifications for their surgeons.—Colleges as departments of a university arose about the beginning of the 13th century. When the repute of the great scholastic teachers had attracted thousands of students to the university towns, collisions became frequent between the citizens and so many for the most part rich and noble youths. In order to secure to the students a more fixed mode of life, so that their manners and morals should be under stricter supervision, hotels or boarding houses were established, in which the scholars lodged together under the direction of a superior. These hotels, which were termed colleges, were gradually endowed by the gifts of charitable persons, till they were able to furnish free lodgings and finally entire support to a certain number of poor scholars. The name college was soon applied to any institution for academic purposes, endowed with revenues, and possessing a private code of laws, whether it were wholly independent or subject to the general government of a university. Collegiate foundations do not appear to have existed in the Saracen schools of Spain, but were first established in Paris, and soon afterward in Oxford and Cambridge, in Bologna and Padua, and in Prague and Vienna. In the 15th century the endowments of popes, kings, dignitaries of the church, and powerful families had made colleges so common in many of the European universities, that every person connected with a university was usually a member of some one of its colleges. Some of them were in the interest of the monastic orders, and their design to train ministers for the church still appears in the prohibition of the fellows of the English colleges from marrying. They were sometimes not only schools for the young, but hospitals for the old. Sion college in London was in the 14th and 15th centuries both a priory and a hospital. It is now a corporation of the clergy of the city of London, and also a hospital for 20 poor men and women. St. Peter's college, Westminster, may also be mentioned, as well as the royal naval college at Portsmouth. Among the oldest French colleges are the Sorbonne, founded about 1250, in which at first 16 students of theology were gratuitously supplied; the collége de Bons Enfants, founded in 1257; d'Harcourt, in 1280; and de Navarre,

in 1304. Though they were charitable institutions, some of them became so renowned for the learning and eloquence of their lecturers that nobles and princes of the blood placed their children in them. In the university of Paris, 15 colleges were founded in the 13th century, and the number has since been increased to about 100, more than half of which are of slight importance. Each college became a distinct faculty, having lectures and disputations only in a single department, and the university was a collection of colleges, each of which gave instruction exclusively in one branch of learning. The colleges in the English universities assumed at first a different character, being not designed to confer instruction, but to administer royal or private munificence in aiding students through the university. The task of instruction was, however, gradually transferred from the university to the colleges, till at present the former retains only such general powers as the conferring of degrees or other honors. Each college, instead of limiting its instructions to one department, assumes the entire task of qualifying its members for degrees. The funds support a certain number of graduates termed fellows, who may retain this position for life, unless they inherit estates of greater income, or marry; and there are scholarships, exhibitions, and other stipends which give entire or partial support to a portion of the undergraduates, all of whom are under the superintendence of tutors. Besides those who receive aid from the foundations, there are other independent students, who are styled, according to their rank and expenditures, noblemen, fellow commoners, or commoners. Oxford has 20 colleges and 5 halls, the latter being merely unendowed boarding places, where each student lives at his own expense. Cambridge has 17 colleges. Gresham college was established in 1575 by Sir Thomas Gresham, founder of the royal exchange. The lectures commenced, after his death, in his own house near Broad street, in June, 1597; and there, too, the founders of the royal society met in 1645. After the destruction of this building in 1768, the lectures were continued in a room over the royal exchange. On Nov. 2, 1843, the present edifice in Basinghall street was opened.—It is only within the last 50 years that collegiate establishments belonging to Roman Catholics and dissenters have enjoyed the privilege of obtaining academic degrees for their pupils, without having to subscribe to the thirty-nine articles. An attempt to remedy this injustice, and to provide a complete university and scientific education for the inhabitants of the metropolis, led to the founding of University college, King's college, and the university of London. The project originated with the poet Campbell and Lord Brougham. The latter in 1825 introduced a bill into parliament for incorporating the university of London, which was lost. The next step was to found and organize the institution at first named London university. The deed of settlement was dated Feb. 11, 1826; the building in Gower street was commenced April 30, 1827, the first stone being laid by the duke of Sussex; and it was opened by an inaugural lecture from Prof. Bell, Oct. 1, 1828. As the course of instruction was free to persons of every creed, and did not embrace positive religious teaching, a warm and persistent opposition was at once set on foot by members of the church of England, supported by Oxford and Cambridge, and even by royalty itself. George IV. gave toward the foundation of a rival establishment the ground on which stood the east wing of Somerset house. The new college, named after him King's college, was incorporated by royal charter Aug. 14, 1829, and opened Oct. 8, 1831. Every effort made to obtain a charter for London university proved ineffectual until Nov. 28, 1836, when two charters were granted by William IV., one to London university, the name of which was now changed to University college, and the other establishing the university of London. This latter obtained a new charter in 1837, empowering it to confer degrees on the pupils of King's college, as well as those of University college and all other like proprietary collegiate institutions in England. These powers have again and again been enlarged, and the university of London is now (1873) represented in parliament by Robert Lowe, chancellor of the exchequer. Among the many colleges which at the present time are connected with it in the British islands and colonies, the following may be mentioned: Manchester Independent college, founded for educating persons of the Independent persuasion; the Owens college at Manchester, from which theological instruction is excluded; Manchester New college, belonging to the Unitarians; the Catholic colleges of Stoneyhurst, Lancashire (known as a first-rate scientific as well as classical school), and St. Cuthbert's, Ushaw, Durham county, the rival of Stoneyhurst, and in which the historian Lingard counted among his pupils the late Cardinal Wiseman and the late Rev. John Larkin.—Colleges in France are now a grade of public schools, corresponding nearly to the gymnasia of Germany, and educating pupils between about the ages of 10 and 18. They are either state or communal, according as they are sustained by the funds of the state or of particular cities. There are 83 of the former class (termed lyceums since 1850), including 5 in Paris, under the direction of an inspector appointed by the academy; and 253 of the latter, superintended by the minister of public instruction. The course of study embraces religion, the French, Latin, and Greek languages, one or two foreign modern languages, philosophy, history, geography, mathematics, the natural sciences, and drawing. The college of France, founded by Francis I. in 1530, presents a system of instruction hardly surpassed in vastness by any uni-

versity. Its origin was due to the impulse given to learning in the West by the labors of exiled Greeks from Constantinople, and to the solicitations of Guillaume Budé, a disciple of Johannes Lascaris. Its professors have always borne the name of *lecteurs royaux*. At first having chairs of but three ancient languages, it has now 28 professors and distinct courses, embracing astronomy, mathematics, mathematical physics, experimental physics, medicine, comparative embryology, chemistry, natural history of organic and of inorganic bodies, the law of nature and of nations, comparative legislation, political economy, the ethics of history, archæology, the Hebrew, Chaldaic, Syriac, Arabic, Persian, and Turkish languages, the Chinese, Mantchoo Tartar, Sanskrit, and Greek languages and literatures, Latin poetry and eloquence, Greek and Latin philosophy, the mediæval and the modern French languages and literature, the foreign modern European languages and literatures, and the Slavic languages and literatures. All these courses are gratuitous. Among the distinguished men who have taught in this college are Gassendi, Tournefort, Lalande, Delambre, Cuvier, Ampère, Thénard, Batteux, Rollin, De Guignes, Delille, Andrieux, Sylvestre de Sacy, and Abel Rémusat. This college and the *jardin des plantes* are almost the only establishments of public instruction in France which survived the tumults of the first revolution. Besides the colleges under the direct control of the university, there are in France a large number of proprietary colleges, denominated *colléges libres* according to the law of 1850. The great majority were founded by the clergy; but not a few are under exclusive lay government. Among the latter class are the colléges Ste. Barbe, Stanislas, Rollin, and Juilly; among the former we may mention the collége Ste. Geneviève, belonging to the Jesuits, and the collége de Vaugirard, both of high excellence in scientific and classical education, as well as the collége des Carmes, which under the late Bishop Cruice had the reputation of one of the best scientific schools in Paris.—In Rome many colleges have been founded for the purpose of training able missionaries for the various nations of the globe. The college of the Propaganda was founded in 1627 by Urban VIII., for the education of young men of every color and nationality. The *collegio Romano* was built in 1582 by Gregory XIII., and has ever been exclusively under the management of the Jesuits; besides the splendid library and the Kircherian museum, the Roman observatory is also attached to this college, and under the direction of Fathers de Vico and Secchi has rendered important services to modern science. There are moreover the *collegium Germanicum*, the English, Irish, and Scotch colleges, and two founded by Pius IX., the *collegium Americanum* for natives of the United States, and the *collegium Hispano-Americanum* for natives of Spanish America.—When a separate college contains within itself all the faculties and privileges of a university, it is often designated by the latter name, and therefore the terms college and university are in many cases used indiscriminately. Thus, Trinity college in Dublin is also called a university, and there is no fixed distinction between colleges and universities in the usage of the United States. All American colleges confer degrees in the arts, and the older and more flourishing of them have faculties and give instruction also either in medicine, divinity, or law, or in a few instances in all the professional studies. (Particular accounts of colleges are given under their names in special articles. See also UNIVERSITY.)—The following table, arranged in the alphabetical order of the states, presents a general view of the universities, colleges, and collegiate departments in the United States in 1872, as reported by the United States bureau of education, omitting however many institutions of little importance. The list reported by that department comprises 298 institutions, and the names of 52 others were given from which no information had been received. Many of these institutions, though classified as colleges, are doubtless such only in name, being in fact merely ordinary high schools; but owing to the great difficulties of classification, the results here given possess as high a degree of accuracy as can practically be attained. Many of the colleges in the list have professional schools connected with them which are not included in the results given. Business colleges and institutions for the superior instruction of females, as well as technical and professional schools, are also excluded. For each institution having a preparatory school, the statistics for that department and for the collegiate department proper are presented separately. Of the 298 institutions reported, 217 report collegiate students in attendance. The total number of instructors in all the institutions was 3,040, and of students 45,628, including 19,476 in the preparatory courses, 19,260 in collegiate courses, 6,694 unclassified, and 198 resident or post-graduate students. Among the students were 5,680 females, of whom 4,261 were in the preparatory and 1,419 in the collegiate department. The course of study in 209 of these institutions is reported to be four years, in 9 three years, in 7 two years, and in 25 more than four years, including evidently the preparatory and collegiate courses; while 48 make no report of the number of years in the course. At the last commencement the degree of A. B. was conferred in course upon 1,963 persons, the degree of A. M. in course upon 746, and various honorary degrees were conferred upon 341. There were, however, 124 institutions that made no report of the degrees conferred in course. In Arkansas, Delaware, Florida, Louisiana, Minnesota, Nebraska, Nevada, Oregon, Texas, Colorado, New Mexico, Utah, and Washington territory, no institutions are reported to have conferred the degree of A. B.

COLLEGE HILL, a post village of Hamilton co., Ohio, 6 m. N. of Cincinnati, and the seat of two institutions of learning, viz.: Farmer's college, formerly Carey's academy, founded in 1846, and having in 1870 4 instructors and 45 students; and the Ohio female college, founded in 1848, and having in 1870 13 instructors, 130 students, and a library of 1,000 volumes.

COLLES, Christopher, an American engineer, born in Ireland about 1738, died in New York in 1821. He was educated under the care of Richard Pococke, the oriental traveller, after whose death he emigrated to America, and in 1773 delivered lectures in New York upon inland lock navigation. He was the designer of one of the first steam engines built in the country. In 1774 he submitted proposals for the construction of a reservoir for the supply of the city of New York with water. Afterward he gave instruction to the artillery of the United States upon the use of projectiles, until the arrival of Baron Steuben in 1777, when a change was made in the organization of the department. In November, 1784, he presented a memorial to the New York assembly recommending that Lake Ontario should be connected with the Hudson by means of canals and other improvements. He surveyed the obstructions in the Mohawk river, and the results of the survey were published in 1785. He also published an elaborate pamphlet in regard to inland navigation. The revolution having prevented the construction of the reservoir which he had projected, he offered to undertake the supply of New York from outside of the city by means of pipes, and was probably the first person who drew attention to the subject. He personally explored the roads of the state of New York and published a book describing them. He exhibited much ingenuity in a great variety of employments, but was always poor. At length he was appointed superintendent of the academy of fine arts in New York. He was the friend of Hamilton, Jefferson, and other eminent men, and was honored as the original suggester of the canal system of New York.

COLLETON, a S. county of South Carolina, bordering on the Atlantic, bounded S. W. by the Combahee river; area, 1,672 sq. m.; pop. in 1870, 25,410, of whom 16,492 were colored. The Edisto, Ashepoo, and Salkehatchie are the principal rivers. Much of the land is flat, alluvial, and swampy; the drier parts are fertile. The palmetto and cabbage palm are here indigenous. The South Carolina and the Savannah and Charleston railroads traverse the county. The chief productions in 1870 were 207,927 bushels of Indian corn, 52,825 of sweet potatoes, 2,335 bales of cotton, 8,742,271 lbs. of rice, and 1,040 hhds. of sugar (all that was produced in the state except 15 hhds.). There were 1,679 horses, 4,264 milch cows, 6,237 other cattle, 3,314 sheep, and 17,508 swine. Capital Waterborough.

COLLETON, James, a colonial governor of South Carolina. He was appointed in 1686, during the attempt to carry out Locke's constitution, and in the interest of the lords proprietors, one of whom was his brother. He received with his appointment the dignity of landgrave and 48,000 acres of land. On his arrival he found the colonial parliament unwilling to recognize the constitution, and he at once excluded the refractory members. A new assembly was elected in 1687, in avowed opposition to the governor, and the people resisted his collection of quitrents. The assembly imprisoned his secretary, seized the records, and defied the governor and his patrons. In 1689 Colleton, pretending danger from Spaniards and Indians, called out the militia and declared martial law; but as the militia were the people themselves, this effort was futile. In 1690 William and Mary were proclaimed, and the representatives of South Carolina deposed Colleton and banished him.

COLLETTA, Pietro, a Neapolitan patriot, born in Naples, Jan. 23, 1775, died in Florence, Nov. 11, 1831. He was an officer of artillery and civil engineer, took an active part in politics during the French invasion of Naples, distinguished himself in the army under Joseph Bonaparte, and was made by Murat in 1808 intendant of Calabria, and in 1812 general and director of bridges and public roads. When the Bourbons returned to power, he was for some time imprisoned. On the outbreak of the revolution of 1820 he was sent as viceroy to Sicily, but was soon recalled and appointed minister of war. After the Austrian intervention he was banished to Brünn in Moravia, but afterward he was permitted to reside in Florence. He wrote *Storia del reame di Napoli dal* 1734 *sino al* 1825 (2 vols., Capolago, 1834; 2d ed., 4 vols., 1837; English translation by S. Horner, with a supplementary chapter, 2 vols., Edinburgh, 1858).

COLLIER, Arthur, an English clergyman, born at Langford Steeple, Wiltshire, in 1680, died in 1732. He was rector of Langford, a living which had belonged successively to his great-grandfather, grandfather, and father. In 1713 he published a work entitled *Clavis Universalis*, maintaining the non-existence and the impossibility of the existence of any objects external to the mind. Berkeley had three years before advanced incidentally a similar theory, but the two philosophers appear to have had no knowledge of each other. Collier was inferior to his contemporary rather in the graces of composition than in acuteness or method; and yet, while Berkeley's publication produced a profound impression, the *Clavis Universalis* attracted not the slightest attention in England. In Germany a copious and able abstract of its contents was given in 1717, in a supplemental volume of the *Acta Eruditorum*, and in 1756 a complete translation of it into German was made by Eschenbach. Thus rendered accessible in Germany, Collier has enjoyed among the thinkers of that country high repute for talent and originality. The best view of his

doctrines, as compared with those of Berkeley, is that given by Tennemann. Reid was the first to call attention to the *Clavis Universalis* in England; and in 1837 it was published in London as part of the contents of a volume of metaphysical tracts, which had been prepared for the press by Dr. Parr. In the same year the memoirs of his life and writings, by Robert Benson, appeared in London. The *Clavis* was subsequently reprinted in Edinburgh. Other publications of Collier were the "Specimen of True Philosophy" (1713), the "Logology" (1732), and two controversial sermons. In religion he was an Arian, and also a high churchman on grounds which his associates could not understand.

COLLIER, Jeremy, an English nonjuring clergyman, born at Stow Qui, Cambridgeshire, Sept. 23, 1650, died in London, April 26, 1726. He was educated at Caius college, Cambridge, and became successively chaplain to the countess dowager of Dorset, rector of Ampton in Suffolk, and in 1685 lecturer of Gray's Inn, London. Upon the revolution he engaged in controversy with Bishop Burnet and others, and opposed the new organization of church and state during many years in numerous pamphlets, which were written with great ability. He was imprisoned for a short time in 1688 for a publication in favor of the dethroned monarch. He was again arrested in 1692 on the Kentish coast, on the supposition that he was in communication with the Jacobites across the channel, and refusing to acknowledge the jurisdiction of the court by putting in bail, he was again imprisoned, but was finally released without trial. In 1696, when Friend and Parkyns were condemned for plotting to assassinate King William, Collier attended the prisoners in Newgate, accompanied them to the gallows at Tyburn, and there gave them absolution. The result was that a warrant was issued for his arrest, but he made his escape, and it could not be executed. From his hiding place he published a defence of his conduct, which immediately received many answers, one of which was signed by the two archbishops and all the bishops then in London, 12 in number. He again refused to acknowledge the jurisdiction of the court by putting in bail, and suffered sentence of outlawry, which was not reversed during the remainder of his life. He published in 1697 the first volume of his "Essays upon several Moral Subjects," and in the next year his "Short View of the Immorality and Profaneness of the English Stage." The latter engaged him in a lively controversy with Congreve and Vanbrugh, and the wits of the time. The discussion lasted ten years, and contributed decidedly to the improvement of the English stage. Among his later publications were a translation of Moreri's "Historical Dictionary" (1701–'21), an "Ecclesiastical History of Great Britain" (1708–'14), two additional volumes of "Essays upon Moral Subjects," and a volume of "Practical Discourses" (1725).

COLLIER, John Payne, an English author and commentator on Shakespeare, born in London in 1789. He studied law, and was for several years parliamentary reporter for the "Morning Chronicle" newspaper. He published in journals and reviews criticisms and annotations on the old English poets, in 1820 the "Poetical Decameron," a series of dialogues on the poets chiefly of the reigns of Elizabeth and James I., and in 1825 a poem entitled the "Poet's Pilgrimage." In 1825–'7 he edited a new edition of Dodsley's "Old Plays," adding 11 additional plays to it. In 1831 appeared his "History of English Dramatic Poetry," containing a great variety of information collected from original sources. Many valuable collections, such as the library of the duke of Devonshire and that of Lord Ellesmere, were in consequence of this publication opened to his researches. In Lord Ellesmere's collection of MSS. he found most of the materials for his series of "New Facts" and "Further Particulars" concerning Shakespeare and his works, published between 1835 and 1839. In 1844 he completed the publication of a new life of Shakespeare, and a new edition of his works, for which he had collected materials during 20 years, the text being founded on a new collation of the old editions. In 1852 he published "Notes and Emendations" to the text of Shakespeare, from early manuscript corrections on the margin of a recently discovered copy of the folio of 1632, and the next year a new edition of the plays, with the text regulated by collation of this folio and of other old editions. These publications excited much interest and discussion concerning the date and authority of the manuscript corrections. Mr. Collier has been a zealous member of both the Camden and Shakespeare societies, for which he has edited several interesting works, as the "Memoirs of Edward Alleyn" (1841), the "Diary of Philip Henslowe" (1845), "Memoirs of the principal Actors in Shakespeare's Plays" (1846), and "Extracts from the Registers of the Stationers' Company from 1557 to 1580" (1848–'9). In 1865 he published a "Bibliographical Account of Rare Books" (2 vols.), and in 1866 commenced a series of reprints of the early English poets and pamphleteers. He receives an annual pension from the crown of £100, granted by Sir Robert Peel.

COLLIERY, a term applied to coal-mining establishments, including the mines, buildings, and machinery employed. In their simplest form, as now seen in the Alleghany coal field, where the strata lie nearly horizontal, and generally in the hills or mountains above the level of the streams, or common water level, the collieries employ little or no machinery; but at the deep and extensive mines of the Pennsylvania anthracite fields, and in the older mining districts of Europe, these establishments are of immense proportions, employing hundreds of hands and a vast capital. Primitively, the process of digging coal and other

minerals consisted in simply removing the surface earth, and quarrying the coal on the outcrops of the beds, and this was continued even to a late day. The most notable instance of modern surface coal mining was at the old Summit mines of the Lehigh, where the great

Fig. 1.—The Great Open Quarry of Anthracite, Summit Hill, Mauch Chunk Mountain, Pa.

Mammoth bed was uncovered to the extent of 30 acres, and produced 2,000,000 tons of coal up to 1847, when it was abandoned. The great bed, which was nearly 70 ft. thick at this place, formed an anticlinal with the axis near the surface where the quarry was opened. A tree which had grown over this spot and extended its roots into the coal bed below, having been uprooted by the wind, revealed the coal to a hunter, who reported the discovery, and from this grew the famous Lehigh coal mines. From the quarry method, the next step in advance introduced the art of mining, or under-ground work, and the establishment of collieries. Where the coal beds existed above water level, or near the surface, rude excavations were made into the bed; where they were small, simple galleries were formed in the solid coal from 4 to 12 ft. wide, with arched top and without timber. At the old Butterknowle workings on the southwest outcrops of the Newcastle (English) coal field, these galleries are three yards wide, with square pillars of coal of equal dimensions on each side. These mines are supposed to be 200 years old, and are from 40 to 50 ft. deep. In the Richmond, Va., coal field, galleries of the same character are found, driven at right angles to each other between square pillars, or at random when in faulty ground. These works are also in shallow pits, as all the coal of that field exists below the water level. They are apparently more than 100 years old, and are situated at Springfield on the N. E. edge of the Richmond coal field, where trees over 100 years of age were found during the year 1857 growing on the heaps of waste extracted from them. The most noted of these in the Pennsylvania anthracite fields were on the outcrops of the Mammoth, locally known as the Baltimore bed, near Wilkesbarre, and on the B bed, known as Smith's bed, below Plymouth, in the lower end of the Wyoming valley. These excavations were large, corresponding to the size of these great beds, and wide enough to admit horses and wagons to drive in and turn in the rooms or galleries thus formed.—All or most of the coal of England and Belgium exists below water level, and is mined by pits. Until the application of steam for general purposes in 1800, both coal and water were raised from these mines by horse power or by women; and this was continued even up to 1845, when the employment of women in the mines was prohibited by act of parliament. During 1842, 2,400 girls and women were at work in the mines of Scotland alone, mostly employed in conveying the coal to the surface. In some favored localities near

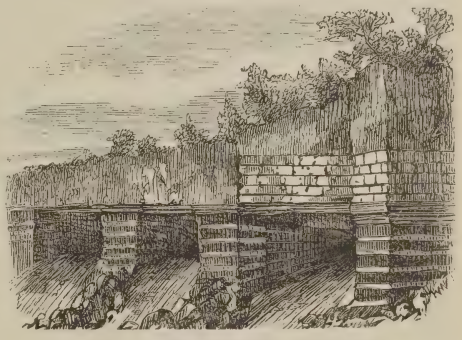

Fig. 3.—The old Baltimore Mines.

the streams, water power was made use of for pumping; in others, horse wains or gins and sometimes hand windlasses were used to raise both coal and water; but more frequently women were employed as beasts of burden, not only to convey the coal along the low entries, in which they could not stand upright, but also up long lengths of ladders from the bottom of small pits to the surface. The work that was performed by women in these old collieries is almost incredible. Robert Bald, in his "General View of the Coal Trade of Scotland" (1808), says: "We have seen a woman take on a load of 170 pounds of coal and travel with this up the dip of the bed, 150 yards, and then ascend a pit by stairs or ladders 117 ft., no less than 24 times during a day of 10 hours." Formerly the colliers of England were practically serfs, and kept in a state of bondage to the proprietors of the collieries where they were born. They were held to be part of the establishment for carrying on the coal mines, and if the mines were leased the colliers were included in the lease. In the

habeas corpus act it was declared "that this present act was in no way to be extended to colliers and salters." But in 1775 an act of parliament declared that colliers and salters were no longer "transferable with the collieries and salt works;" and upon certain conditions they were to be gradually emancipated, while others were prevented from coming into such a state of servitude. Even after the general introduction of the steam engine at the British mines, for raising coal and hoisting or pumping water (though pumps were seldom used until a much later day), women were employed to convey the coal from the mines to the bottom of the pit, a distance of from 100 to 300 yards, with loads of 100 or 150 pounds in bags on their backs, traversing a total distance of nearly 10 miles a day in going and returning. About this time wheelbarrows were also used, and afterward sleds or "cauves," which were pulled by women or boys; and at a still later day "bogies," pushed or pulled by boys, were introduced. These were provided with narrow tram wheels, which ran in grooved rails of wood. Boys of very tender age were employed in the British mines up to a late date to work the "steel mills," which gave light by the production of sparks from a circular wheel armed with steel striking against flints; as "trappers" to open and shut the many doors then used to regulate and guide the air currents; to blow the small fans often used to convey air to points beyond the range of the air currents; and to "put" or push the bogies. But for the last 20 years boys under 12 years of age have been prohibited from working in the British coal mines. In Belgium, however, both women and children are still employed in and about the mines. Wages are so small that it requires the united exertions of fathers, mothers, and children to earn a livelihood.—In England, Belgium, and France, most of the coal lies deep below water level, and can only be reached by expensive pits, which are owned and worked by wealthy proprietors or large companies. In the older mining districts, where the outcrop coal has been long since exhausted, or partially worked by the old methods, in which from half to two thirds of the coal was lost, these pits are constantly growing deeper, and now reach a great depth. W. W. Smith states that a coal pit exists in the province of Hainaut in Belgium, at the colliery des Viviers at Gilly, near Charleroi, which has been sunk 3,411 ft. We do not know that coal has been mined at that

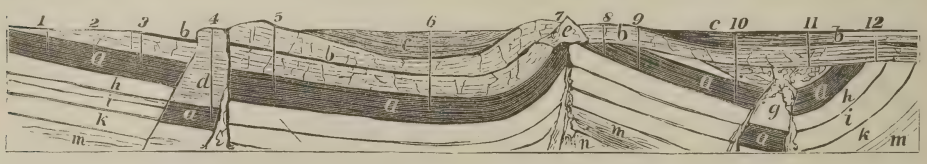

Fig. 4.—English Coal Measures and Unconformable Rock.

depth, however. In many cases these pits penetrate the overlying Permian formation, beneath which most of the carboniferous formations of England and France are concealed, and where the existence of coal was formerly doubted. Indeed, more than two thirds of the English coal measures are supposed to lie beneath the more recent rocks; while over 40,000 sq. m. of France is covered by the Permian, triassic, cretaceous, and tertiary formations, beneath which coal may exist; or, if it does not exist, it is the exception and not the rule. The geological order of the sedimentary rocks requires the existence of the carboniferous below the Permian; and as far as we know, from their outcrop and from the evidence of the deepest pit yet sunk, this succession does in fact prevail, though there may be localities in which the regular order is interrupted. This alone would create doubt, and make the most enterprising cautious. Yet, step by step, the miners of England have approached this doubtful ground, and are now 2,000 ft. beneath the Permian rocks, where no one but William Smith, the father of English geology, ever dreamed of looking for coal in his day. And this advance into unknown ground will doubtless be continued until the deep coal beds, reposing 10,000 to 20,000 ft. beneath the sea, will be won and worked.—In the great American bituminous fields mining operations are much more diversified than in the bituminous fields of Europe. In the Alleghany and central coal fields the carboniferous rocks are the latest and highest geological formations; consequently their wide horizons, covering nearly 100,000 sq. m., may be penetrated at any point without hazard. While the coal of the former is generally found in the hills or mountains, and accessible by drifts or tunnels above the natural drainage, that of the latter is generally below the water level, yet may be entirely developed by pits less than 1,000 ft. in depth. Of the 17,000,000 tons of coal mined from the Alleghany field in 1871, less than 1,000,000 tons were mined below the water level, and the remainder from drift or tunnel collieries, and generally from the former. Drift is a technical term for a tunnel, entry, or gallery driven through the coal horizontally, while the tunnel is a horizontal gallery driven through the rocky strata to reach the coal. The dip or undulations of the strata vary considerably, even in coal fields which have a general dip in

one direction, or that may be nearly horizontal. These elevations and depressions thus formed in the coal beds are locally termed saddles, horsebacks, swells, troubles, &c.;

FIG. 5.—Alleghany Coal Measures.

where they are frequent they interfere seriously with the drainage. In locating collieries these peculiarities of dip are important questions, which may generally be determined by surface indications, when the coal beds and accompanying strata are above the water level. Yet hundreds of thousands of dollars are frequently expended in building railroads, houses, and other colliery appurtenances, before these preliminary investigations are made, and when it is too late to remedy the great inconveniences entailed. Many instances of this kind might be cited in the Alleghany coal field and elsewhere. One on the Philadelphia and Erie railroad involved $500,000 of useless expenditure. The drift should always be located at the lowest available point of dip (*a*, fig. 5); but if the lowest point to which mining operations should extend cannot be reached by drift, started on the outcrop of the bed and continued horizontally in the same, a tunnel may be made use of commencing in the rocky strata above or below the coal bed, in order to reach the bed horizontally, and secure natural drainage. When this mode is not available, the slope or the shaft method is resorted to. In many parts of the Alleghany coal field and its outlying basins the most productive beds of coal are on or near the tops of mountains, or at a considerable elevation above the valleys. In these situations locomotive railroads are impracticable, and inclined planes are used; they are operated by gravity, the loaded cars in descending drawing up the empty cars. On the Youghiogeny, Pa., and in the Frostburg, Md., mining districts, this form of colliery establishment is in general use; 1,000

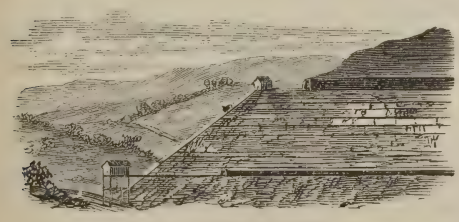

FIG. 6.—Incline and Drifts.

tons of coal per day are sometimes run over a single double-track plane. The most elevated coal of the Alleghany field is about 2,300 ft. above tide, while the lowest is probably 2,000 ft. below the Ohio river, near the mouth of the Great Kanawha, which is considerably deeper than the lowest coals of the central coal field in Indiana, Illinois, or Kentucky, but much less than the deepest coals of the western coal field in Kansas and Colorado, where the lower coal measures are probably 5,000 ft. beneath the tertiary rocks. In the Pennsylvania anthracite fields, however, we find still greater diversity of mining operations as the necessary results of a contorted or highly plicated form of stratification, in which the undulations of dip are most extreme and irregular. In these anthracite coal basins every known plan of drift, tunnel, slope, and shaft is employed. When the coal beds exist in the hills above the water level, drifts and counter-drifts, or upper levels, are used where the outcrop of the bed is exposed in an available locality; otherwise tunnels are made at the lowest practicable point. In these basins the coal beds usually incline at high angles of dip. However high the mountain may be on which they crop out, it is rare that they do not dip below the water level or into the basins at the base of the mountain; and still more seldom are the beds found in horizontal strata, except in the synclinals or at the bottom of the basins, where they often occur in horizontal position before curving to the opposite dip. The great basins of the anthracite fields are generally bordered by parallel mountain ranges, against the sides of which the coal beds crop out. These mountains, particularly in the interior of the fields, are cut through by numerous watercourses, which form gaps or gorges at right angles to the strike of the strata, and in these the outcrops of the coal beds descend to the water level. Thus the broken ends of the strata are exposed, and in these most of the drift collieries of the anthracite basins have been located. But when the outcrops are not thus exposed, and the elevation of the outcrop is sufficiently high above water level, the coal beds are cut by tunnels which penetrate the base of the mountains at right angles to the strike of the strata. When the coal is thus exhausted above the natural drainage, or when the amount of available coal above water level will not justify the expense of a tunnel, the slope method is generally adopted, particularly where the angle of dip is great. The slope is always formed in the coal, except when the undulations of dip require it to pass a short distance in the overlying or underlying strata. In this respect, technically speaking, the slope differs from the oblique or underlying shaft, which penetrates the rocky strata to reach the coal; though generally a shaft is perpendicular, however the strata may dip.—In addition to these peculiarities of the Pennsylvania anthracite formations and the consequent form of the mines and methods of development, a singular feature of the colliery establishments is the immense and costly structures known as breakers. These are generally masses of

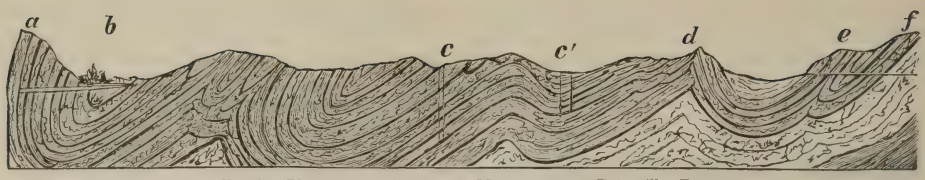

Fig. 7.—Plications of Anthracite Measures near Pottsville, Pa.

heavy framework of great elevation and strength, and are used for the fourfold purpose of breaking, selecting, separating, and storing the prepared coal. The breaker is built near the mouth of the mine, and the coal cars from the drift, tunnel, slope, or shaft are elevated by machinery to the top of the breaker. Here the coal is dumped into a wide shute provided with bar or flat screens and platforms. The coal is separated by passing over the screens and selected by the workmen on the platforms. The purest and best lump or large coal is thrown into a bin provided for the purpose, while the second size, or steamboat coal, passes into a second bin; and the remainder, excepting the dirt and slate or impurities, is put through the breaking rolls, which consist of from two to four heavy iron rollers provided with steel or chilled cast-iron teeth. In passing through these, the coal is broken into small pieces, and descends into a system of large circular screens which are constantly revolving, and which separate the coal into sizes known as pea, chestnut, stove, egg, and broken coal; and sometimes a larger size used for large ranges or heaters in hotels, puddling furnaces, &c. The sizes above this are steamboat and lump, which last is the largest, and generally used for blast furnaces, though the steamboat size is often mixed with the lump for this purpose. Formerly this preparation of anthracite was exceedingly wasteful, owing to imperfect breaking machinery, and a careless habit of crowding the whole mass, both large and small coal, through the breaking rolls without regularity or order. It is estimated that 20 to 25 per cent. of the coal was thus lost. To these defects must also be added that both pea coal and chestnut were wasted in "dirt banks" during the early days of the anthracite trade. Those old banks now yield a large amount of small or screened coal, the remainder being convertible into pressed blocks of patent fuel, or carbonic oxide gas as a fuel. The waste is now considerably less, as the chestnut, pea, and sometimes lime burners' coal is screened, and only the dust and impurities are rejected, which in well

Fig. 8.—Drift with dip and strike of inclining coal beds.

Fig. 9.—Slope, underground tunnel, and coal breaker.

arranged colliery establishments do not much exceed 10 per cent. of the whole. Yet this does not include a much greater waste in the inside of the mines, where a large percentage of small coal is often left in the "goaf," and not less than one third of the whole bed is abandoned as pillars. At the anthracite collieries, where the imperfect systems of "post and stall" and "pillar and breast" are still in general use, not less than one half the entire contents of the coal beds is wasted or lost; and in some cases the waste is still greater. In comparison with the English bituminous mines, this waste is 25 per cent. greater than that of the longwall and 30 per cent. greater than the bord and pillar systems of mining. The coal breaker was invented by a Mr. Batten, who appears to have conceived the idea from the crushing rollers used in Cornwall, England, for the purpose of breaking copper, tin, and other ores. His patent, however, was seriously defective, in not specifying or claiming the combination of the mechanical devices, instead of the direct application of the toothed rollers to breaking coal, while his patent fees were thought exorbitant by the colliery owners, and were successfully resisted. The invention ruined the inventor, while it has conferred immense benefits upon the anthracite trade. This method was introduced in 1844, before which time the coal was broken to sizes by hand hammers. To break the amount of coal now produced by one of these large collieries would require not fewer than 100 men, and in some cases 200 would be required. There are now more than 400 such coal breakers in use in the anthracite fields. The process is peculiar to the Pennsylvania anthracite mines, where the coal, owing to its great hardness, requires special preparation for economical combustion. It is thought by some that this preparation could be more economically done near the great coal marts, where all the waste, except actual impurities, could be sold, because the coal dust thus wasted is the best portion of the coal.—The Pennsylvania anthracite collieries are not only modified by the peculiar structure of the coal measures, but also by numerous distortions and faults which often seriously interfere with mining operations. The form and character of those faults are as peculiar and varied as the lithological structure. Dislocations of strata and crushed graphitic coal are the predominating forms of fault, but the replacement of the coal by rock and slate or shale is also frequent in the upper and smaller beds; while small local

slips and narrow dikes or walls of rock sometimes occupy cracks in the coal beds, but these do not penetrate above or below the bed. The great dikes and slips found in the English and some of the French coal strata are unknown in American coal fields, which, with the exception of the anthracite fields, are singularly free from faults and dislocations. But the anthracite fields of Virginia and New England are still more seriously injured, and

Fig. 10.—Slip Dike.

even partially destroyed, by faults resulting from excessive heat, violent lateral contraction, and the consequent contortion of the strata and pulverization or partial consumption of the carbon. These irregularities are important considerations in the establishment of collieries, as permanence and success depend greatly on the uniformity of the coal bed and the purity of the coal. These and other considerations have made the anthracite busi-

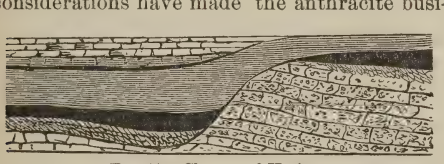

Fig. 11.—Change of Horizon.

ness more precarious and costly than the bituminous, and in all countries where anthracite is mined these peculiarities are observable to a greater or less extent. In addition to the cost of the great coal-preparing establishments, which frequently amounts to $100,000 or $150,000, the expense of sinking the pit or slope and opening the mines is also much greater than in the bituminous regions for corresponding depths. Both the measures

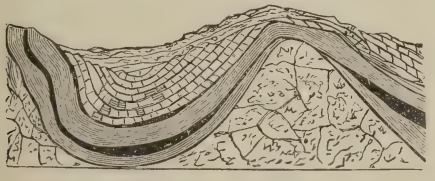

Fig. 12.—"Trouble"—volcanic formations.

and the coal are harder in the former than in the latter; and while the mining is conducted with but little powder in the one, the other requires immense quantities. Anthracite is almost exclusively obtained by blasting. At some of the mines more than 500 kegs of powder are used per month. The value of these collieries ranges from $30,000 to $500,000 each, but the average value cannot be less than $100,000 for the 437 collieries in existence in 1871, at which 52,227 men and boys were employed. The United States census of 1870 makes the value of 1,550 colliery establishments of the country $86,087,251; while the wages paid the 93,805 men and boys employed is given at $43,647,-118. — Hitherto the greatest amount of the Pennsylvania anthracite has been mined from the outcrops of the beds, by drifts, tunnels, and slopes; but as this portion of the beds approaches exhaustion shafts become necessary to penetrate the interior of the basins. The deepest shaft yet sunk in the anthracite fields is the Dundee pit in the Wyoming field, S. W. of Wilkesbarre, which is 700 ft. deep; but it only penetrated the upper beds, when it was

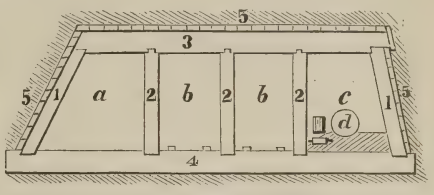

Fig. 13.—Section of Slope.

a, travelling way; *b*, *b*, hoisting ways; *c*, pump way; *d*, pump.—1, 1, legs; 2, centre props; 3, collar; 4, sill; 5, backing or laggins.

abandoned. The next in depth is the great Hickory shaft near St. Clair, in the southern anthracite field, which is 680 ft. deep to the Mammoth bed. Near the latter two large pits are now in progress (1873), which are each expected to penetrate 1,500 ft. to the same bed, and to cut nine or ten workable beds above the Mammoth. The depth of the slopes varies greatly; some of them have penetrated 900 ft. vertically and from 1,200 to 1,500 ft. on the inclination of the bed. The large slopes are often 20 to 24 ft. wide and 7 to 10 ft. high, and provided with two hoisting ways and a double pump way, or a pump and a travelling way. The following table shows the number and condition of the anthracite collieries of Pennsylvania:

DISTRICTS.	No. Collieries.	No. Shafts.	No. Slopes.	No. Drifts and Tunnels.

Total	437	91	293	290

Some of the recent anthracite shafts are of very great size. Several near Wilkesbarre are more than 40 by 20 ft. in dimensions, but this is generally acknowledged to be an unnecessary size in square or oblong shafts, as this form demands timber for support, and the timber must be proportionately large and of great length. This is an element of weakness and danger, and at best only of temporary utility.

The natural decay of wood unfits it for use in pits. But the chief defect is in the form of the pit, and the English mining engineers long since discovered this serious objection to square or oblong pits, and substituted the round pit,

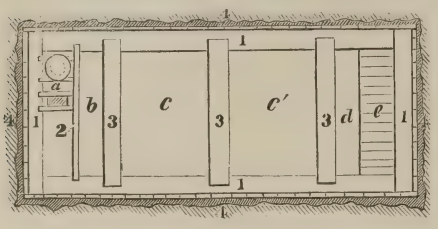

Fig. 14.—Pennsylvania Anthracite Shaft (section).

a, pump and rods; *b*, pump apartment; *c*, *c'*, hoisting apartments; *d*, travelling apartment; *e*, ladders.—1, 1, supporting timbers; 2, pump timbers; 3, 3, 3, dividing timbers; 4, backing plank.

in which brick, stone, or iron can be economically used to secure the sides of the shafts. Besides, this seems to be the only sure method of damming back the water, which in the timbered pits is allowed to enter the shafts and must consequently be pumped out at constant expense. But in circular pits all the water above the coal, and particularly the more abundant surface drainage, which is most seriously felt in the upper 300 to 500 ft., is dammed back with masonry or iron tubing. As the surface drainage always varies considerably in wet and dry weather, a portion of the pit is sometimes wet and sometimes dry, and this alternation, with the incident changes of temperature, induces decay when the pit is timbered, and replacement is dangerous and difficult. The great size of the Pennsylvania anthracite pits is the natural outgrowth of the great size of the coal beds. Nine tenths of the anthracite mines are from beds varying from 10 to 30 ft. in thickness. Mine cars of great size and of unwieldy proportions are used in many of them, with doubtful economy, since the most available systems of mining, known as bord and pillar and longwall, cannot be properly followed in steep-dipping beds with cars of greater capacity than one ton of coal each; yet the cars used in the anthracite mines generally contain from one and a half to three tons of coal, and weigh with their contents as much as five tons. They cannot be taken up the steep pitches by mules or be handled by the men; and this involves a second handling of the coal and some contrivance for getting it from the mines to the cars, which cannot leave the levels or gangways. Shutes are commonly used, but when the dip is too steep to admit the use of mules to draw the cars up to the mines, and too low for the coal to slide down a shute, great trouble and expense are involved. Besides, these systems of breast and pillar or post and stall mining are defective in many other respects. Some of the large anthracite pits are capable of producing 1,000 tons of coal per day; yet this has rarely been accomplished, from the difficulty of handling so many heavy cars at the top and bottom of the pit, or the greater difficulty of getting them to the bottom of the pit through a single level or double gangway, one on each side of the pit, to which the system in use, and the necessity of working the larger beds only, confine most of the anthracite mines. But this production is exceeded by much smaller and deeper English pits, in which cars or bogies holding from 8 cwt. to one ton are used. In some of these deep pits a regular production of 2,000 tons per day is not unusual, though 250 to 500 tons is more common.—The late mining laws both of England and Pennsylvania require two openings for ingress and egress to each mine, so as to secure the safe retreat of the workmen in case of accident, and more perfect ventilation. Some of the most serious and fatal accidents have been occasioned by the absence of a second outlet; one of the most notable was

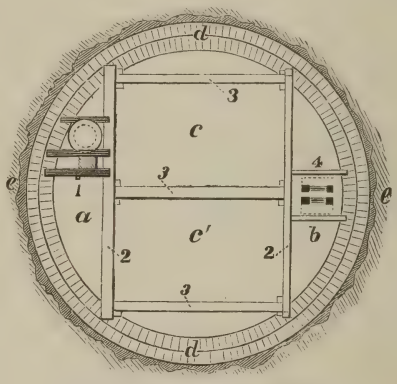

Fig. 15.—English Circular Shaft.

a, pump way; *b*, travelling way; *c*, *c'*, hoisting ways; *d*, brick or stone lining; *e*, rock.

the Avondale disaster, in the Wyoming valley, near Plymouth, Pa., Sept. 6, 1869. This was occasioned in all probability (though the fact was never established) by the exceeding dryness of the timbers in the upcast portion of the pit, which was divided by a partition of wood. One portion of the pit was used for hoisting coal and the admission of air, and the other for the egress of the mine vapors. At the bottom of the latter a furnace was in constant use, the heat from which made the timbers like tinder, and the soot could not fail to accumulate, as in ordinary chimneys. A spark only was necessary to ignite the one or the other. But in other cases, the burning of the structures erected over the pit's mouth, the destruction of a portion of the pit by explosion or caving, flooding of the mine by water, or the derangement of machinery, all point to the necessity of a second outlet from each mine, as a matter of common prudence. The methods of descending and ascending deep pits have been and still are very generally defective and

insecure. In the great mining districts of the world, both in coal and metalliferous mines, the ladder and the hoisting apparatus are the alternatives. To ascend and descend a pit of 1,000 to 1,500 ft. on ladders is nearly a day's work, while descent or ascent on the cages is dangerous. The number of accidents caused by the falling of cages or cars in the anthracite mines during 1871 was 13; and this has always been a fruitful source of mining accidents, partly from the crowding of men anxious to be first at work or first at home, on the cages or into the mining cars. The mining laws of most of the great mining districts prohibit the use of unsafe cages, and the crowding of men on either the car or the cage; but these laws are seldom enforced. The hoisting apparatus, elevators, or lifts used in hotels and manufactories are too slow for mining purposes; and though numerous safety cages have been invented, few if any are perfectly secure. Many "safety-catch" arrangements, however, are in use, which if kept in order would generally prevent serious accidents. The two most practical forms of clutches seem to be the "claw" and the "eccentric." The former are thrust out into the timbers or guides, and the latter hugs the guides on opposite sides when the rope breaks. One defect, however, of all such arrangements, very difficult to overcome, is that they sometimes act during the rapid descent of the cage, which in some cases is equal to the speed of a railroad train, and little short of the motion at the start in falling from a broken rope. Consequently all such devices are defective in pits, and the best cages are unsafe means of conveyance for the workmen. Yet on these, or still more rude and dangerous conveyances, or on ladders, ninety-nine out of every hundred miners depend for descent to and ascent from their work. In a few cases, during late years, "travelling rods" have been used with considerable success, though but rudely contrived and fitted up. They consist of two perpendicular oscillating rods, generally of wood, placed side by side and parallel to each other in the travelling apartment of the pit. Some of these are simply provided with steps, without guards, while in others the rods have platforms securely guarded against danger. In other cases, however, a single rod is used, on which platforms are fixed at intervals, with corresponding stationary platforms in the rock; but the latter plan is much inferior to the former, in which the rods are so balanced that the power required to operate them is but little, while the single rod must be lifted with its weight of men, ascending or descending. In descending the miner steps on one of the moving platforms which comes to the top of the pit, and as this only remains a few seconds, during the slow motion of turning the upper centre of the operating wheel, he must be ready to step on without delay, though a failure to do so would not be dangerous. The motion may be five to ten strokes per minute without difficulty. Immediately on reversing the rod descends 8 to 12 ft., meeting a corresponding platform on the ascending parallel rod; on this the miner steps, and the platform he left ascends, and the one he is on descends. Thus he steps from platform to platform and descends from 100 to 200 ft. per minute. In ascending the same rule is observed, except that the miner steps upon the ascending platform instead of the descending one; but whether ascending or descending, he is alternately now on one, and now on the other; and though 20 or more miners may be going up or going down at once, the balance is always nearly equal. The best mode of constructing these rods is to place them close together, with the platforms on opposite sides; and instead of two, four rods are preferred. In stepping from one platform to the other, the miners pass between the rods. In order to prevent accidents from carelessness or otherwise, the platforms should fit the compartments neatly, so that the men could not even by thoughtlessness endanger life or limb. In the construction of such means of vertical conveyance, in pits of great depth, iron or steel bands, links, or ropes could be judiciously made use of, connected on top by square links over a toothed wheel, making alternate reverse revolutions.—The methods of sinking pits have been considerably improved within a few years, by the use of new mechanical contrivances, or inventions in boring, blasting, and contending with water, quicksands, clays, or hard materials. In blasting, the use of dualline is preferred by miners to other new explosive compounds, on account of its superior safety and effectiveness; while electricity is now generally used by experienced engineers both in sinking and tunnelling. It is not used, nor is it desirable, in ordinary coal or iron mining for the discharge of single blasts; but where the simultaneous discharge of numerous blasts is required, nothing but electricity is available. In the sinking of two deep vertical shafts by the Philadelphia and Reading coal and iron company 1½ m. N. of Pottsville, a novel method was adopted, which promises to produce a revolution in that branch of mine engineering. The mammoth coal bed in that locality lies at a great depth below the surface, estimated to be 1,560 ft., and as the mining law of the state requires at least two openings separated by not less than 150 ft. of solid strata, two shafts were necessary. The plan adopted was

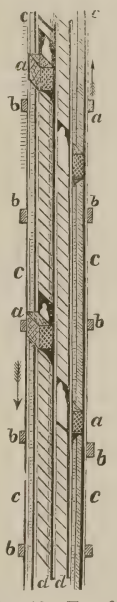

FIG. 16.—Travelling Rods.
a, basket platforms; *b*, *c*, partitions and supports; *d*, rods.

to sink the shafts as usual down to the solid rock, and then by means of a number of diamond drills, each driven by its own machinery, to bore a series of holes about 300 ft. deep. The bit used is concave, with circular grooves and cylindrical holes for the outlet and circulation of water, which is forced down through the centre of the boring rods, made of gas pipe $1\frac{1}{2}$ in. in diameter, and the holes when drilled are $1\frac{3}{4}$ in. The water takes up the fine sand or pulverized rock, carries it away from under the bit, and rises outside of the rods or pipe to the surface. In the W. shaft, which is 25 ft. 8 in. long by 13 ft. 10 in. wide, 35 holes are bored in five rows of seven holes in each, the outside rows being along the sides and in the corners, making the holes 4 ft. 3 in. one way and 3 ft. 6 in. the other from centre to centre. As soon as one of the holes has been bored to the required depth the machine is moved to the next, and the operation is continued until all the holes in the shaft are drilled. Two or three machines can work at the same time on the same bed plate. No cores are removed, all the rock being ground to powder and carried off by the water, and it is therefore not found necessary to take out the rods very often. Steam may be used as the power to drive the boring machines, but in the lower levels compressed air is obviously much better. When all the holes are bored to a depth of 250 or 300 ft. the machines, pumps, &c., are taken to the other shaft to bore the holes there. During the boring in the second shaft the rock is blasted and removed in the first, which requires much more time than the drilling. On the completion of the holes they are filled to the top with sand, and the work of blasting and removing the rock is done by removing the sand by means of a sand pump from all the holes, except those along the sides and in the corners, to a depth of from 3 to 4 ft. Clay is then forced into each hole so as to made a plug 6 in. to a foot long, and on top of this a cartridge of dualline is placed and the holes are then tamped with clay. The cartridges are connected together by wires leading to a galvanic battery, and are all fired at once. The loosened rock is removed, and the remainder of the holes are then charged and fired in the same way, but only those on one side at a time. When all the holes have been fired, the miner begins again by taking out more sand, and the work goes on until the depth to which the holes have been bored is reached. The drilling machines are then brought from the other shaft, and the holes are again bored from 250 to 300 ft. deeper. No difficulty is found even at a depth of over 1,000 ft. in maintaining a rate of speed in sinking of from 50 to 60 ft. a month, which is 50 per cent. greater speed than has been attained in hand drilling through similar rock in shafts of equal sectional area, which in these shafts is 224 and 364 sq. ft. The greatest depth blasted in one month was 112 ft., and 125 ft. of the shaft was timbered in the same month. The cost per foot is about the same as by hand drilling, but the great advantage of this system is the saving of time, which is a consideration of immense importance in an operation involving the outlay of so much money. By the old system, as only a few men could work at a time in so small a space, the sinking of the shaft was very slow, the large capital invested was unproductive, and the profits to be derived from the mine in active operation were lost.—When it is necessary to put in metal casing or tubing to dam back water, quicksands, or decomposing fire clays, such as are met with in some of the bituminous coal fields at great depths below the surface, the usual method is employed. The casing is taken down the pit in sections and bolted together to form the tube at the bottom; and this may be done below or above the shield. When the surface water has been properly stopped and all the heavy springs dammed back as they are met, the water will not be difficult to manage with buckets, even when great springs or underground watercourses are met with. But when the accumulation of many streams descends to the bottom of the shaft, any great feeder of water might overcome both buckets and pumps. The purpose of such walling, cementing, and tubing is to avoid the use of pumps either during sinking or permanently, because the water can be drained more effectively. This method of damming back the water has not been used in the anthracite mines of Pennsylvania, and rarely if ever in any American pits, most of which are square or oblong, and both sinking and permanent drainage are effected by pumps, at great and constant cost. The best pump for sinking is that known as the Cornish bucket pump, with the column pipe larger than the working barrel, so that both the buckets and the clack valve may be drawn to the surface through the pipes, if necessary for repairs, in case of accident. The pump rods must work inside of the pipes in this plan. This pump may be greatly improved for ordinary permanent lifts by reversing the above order and providing a working barrel of double the capacity of the pipes, and combining the plunger and bucket principle in the working barrel. Thus the down stroke forces one half the water from the barrel, and the up stroke draws the remainder. This is the cheapest, simplest, and most effective style of pump for all purposes, worked from the surface. But most of the large collieries of the world are now drained by the common Cornish plunger or force pump, the principle of which is well known. Some of these are operated by complicated machinery, but the best are those in which the pump rods are connected directly with the steam piston of the engine, without additional gearing. These are used to force water 500 ft. high, but 200 to 250 ft. vertical height is far more economical and safe. Mining pumps of a new and far more effective style have been

introduced during the last 10 or 15 years. They are direct-acting force pumps, but instead of being connected with the engine by rods, the steam is carried in pipes to the bottom of the mine, where both steam cylinder and pump are connected by a very simple arrangement, as a single piece of machinery. The Allison and Bannan pump is generally used where pumps of this class are employed in anthracite mines, while the Cameron pump is used in England and this country for the same purposes. One of these has recently been placed in the mines at Bishop Auckland, England, with a steam cylinder of 26 in. and a pump barrel of 6 in. diameter, with 6 ft. stroke to each. This pump throws a steady stream of 120 gallons per minute up a vertical height of 1,040 ft. in a single lift, under a water pressure of 700 lbs. per square inch. At the close of 1870, 130 of these pumps were at work in the mines near Newcastle and Durham, England.—The raising of coal from deep mines is now almost exclusively done by cages, on the principle of the elevators used in hotels. These cages are moved with the speed of a railroad train. They are provided with "shoes," or projecting guide slots or holes, which move on or in guides of wood,

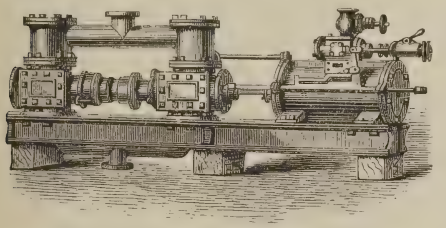

Fig. 18.—Underground Mining Pump.

iron, or rope, extending from the top to the bottom of the pit. These cages are in one or two stories, and carry one or two mine cars on each story. They are provided with rails corresponding to the track both at the bottom and top of the pit. The time occupied in shifting the cars and hoisting through 2,400 ft., in the Rosebridge pits, near Wigan in England, is less than one minute. When the water is properly dammed back there is generally very little in deep pits; and when the mines are dry and dusty, as they very generally are, there is scarcely enough water to moisten the air and allay the dust, if properly distributed over the mines, which however is rarely done. But when the water is in excess, and not very abundant, a tank may be placed beneath the cage, which dips into the water and fills through self-acting valves at the bottom of the pit, and discharges by automatic arrangement at the top. This is simple, cheaper, and better than pumps in very deep mines, when the water is not excessive; but when it is abundant, the pump is the most available. The cages are now generally raised by means of two engines or steam cylinders connected directly, without spur gearing, to the cranks of the drum on which the rope is wound. The engines are connected with link motion, so that one is on the "live centre" or half stroke while the other is on the "dead centre" or full stroke, and are reversed at each ascent and descent of the cages, of which there are always two, one descending while the other is ascending. Round wire or steel ropes are generally used; but there can be no doubt that flat steel ropes are the best for deep pits. These should be made of uniform steel, and composed of several round ropes combined, or served together with steel wire, and very carefully stretched and adjusted before they are put to work. Flat ropes work on or in grooved drums, and lap on themselves. Thus at starting, when the strain on the engines is the hardest, the diameter of the drum is the smallest, and much in favor of the lift; while the descending car and cage, which act as counter-balance, are on the larger diameter of the drum, because on this side the rope has lapped on itself and increased the diameter say two inches at each revolution, so that if the drum or groove was 10 ft. in diameter at starting the cage from the bottom, and the pit 2,000 ft. deep, its diameter would be about 20 ft. when the cage arrived on the top. Another very desirable method of elevating coal or water is the "pneumatic lift," now in general use to supply the new material to the top of blast furnaces, and in a few cases to elevate coal in pits. For very deep pits this seems to be an admirable method, and where a pair of circular pits are used, with brick and cast-iron lining, it is the most economical method, both in regard to first cost and permanent operation. The plan is very simple, but difficult to explain without elaborate engravings. The elevation may be effected by means of suction or compression of the air, as now practised in the pneumatic despatch tubes. This mode of elevating coal or water may be extended to any practicable depth, or perhaps as deep as the English or French and Belgian coal basins descend below the sea level, without complicated machinery, and with perfect safety; while the power employed to raise the material supplies the ventilation, because the entire area of the pits can be used to supply air under pressure or vacuum. Thus compressed air may be used for all underground purposes, except the mere handling and breaking down of the coal, as machinery is successfully used for "undermining," which is the most laborious and costly item in mining bituminous coal; while in anthracite mines drilling holes for blasting is the most laborious part, and this also can be done more effectively and cheaply by machinery. (See Mine.)—The increase of temperature is the only great apparent obstacle to increased depth of pits. According to English experience, the temperature rises 1 degree for every 60 ft. of depth. It appears that the old Kuttenberger pit, in Bohemia, was abandoned at 3,778 ft. on account of the high temperature at that depth:

but this pit was sunk before the invention of gunpowder, when blasting was performed with lime, or the rocks were cut with picks and gads or "feather and wedges," and when mining science had made little progress and the best methods of ventilation were not understood. A Belgian coal pit has been sunk 3,411 ft., and one of the largest English collieries is in successful operation at 2,445 ft. The dangers, diseases, and hardships of the collier's life are not the result of deep mining, but of the rude and barbarous character of the mines, and the system of working. Even at the present day nine tenths of the mines of the world, whether of coal or of metals, are not only dangerously imperfect, but unworthy the scientific attainments of the age. In mines which are provided with proper means of ingress and egress, and are well ventilated and drained, the collier's employment is not remarkably dangerous or unhealthy; but this is the exception and the reverse is the rule. The following table of comparisons shows the relative economy of production, and the ratio of danger between the different systems of mining during a period of three years ending 1869:

DISTRICTS.	SYSTEM OF MINING.	No. of tons raised per death from explosions by gas.	No. of deaths from explosions of gas.	No. of deaths in three years.	No. of tons of coal raised per death from underground accidents.	No. of tons raised per death from all causes.	Ratio of safety from explosions of gas.	Ratio of safety from underground accidents.	Tons of coal per capita per annum.
1. Northumberland, Durham, and Cumberland, England	Bord and pillar	4,738,471	7	249	352,863	133,310	100·00	67·98	387
2. South Durham	Bord and pillar	1,522,400	30	279	519,000	163,698	32·12	100·00	387

13. Schuylkill Regions, Pa. (one year, 1871)	Breast and pillar	200,000	25	101	55,000	50,000	5·00	10·00	250

The production of coal in Great Britain during 1871 was 117,439,251 tons, by 370,881 men and boys. In producing this large amount there were 826 accidents and 1,075 deaths; and 109,246 tons of coal were raised for each death, and one life lost to every 345 persons employed.

TABLE OF ACCIDENTS AND DEATHS IN THE BRITISH MINES FOR TWO YEARS.

CAUSE.	ACCIDENTS.		DEATHS.	
	1870.	1871.	1870.	1871.
Explosions of gas	56	52	185	269
Falls of coal, rock, &c.	402	426	411	435
Ascending and descending pits	37	39	47	41
Accidents about pits	81	79	82	82
Miscellaneous underground accidents, explosions of powder, &c.	174	161	186	176
Miscellaneous surface accidents	80	69	80	72
Total	830	826	991	1,075

In the anthracite mines of Pennsylvania the number of deaths from all kinds of mining accidents during 1871 was 274, and the number of tons of coal mined per death 64,500. There were 52,227 men and boys employed in and about the mines, and one life was lost for every 190 employed. This great excess of fatality in the Pennsylvania anthracite regions is partly owing to the large size of the coal beds; but the chief defect is in the bad system of mining, and recklessness in regard to life. In South Wales (No. 10 of the preceding table) similar methods are employed and similar results observed, though the coal beds are not much if any larger than those of the Newcastle district (No. 1), and not as thick as the coal beds of Scotland (Nos. 11 and 12). Where the longwall and bord and pillar systems of mining are used, the best results are obtained; and where the post and stall and breast and pillar methods are in use, the worst results follow; though in the Staffordshire districts, where iron ores and fire clays or the thick coals are mined, the dangers are greatly increased, whatever system is used. There are no data for comparing the mining casualties of the present with those of the past, in proportion to the number of employees or the annual production; but it is gratifying to observe that the ratio of deaths and accidents is constantly diminishing at the collieries of the great producing districts, notwithstanding that the mines are constantly becoming deeper. Moreover, the many causes of disease incident to the older mining communities, resulting from defective ventilation and the poisonous vapors of the mines, carbonic acid (black damp), carbonic oxide (sweet or white damp), sulphurous acid (powder, smoke, &c.), soot, dust, and a general deficiency of pure air, are gradually disappearing.—The pay of colliers differs so greatly that it is not possible to give any regular price. In the anthracite regions laborers in 1871 were

paid from $9 to $11 a week, and miners from $12 to $15; but most of the latter work by contract, and earn from $15 to $20 a week, and sometimes $100 a month, and the cost of coal then ready for market, exclusive of royalty, is about $2 a ton; but the wages have been as low as $4 50 a week for laborers and $6 for miners, and the cost of coal less than $1 a ton. At the English mines, miners' wages are even now much lower than at American mines, though nearly double the rates of ten years ago. The average cost of Newcastle coal during 20 years, on top of the pit, was 2*s.* 8½*d.*, and on board at Newcastle, 5*s.* 6*d.*, made up as follows: rent or royalty, 6*d.*; delivered in cars, 2*s.* 8½*d.*; freight, 1*s.* 6*d.*; interest, 10*d.* In Yorkshire, Staffordshire, Lancashire, Scotland, and Wales the average cost of bituminous coal was 5*s.* 8*d.* during 1845, but during 1871 twice as much. During 1850 the number of the employees, men, boys, women, and girls, in the Belgian mines, and their wages, were as follows:

EMPLOYEES.	No. below ground.	No. above ground.	Wages in frs. above ground.	Wages in frs. below ground.
Men	28,471	7,531	1·70	1·74
Boys	4,464	1,075	0·65	0·94
Women	2,274	1,771	·92	1·30
Girls	1,221	1,142	·56	·85

The great advance in the price of coal in England during 1871, 1872, and 1873 is largely due to the greater demand for both coal and iron, and the decrease in the hours of labor and increase of the wages of miners. The increase of collieries, and the use of machinery in mining coal, will without doubt eventually reduce the price of coal even below its former rate, without reducing the prices of labor to the mere pittance formerly paid in England, and still paid in France and Belgium, for underground work.

COLLIN, a N. E. county of Texas, watered by the E. fork of Trinity river and its tributaries; area, 870 sq. m.; pop. in 1870, 14,013, of whom 1,653 were colored. About two thirds of the county is prairie, the rest timbered. Farming and stock raising are about equally pursued. The chief productions in 1870 were 42,827 bushels of wheat, 674,565 of Indian corn, 123,325 of oats, 32,159 of sweet potatoes, 204,915 lbs. of butter, and 4,371 bales of cotton. There were 10,668 horses, 1,582 mules and asses, 5,065 milch cows, 15,360 other cattle, 4,812 sheep, and 15,550 swine. Capital, McKinney.

COLLIN. See Kolin.

COLLINGWOOD, a town of Simcoe co., Ontario, Canada, on the S. shore of Georgian bay, 72 m. N. W. of Toronto; pop. in 1871, 2,829. It derives its importance from being the northern terminus of the Northern railway, whence steamers connect with the N. shore and with ports on Lake Superior. Two lines of steamers ply between here and Lake Superior.

COLLINGWOOD, a suburb of Melbourne, Australia, situated on low ground between that city and the Yarra Yarra to the northeast; pop. about 19,000. It is almost a town of itself, having a council chamber, banks, numerous churches and public buildings, and many manufactories.

COLLINGWOOD, Cuthbert, lord, an English admiral, son of a merchant of Newcastle-on-Tyne, born there, Sept. 26, 1750, died March 7, 1810. He went to sea at the age of 11, as midshipman under Capt. Brathwaite. After some years afloat he made a cruise under Admiral Roddam, and thence was transferred to Graves's fleet acting against the Americans, reaching Boston in 1774. On the day of the battle of Bunker hill he was appointed fourth lieutenant of the Somerset, and placed in charge of a party of marines who kept open communication between the troops and the ships. Next year he was given command of the sloop Hornet, with which he went to Jamaica, where he renewed acquaintance with Horatio Nelson, then lieutenant of the Lowestoffe, whom he had known in boyhood. The career of these eminent men was closely united during the rest of their lives. In 1780 Nelson, being in command of the Hinchinbroke, was ordered to conduct a boat expedition to the Pacific along the San Juan river and Lakes Nicaragua and Leon. He was prostrated by fever and sent home, and Collingwood took his place. His robust constitution carried him through, but he buried 180 of his 200 men. The expedition was found impracticable. In the succeeding year he was wrecked in the Pelican, 24 guns, on Morant keys, West Indies. Thereafter he was transferred to the Samson, 74, in which he served till the peace, and in 1783 was sent with the frigate Mediator to reënforce the squadron employed in preventing the Americans from trading with the West India islands. On his release from that duty in 1786, he revisited his home at Newcastle, after an absence of 25 years. On the breaking out of the war with the French, he served on board the Barfleur, which bore a conspicuous part in Lord Howe's victory, June 1, 1794. In 1797 he was placed in command of the Excellent, 74, which he fought with effect in Jervis's victory off Cape St. Vincent, Feb. 14. When Nelson heard that the Excellent was coming to reënforce him, he exclaimed: "That counts two!" In 1799 he was made rear admiral of the white; in 1801, admiral of the red; and in 1804, of the blue. He was detailed in 1803 to watch the French fleet off Brest, which he did for nearly two years. His crowning achievement was at Trafalgar, Oct. 21, 1805, where he was second in command, and when Nelson fell took the chief command and finished the day. For this service he received the thanks of parliament, with a peerage, and a pension for his family of £2,000. His subsequent career was a succession of semi-political missions to the Mediterranean, which taxed his endurance and skill

to the utmost. He repeatedly requested leave to retire, but the government informed him that they could not spare his services. Worn out at length, he died at sea while cruising off Minorca. His remains were brought home and deposited in St. Paul's cathedral, near Nelson's. Selections from his despatches and correspondence were published at London in 1828, by G. L. N. Collingwood.

COLLINS, Anthony, an English philosophical and skeptical writer, born at Heston, Middlesex, June 21, 1676, died in London, Dec. 13, 1729. He was educated at Eton and at King's college, Cambridge, and was afterward entered a student in the Temple at London, but applied himself chiefly to literary studies. In 1703 he began a correspondence with Locke, who cherished an enthusiastic affection for him, admiring in him "as much of the love of truth for truth's sake as ever he met with in anybody." In 1707 he published a treatise concerning the use of reason in propositions depending on human testimony, and in the same year engaged in the controversy between Dodwell and Dr. Samuel Clarke concerning the natural immortality of the soul. In 1709 he published "Priestcraft in Perfection," assailing the 20th article of the church of England, which affirms the power of the church to decree rites and ceremonies and to determine controversies of faith. Numerous answers were written to this work, the most noted of which was by Dr. Bennet, to which Collins replied in his "Essay on the Thirty-nine Articles." He advocated the necessitarian scheme in his "Vindication of the Divine Attributes" (1710), which views he developed more fully in his "Philosophical Inquiry concerning Liberty and Necessity" (1715). Though he endeavors to prove that man is a necessary agent morally as a clock is physically, he yet does not deny the power in man of doing as he wills and pleases; and in several of his views he anticipated Jonathan Edwards, the ablest subsequent champion of necessity. In answer to his opinions Dr. Clarke published in a tract one of the most important of his metaphysical arguments. In 1711 Collins resided in Holland, where in the society of Le Clerc and others he matured his "Discourse on Free Thinking," which was published on his return in 1713, and excited much animadversion. Its aim was to show that in all ages the most intellectual men and most admirable characters have been free thinkers, relying rather on philosophical thought than established opinion. The most remarkable of the numerous answers to it were by Bentley in England and Crousaz in France. In 1718 he became treasurer of the county of Essex, and soon after published his "Grounds and Reasons of the Christian Religion," maintaining that though Christianity is founded upon Judaism, and the assertions of the New Testament are proved in part by propositions from the Old, yet there is nothing in the latter which has a direct or other than a typical or allegorical bearing upon anything in the former. Within two years 35 answers appeared to this work, among others, by Whiston and Drs. Clarke, Sykes, and Sherlock; to which Collins replied finally in his "Scheme of Literal Prophecy." His last work was written in 1727, in reply to eight sermons by Dr. Rogers on the necessity of a divine revelation. Collins was a subtle and ingenious rather than a profound writer. His personal amiability was remarked even by his opponents, and his large and very curious library was open to all men of letters.

COLLINS, Charles Allston, an English painter and author, brother of Wilkie Collins, born at Hampstead, Jan. 25, 1828, died in London, April 9, 1873. From 1848 to 1858 he was engaged in painting, and exhibited several pictures at the royal academy and elsewhere, which attracted attention. Afterward he devoted himself to literature. Among his works are: "A Cruise upon Wheels" (1862), a humorous account of a journey in France; "Strathcairn" (1864); and "At the Bar" (1866). He married a daughter of Charles Dickens.

COLLINS, Isaac, an American printer and publisher, born in Delaware, Feb. 16, 1746, died at Burlington, N. J., March 21, 1817. His father emigrated to the United States from Bristol, England. Collins served an apprenticeship to the printing business, and at its completion went to Philadelphia, where he worked 18 months as a journeyman, and then went into partnership with Joseph Cruikshanks. In 1770 he removed to Burlington, having been chosen colonial printer to George III. Here he married and became the father of 14 children. In 1771 he commenced printing an almanac, and continued it for 20 years. He was also at this time the publisher of several other works. Removing to Trenton, N. J., in 1778, he projected what was in the publishing business of that time a great enterprise, namely, the publication of an octavo family Bible. In order to secure the utmost accuracy in typography, the whole was subjected to 11 proof-readings, the last of which was by his daughter Rebecca. So free from errors was this edition of the Scriptures, that it became at once the standard for all critical appeal, when the English translation alone was concerned.

COLLINS, William, an English poet, born at Chichester, Dec. 25, 1720, died there, June 12, 1756. He was destined for the church, and in 1733 was admitted a scholar at Winchester. In 1740 he stood first in the list of scholars to be entered at New college, Oxford, but no vacancy occurred, and this circumstance Dr. Johnson calls the original misfortune of his life. He became a commoner of Queen's college, whence he was transferred to Magdalen. While at Winchester school he had written his "Eclogues," which he printed in 1742. They appeared without his name, and attracted little notice. He took his bachelor's degree at Oxford in 1744, and soon left the university abruptly, repairing to London as a literary ad-

venturer. Having no fixed purpose, little perseverance, and withal great impatience for distinction, he was for several years engaged in drawing up proposals for works which were never written, and destroying what little he wrote. He was much annoyed also by duns, and was at one time in the hands of bailiffs. He borrowed some money from a bookseller as an advance on a projected translation of Aristotle's Poetics; but having inherited about £2,000 from his uncle, Col. Martin, he repaid the publisher and thought no more of the translation. In 1746 he published his odes. He was much disappointed in the reception of his productions, and died probably with little idea of the celebrity they were to attain. The latter part of his life was passed in a state of insanity, with only occasional lucid periods, and for some time he was confined in a lunatic asylum.

COLLINS, William, an English painter, born in London, Sept. 18, 1787, died Feb. 17, 1847. His earliest ideas in painting were derived from watching the process by which Morland executed his animal pieces. In 1807 he studied at the royal academy, and from that time until his death, with the exception of two years spent in Italy, never omitted to send pictures to the annual exhibitions. In 1820 he was elected an academician. In 1836 he went to Italy, and on his return made an unsuccessful appearance at the academy exhibitions as a historical painter. Many of his pictures have been engraved, as "Prawn Fishers at Hastings," "Happy as a King," the "Shrimpers—Evening," the "Fisherman's Widow," &c.

COLLINS, William Wilkie, an English novelist, son of the preceding, born in London in January, 1824. After being educated at a private school, and spending two years with his parents in Italy, he was articled for four years to a firm in the tea trade. Exchanging commerce for law, he was a student in Lincoln's Inn at the time of his father's death; and his first literary performance was an admirable biography of him, with selections from his journals and correspondence (1848). He devoted himself from this time entirely to literature, and published successively, between 1850 and 1854, "Antonina, or the Fall of Rome," "Rambles beyond Railways, or Notes in Cornwall," "Basil," "Mr. Wray's Cash Box," and "Hide and Seek." He soon after became a contributor to "Household Words." All his later novels originally appeared as serials in periodicals. The principal of them are: "After Dark" (1856), "The Dead Secret" (1857), "The Queen of Hearts" (1859), "The Woman in White" (1860), "No Name" (1862), "Armadale" (1866), "The Moonstone" (1868), "Man and Wife" (1870), "Poor Miss Finch" (1872), and "The New Magdalen" (1873). In 1863 appeared "My Miscellanies" (2 vols.), made up of contributions to journals. He has also written three dramas, "The Frozen Deep," "The Lighthouse," and "Black and White." At the end of 1873 he visited the United States, where he gave public readings from his works in the principal cities.

COLLINSON, Peter, an English botanist, born at Hugall Hall, Westmoreland, Jan. 14, 1693, died Aug. 11, 1768. He was a member of the society of Friends, and a merchant in London. His studies in natural history gained him the acquaintance and correspondence of the most eminent naturalists of his time. He corresponded with Cadwallader Colden and Franklin, and is said to have made known to the latter (1743) the first experiments in electricity, and sent to him the first electrical machine that went to the colonies. He gave special attention to botany, and to the naturalization of plants and trees in regions remote from their original habitats. He sent to Maryland, Pennsylvania, and other Atlantic colonies, many foreign ornamental shrubs, which found in America a congenial soil and climate; and he introduced into England many American forest trees. He was one of the first to suggest the culture of the grape in Virginia. A genus of labiate plants is named *Collinsonia* after him. He was also familiar with the antiquities of England, and read many interesting papers before the society of antiquaries.

CÖLLN, Georg Friedrich Wilibald Ferdinand von, a German author, born at Oerlinghausen, Lippe-Detmold, in 1766, died in Berlin, Jan. 13, 1820. He held various offices in different places, and was for a time editor of the *Staats-Anzeiger* in Berlin, but in 1808 was imprisoned in the fortress of Glatz on account of damaging disclosures of maladministration made in some of his books. In 1810 he was permitted to visit a watering place, whereupon he fled to Austria. The king of Prussia subsequently pardoned him, and he was even pensioned and employed in the public service. His works were chiefly anonymous. Among them are: *Neue Feuerbrände* (6 vols., Leipsic, 1807–'8); *Wien und Berlin in Parallele* (5 vols., 1808); *Vertraute Briefe über die innern Verhältnisse am preussischen Hofe* (3 vols., Amsterdam and Cologne, 1807–'9); *Die neue Staatswissenschaft* (2d ed., Berlin, 1816); and *Historisches Archiv der preussischen Provinzialverfassungen* (1819–'20).

COLLODION, or **Collodium** (Gr. κόλλα, glue, and εἶδος, form), an adhesive substance produced by dissolving gun cotton in ether and alcohol. The proportions recommended are, prepared cotton 8 parts by weight, rectified ether 125 parts, and rectified alcohol 8 parts. The presence of water in the alcohol and ether should be carefully avoided. The cotton is to be agitated in a bottle with the ether a few minutes, when the alcohol may be added, and the shaking continued. The product, a clear, colorless liquid, of the consistency of sirup, is next strained through a cloth, and the liquid kept in a tight bottle. It is very volatile, and on evaporating leaves a film which adheres with extraordinary tenacity to the surface of bodies. This property makes it a convenient

application to cuts and wounds in the place of sticking plaster, either by brushing it alone over the edges of the incision, or by spreading it upon strips of linen. It was first applied to this use by Dr. J. Parker Maynard, of Boston, to whom the name was suggested in 1848 by Dr. A. A. Gould. Collodion is best prepared from gun cotton made by the process of Prof. Ellet. Gun cotton made by steeping the fibre in nitric acid does not always dissolve in ether and alcohol. Prof. Ellet's, being always soluble, is preferred for this purpose, prepared as follows: 8½ fluid oz. of sulphuric acid are added to 10 oz. of nitrate of potassa, mixed, and triturated in a mortar; ½ oz. of fine clean cotton is then thoroughly stirred into the mixture for about four minutes; the free acid is next removed by washing in water till all traces of it disappear. The gun cotton, being opened by picking and dried at a gentle heat, is dissolved in 2½ pints of ether already mixed with a fluid ounce of alcohol. The solution is to be strained, and kept in closely stopped bottles previously well dried. A similar method is given by Lauras, and the cotton, which he calls *xyloidin*, produces by his process a quality of collodion possessing elasticity and suppleness, which adapt it for application to the skin, especially on the articulations where freedom of motion is an important object. To a mixture of 300 grms. of sulphuric acid of sp. gr. 1·847, and 200 grms. of dry nitrate of potassa, he adds 10 grms. of carded cotton. After being in contact 12 minutes the cotton is taken out and washed with cold water, rinsing it two or three times. It is then immersed in a solution of 30 grms. of carbonate of potassa to 100 of water, again well washed with water, and dried at 77° to 86° F. Of this xyloidin 8 grms. are placed in a flask with 125 of ordinary ether, and 8 grms. of alcohol are added of sp. gr. ·825. The mixture is well agitated and then combined with a preparation of Venice turpentine 2 grms., castor oil 2 grms., and white wax 2 grms., to which, after being heated, 6 grms. of ether should be added.—Collodion was first applied to photographic purposes in 1847, by Mr. Archer of England. It is used as a menstruum for affixing to a glass plate a film of some iodide, as of potassium, ammonia, or cadmium, a solution of which is mixed with it.—Collodion is used in medicine exclusively as an external application. Besides its use as an adhesive application to slight cuts and wounds, already referred to, it is often applied with decided advantage to sore and cracked nipples and to chapped hands, and used as a protection in some diseases of the skin, especially in chronic erythema, intertrigo, and herpes labialis. Whenever there is acute inflammation of any surface, the contractile action of collodion is apt to produce pain and irritation, and it should not then be used. The annoying bleeding which sometimes follows the cut of a razor while shaving may be instantly stopped by an application of collodion. A mixture of 100 parts of collodion with 2 parts of glycerine makes a more agreeable application than collodion alone, and one equally efficacious. It forms with cantharides a convenient blistering agent. Collodion should be applied with a camel's hair pencil. It may be kept for a long time fit for use in a well stoppered bottle.

COLLOMBET, François Zénon, a French author, born at Siéges, in the department of Jura, March 28, 1808, died in Lyons, Oct. 16, 1853. He studied theology in accordance with the wishes of an uncle, but having inherited some property he turned to literature. He resided at Lyons, where he occupied a single room for 23 years. He wrote for Feller's *Dictionnaire historique*, the *Biographie universelle*, and the *Revue du Lyonnais*. In 1848 he received from the academy of Lyons a prize for an *Éloge de Chateaubriand*. He died from overwork, leaving 40 volumes of writings, including *Cours de littérature profane et sacrée* (4 vols. 8vo); *Histoire de Saint Jérôme* (2 vols., 1844); *Histoire critique de la suppression des Jésuites* (2 vols., 1846); and *Histoire de la Sainte Église de Vienne* (3 vols.).

COLLOREDO, a noble family of Austria, represented also in Italy, a branch of the house of Wallsee or Waldsee, which held the vice-comitat of Mels in 1031, and was divided at the death of During II. in the 13th century into three lines: Mels-Colloredo, Prodolone, and Venzone. The earliest direct ancestor of the house was probably Wilhelm, who built in 1302 the castle of Colloredo in Friuli, near the village of Mels. His three surviving sons, Asquin, Bernhard, and Weickardt, became the founders of three separate branches.—To the Asquin line belong the following prominent names: Rudolph von Colloredo, born Nov. 2, 1585, distinguished himself in the thirty years' war, and especially at the defence of Prague in 1648, as field marshal of the imperial army, and died Jan. 24, 1657. Hieronymus, his brother, born in 1582, served as cavalry general during the same war, and fell in the battle of St. Omer in 1638. The last of this line was Ludwig, son of the last named, who died Dec. 28, 1693, with the rank of feldzeugmeister.—In the Bernhard line the following distinguished themselves: Johann Baptist von Colloredo-Wallsee in 1648 took command of the Venetian forces in Candia against the Turks, and fell during the siege in October, 1649. Franz de Paula, count of Colloredo, born Oct. 29, 1799, was attached to the English legation in 1820, was minister at Copenhagen in 1825, at Dresden in 1830, at Munich in 1836, at St. Petersburg in 1843, again at London in 1852, and subsequently ambassador in Rome; and in 1859, after the preliminaries of Villafranca, he was appointed first plenipotentiary of Austria to negotiate the terms of peace at Zürich, where he suddenly died, Oct. 26, 1859, leaving no issue.—The Weickardt line produced the following prominent men: Fabrizio, a Florentine statesman, born in 1576, was sent as am-

bassador to the emperor Rudolph II. by Cosmo II. de' Medici, whose successor, Ferdinand II., appointed him chief minister of state. He died in 1645. The story of his journey to the Austrian court was written in Latin by Daniel Eremita, and forms an interesting work on the manners of that age. HIERONYMUS, count of Colloredo, born in 1674, was governor of Moravia from 1714 to 1717, was appointed chief marshal of the Austrian court in 1725, and died in 1726. Count RUDOLPH JOSEPH, his son, born July 6, 1706, was for 50 years vice chancellor of the German empire, and died Nov. 1, 1788. His son, JOSEPH MARIA, count of Colloredo-Mels and Waldsee, born Sept. 11, 1735, distinguished himself in the seven years' war, was appointed lieutenant field marshal and councillor of war, and accompanied the emperor Joseph II. to France. On his return to Austria he was intrusted with the general direction of the artillery, and soon after he was made feldzeugmeister. He participated in the Turkish war, and was made field marshal and commander-in-chief of the army of observation on the Prussian frontier. From 1805 to 1809 he was minister of state and conference, and director of the council of war. He died Nov. 26, 1818. Count WENZEL JOSEPH VON COLLOREDO, born Oct. 15, 1738, brother of the preceding, participated in the seven years' war, was made lieutenant field marshal in 1784, feldzeugmeister during the Turkish war, and field marshal in 1808. He died Sept. 4, 1822.—COLLOREDO-MANSFELD has been since 1771 the name of the princely branch of the house, forming a part of the Weickardt line, of which the following are to be noted: FRANZ DE PAULA GUNDACCAR, prince of Colloredo-Mansfeld, born May 28, 1731, married the countess of Mansfeld, and added her name to his own. He was ambassador at Madrid from 1767 to 1771, and vice chancellor of the German empire from 1789 to 1806. He died Oct. 7, 1807. FERDINAND, count of Colloredo-Mansfeld, born in Vienna, July 30, 1777, was in 1801 ambassador at Ratisbon, in 1803 at Naples, and in 1806 at Palermo. He fought valiantly in the battles of Aspern and Wagram in 1809, and rendered valuable assistance in the organization of the landwehr. He retired to his estates in 1815, whence he issued during the revolution of 1848 to take command of the academical legion. He died in the same year. HIERONYMUS, count of Colloredo-Mansfeld, born in 1775, took part in nearly all the campaigns of his time, and distinguished himself Aug. 30, 1813, in the battle at Culm, where Russia and Austria have jointly erected a monument to his memory. At the battle of Leipsic, having previously obtained the rank of feldzeugmeister, he took the chief command in place of the prince of Homburg, who had been wounded. He died in Vienna, July 23, 1822, from the effect of his wounds. FRANZ DE PAULA GUNDACCAR, prince of Colloredo-Mansfeld, son of the preceding, born in Vienna, Nov. 8, 1802, was rapidly promoted, and commanded in 1848 as major general in Trieste and Theresienstadt. He distinguished himself in the Hungarian war at Kápolna and Comorn, and obtained the chief command of an army corps. He died May 29, 1852. JOSEPH FRANZ HIERONYMUS, prince of Colloredo-Mansfeld, cousin and heir of the preceding, was born Feb. 26, 1813. He is a hereditary member of the upper house in the Austrian diet. His eldest son, Count HIERONYMUS, born July 20, 1842, took part in the Schleswig-Holstein war of 1864, and married in 1865 the countess of Festetics-Tolna.

COLLOT D'HERBOIS, Jean Marie, a French revolutionist, born in Paris about 1750, died in Cayenne, Jan. 8, 1796. His name was originally Collot, but having become an actor he adopted the additional name of d'Herbois. He appeared upon the stage for many years, and was the author of a large number of plays, some of which had considerable success. When the revolution broke out he joined the Jacobins at Paris, and acquired great influence by his sonorous voice, theatrical attitudes, and impulsive elocution. He was particularly energetic in his efforts to procure the release of a body of soldiers who had been imprisoned for having taken part in an insurrection at Nancy. After having been released they entered Paris in a grand procession, in which a conspicuous place was assigned to Collot. He also obtained the prize offered by the Jacobin club for the best almanac for 1792, which should make the advantages of constitutional government understood by the people. His work, called the *Almanach du père Gérard*, brought him great celebrity. He presided over an assembly held for the nomination of deputies to the convention, was himself elected a member, and in that capacity favored the most violent measures. He was chosen president of the convention, June 13, 1793, and in September of the same year he was placed with Billaud-Varennes upon the committee of public safety. In November Collot was sent with Fouché and Couthon to Lyons to punish the city for an insurrection. This was done by the slaughtering of the inhabitants *en masse* with grape shot, and the demolition of the buildings. When he returned to Paris he found that odium had been created against him by his proceedings at Lyons. His popularity was in some measure restored by an attempt to assassinate him, May 23, 1794. From a supporter of Robespierre he now, however, became his opponent; but the reaction proved too strong for him. He was removed from the committee of public safety, and, being found guilty of some of the charges brought against him, was transported to Cayenne.

COLLYER, Robert. See supplement.

COLMAN, Benjamin, an American clergyman, born in Boston, Oct. 19, 1673, died there, Aug. 29, 1747. In 1692 he graduated at Harvard college, and not long afterward began to preach. He embarked for England in 1695,

but the vessel in which he sailed was captured by a French privateer, and he was carried to France as a prisoner. Being exchanged soon after, he passed over to England, where he remained till 1699, preaching in different places. In that year, having accepted an invitation to become pastor of a society just formed in Brattle street, Boston, he returned to America and entered upon his new duties. Of this society he remained pastor until his death. In 1724 he was chosen president of Harvard college, which office he however declined, and in 1731 he received the degree of D. D. from the university of Glasgow. He published many sermons, some poems, and a tract in favor of inoculation for the smallpox.

COLMAN. I. George, the elder, an English comic dramatist, born in Florence about 1733, died at Paddington, Aug. 14, 1794. His father was British resident at the court of the grand duke of Tuscany. After receiving his early education at Westminster school, he became a student at Christchurch college, Oxford. He acquired a reputation for wit and talent, and published a weekly periodical called the "Connoisseur," from January, 1754, to September, 1756, which delineated the manners of the time with admirable humor. He studied law at Lincoln's Inn, and was admitted to the bar, but devoted himself to dramatic pursuits, writing "Polly Honeycomb" and "The Jealous Wife." At the death of his uncle, Lord Bath, he came into possession of a handsome fortune. In 1766 he joined with Garrick in writing "The Clandestine Marriage," and in 1767 he became part owner of Covent Garden theatre, and was acting manager of it for seven years. In 1777 he purchased the Haymarket theatre, which he supplied with pieces either original or translated. He was the author of more than 30 dramatic pieces, a few of which still keep possession of the stage. He was also a classical scholar, and made a translation of the comedies of Terence, and of Horace's "Art of Poetry." A paralytic stroke in 1790 resulted in his mental derangement, and he was removed to a lunatic asylum at Paddington. His "Dramatic Works" were published in 1777 (4 vols. 8vo), and his "Miscellaneous Works" in 1787 (3 vols. 12mo). **II. George,** the younger, son of the preceding, born Oct. 21, 1762, died Oct. 26, 1836. In 1785, in consequence of the illness of his father, he assumed the management of the Haymarket theatre, and retained it for a long time. In the latter part of his life he held the office of examiner of plays. He was distinguished as a wit, and divided with Sheridan the admiration of the London circles. He wrote "John Bull," "The Iron Chest," and "The Poor Gentleman," which still retain their popularity. He also wrote "Broad Grins," "Poetical Vagaries," &c., and various small poems.

COLMAN, Henry, an American clergyman and author, born in Boston, Sept. 12, 1785, died in London, Aug. 14, 1849. He graduated at Dartmouth college in 1805, and was ordained minister of a Congregational church at Hingham, Mass., in 1807, remaining there till 1820. From 1825 to 1831 he officiated as pastor of a Unitarian society in Salem, and afterward removed to Deerfield, where he devoted himself to agricultural pursuits. He was appointed agricultural commissioner of the state of Massachusetts, and after passing some time in making a tour of inspection in that state, and in preparing several reports, he spent six years, from 1842 to 1848, in Europe. The results of his observations during this time were published after his return in his "Agricultural and Rural Economy of France, Belgium, Holland, and Switzerland," "European Agriculture and Rural Economy," and "European Life and Manners, in Letters to Friends." He also published a report on silk culture and reports on the agriculture of Massachusetts. In 1849 he revisited Europe, for the benefit of his health, but died soon after his arrival in England.

COLMAR (under the Franks *Columbaria*), a city of Germany, capital of Upper Alsace, (formerly of the French department of Haut-Rhin), 40 m. S. S. W. of Strasburg; pop. in 1872, 23,045. It is situated near the foot of the Vosges mountains, on the Lauch and Fecht rivers, both tributaries of the Ill, a feeder of the Rhine, and on the railway from Strasburg to Basel. Colmar is one of the chief seats of cotton manufacture in Germany, and possesses also various other manufactures. The principal factory for cotton prints employs about 1,200 persons. It has normal schools for teachers, a gymnasium, a public library with 60,000 volumes, a Bible and a literary society, a civil and military hospital, a theatre, a Protestant church, several Catholic churches, and Jewish synagogues. The cathedral is a Gothic edifice of the 14th century, containing a remarkable painting of Martin Schön, who was a native of Colmar. Gen. Rapp was also born there, and a monument has been erected to his memory. Colmar was made a free imperial city in the 13th century, figured conspicuously in the civil wars under Rudolph of Hapsburg and Adolphus of Nassau, was taken by the Swedes in 1632, and later by the French, returned for a time to Germany, but was retaken by Louis XIV., and annexed to France in 1697 by the treaty of Ryswick. In 1871 it was ceded with the rest of Alsace to Germany.

COLNE, a market town of Lancashire, England, on the Colne, an affluent of the Calder, 26 m. N. of Manchester; pop. about 8,000. It is one of the most ancient seats of woollen manufacture in England; but since the introduction of the cotton manufacture, toward the close of last century, the population has been chiefly employed in producing cotton goods for the Manchester market.

COLOCOLO (*felis ferox*), a large cat of the size of the ocelot, living in the northern parts of South America. The color is grayish above, white below, with black longitudinal streaks

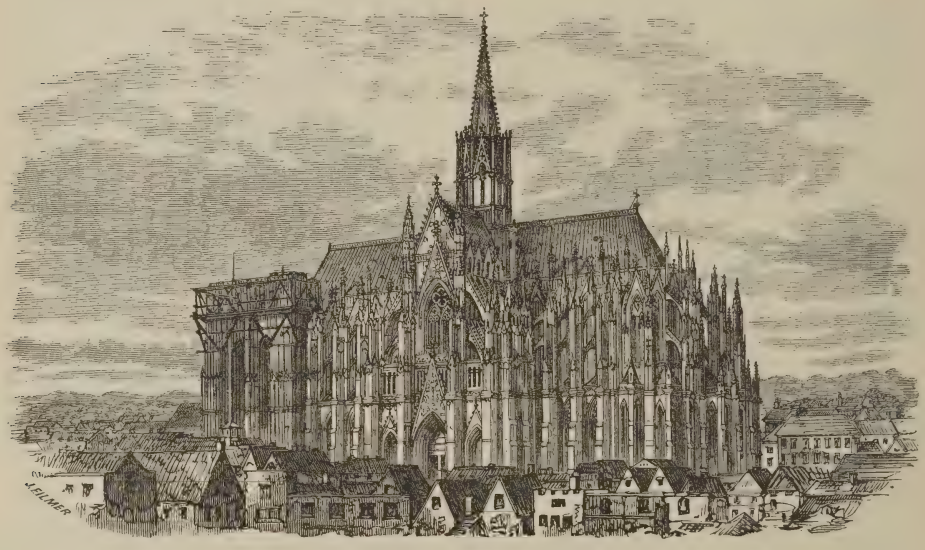
on the body and limbs, and the tail with partial black rings, the stripes edged with tawny. It is very savage, and commits great havoc among the monkeys and small mammals of

Colocolo.

Guiana. In its flat and wide head, large rounded ears, stout limbs, and short tail it somewhat resembles the African serval.

COLOCOTRONIS, Theodoros, a modern Greek general, born in Messenia, April 3, 1770, died in Athens, Feb. 4, 1843. His father and grandfather both fell fighting against the Turks, and Theodoros was habituated from his youth to the hardships of guerilla warfare. In 1806 he was compelled to fly from the Morea in order to escape the Turks, to whom his name had become a terror, and entered the military service of the Ionian Islands. Immediately on the outbreak of the revolution in 1821 he landed in the Morea, and was soon at the head of a large band of Greeks. In the two following years he was actively engaged in the operations against the Turks, distinguished himself especially at the taking of Tripolitza and Corinth, and contributed greatly to the victory over Mahmoud Dramali in 1822. But instead of bending all his energies toward the achievement of Grecian independence, he engaged in quarrels with his brother chiefs, and at last made open war upon the recognized government. He was unsuccessful in his revolt, however, and, having been defeated and taken prisoner, was confined on the island of Hydra. But the Grecian leaders were soon compelled to liberate him, and to place him at the head of affairs in the Morea, in order to satisfy the people of that part of Greece, among whom he was very popular, and to oppose the progress of Ibrahim Pasha. In 1827 he assisted to elect Capo d'Istria president of Greece, and was afterward confirmed by him in his command of the Morea. He was a member of the provisional government established after the assassination of that statesman in 1831. Opposed to the regency which was established during the minority of Otho, and detected in a conspiracy against that government, he was condemned to death in April, 1834. His punishment was, however, in consideration of the valuable services he had rendered the state, commuted to imprisonment for 20 years in the citadel of Nauplia; and Otho on his being declared of age in the following year granted him a full pardon, restored him to his old rank as general, and bestowed on him the decoration of the order of the Saviour. From this time until his death he lived quietly at Athens, where he composed his "Memorabilia" relating to the history of Greece from 1770 to 1836, which were published at Athens in 1851.

COLOCYNTH, the fruit of *citrullus colocynthis*, a plant of the order *cucurbitaceæ*, somewhat resembling a small watermelon, and growing in various parts of Asia and Africa. The pulp of the fruit, deprived of rind and seeds, is intensely bitter and powerfully cathartic. These properties are due to colocynthine, a neutral bitter substance existing in the dried pulp in the proportion of about 14 per cent. Colocynth is used in medicine chiefly in the form of compound extract, in which it is combined with aloes, scammony,



Colocynth.

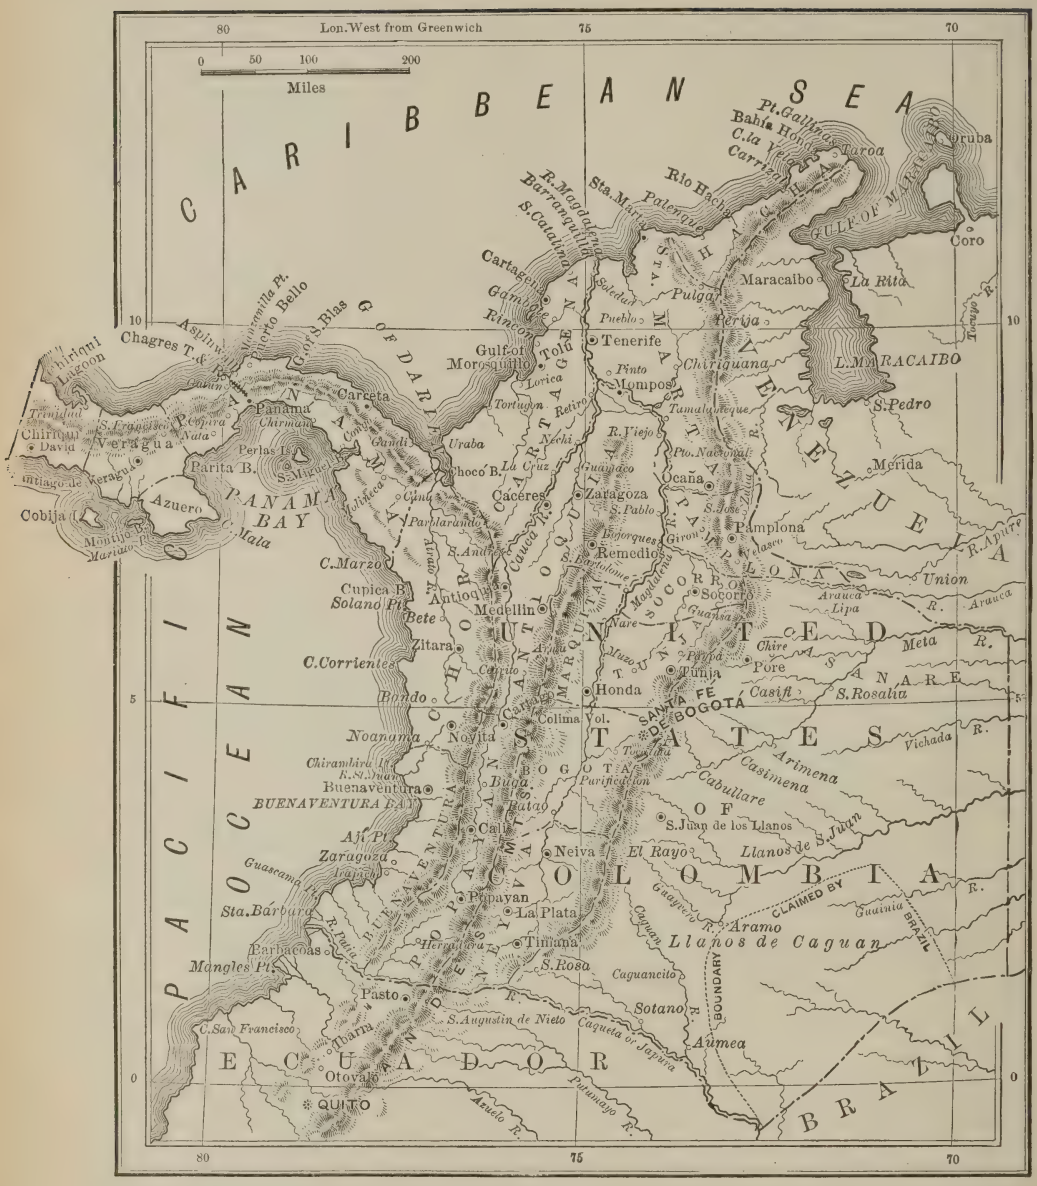
cardamom, and soap. This combination renders its action milder, but not less efficacious. It is still further combined with calomel, jalap, and gamboge, in the compound cathartic pill. A tincture is used in Germany. The unripe fruit is said to be eatable when pickled. A hybrid between the colocynth and the watermelon has been produced in this country, which possesses the bitterness and purgative properties of the former.

COLOGNE (German, *Köln*), a city of Prussia, capital of the province of the Rhine and of a district of the same name, situated on the left bank of the Rhine, in lat. 50° 58′ N., lon. 7° E., 38 m. E. N. E. of Aix-la-Chapelle; pop. in 1871, 129,233, mostly Roman Catholics. The suburb of Deutz, upon the opposite bank of the Rhine, is connected with it by a bridge of boats and by an iron railway bridge 1,352 ft. long. The city forms a semicircle which rests upon the Rhine, and is surrounded by strong

walls and protected by forts. Most of the streets are narrow and crooked. Of the public places the finest are the Heumarkt, Waid, Altmarkt, and Neumarkt. The city is the seat of courts of appeal, and of an archbishopric founded in the 8th century. The most noted manufacture is that of eau de Cologne, for the production of which there are 24 establishments. Among the other manufactures are silk and cotton goods, machines, tobacco, lace, paper, wax, soap, and musical and optical instruments. The Rathhaus or town hall has a Gothic tower and a marble porch in the renaissance style. It contains the Hansa-Saal, in which the Hanseatic merchants held their meetings. Another fine building is the Kaufhaus, also called the Gürzenich, from the person who gave the ground upon which it stands. In the hall on the first floor diets of the empire have been held and emperors entertained. It is now used for balls, concerts, &c. The Templars' house is now used for an exchange. The buildings for the government offices, the court of appeals, and the archbishop's palace are all handsome. But the most remarkable building is the cathedral, commenced about 1250, but still unfinished. It is 511 ft. in length, 231 in breadth, and the towers when completed will be 511 ft. high. It is said to be the largest specimen of Gothic architecture in the world. (See CATHEDRAL.) The repair of the building was commenced in 1830 under King Frederick William III., and its construction was carried forward under Frederick William IV. Large sums were appropriated by the government, and money was also raised by private subscription, and by an association called the *Dombauverein*, with branches throughout Eu-

Cologne Cathedral in its present condition.

rope. The nave, aisles, and transept were consecrated in 1848, and the whole interior was thrown open in 1863. The portals, after designs by Zwirner, are finished; the one facing toward the south is greatly admired. Cologne has many other beautiful churches, of which those of St. Gereon, St. Peter, St. Cunibert, St. Ursula, and those of the Jesuits and of the Apostles are the finest. It has also a handsome synagogue, in the oriental style, for the construction of which the banker Oppenheim furnished the funds and Zwirner the designs. The Wallraf-Richartz museum was built by Richartz to contain a large collection of paintings bequeathed to the city by Wallraf. The university of Cologne, famous in the middle ages, no longer exists. There is a public library of 60,000 volumes.—Cologne had its origin in a camp which was pitched upon its site by the Romans in the time of Marcus Agrippa. Afterward the Ubii were transferred to it from the right bank of the Rhine, and it became the Oppidum Ubiorum. Agrippina, the daughter of Germanicus and the mother of Nero, a native of this place, induced her husband Claudius to found a colony here in A. D. 51. The town then received the name Colonia Agrippina, which it still retains in part. The foundations of the Roman walls remain, and may be traced through the heart of the city. Some suppose that traces of the Roman descent of its inhabitants may be found in their features and complexion. Down to the time of the French revolution the leading citizens were styled patricians, and the two burgomasters wore the consular toga and were attended by lictors. From the beginning of the 13th to nearly the end of the 15th century



Cologne was one of the principal cities of the Hanseatic league. When most powerful it could put 30,000 men into the field. In 1259 it obtained the right to require that all goods which arrived in vessels should be unloaded and shipped in Cologne bottoms. Important commercial privileges were granted to it in England. It was the channel of commerce with the East, and had business relations with Spain, Portugal, and Italy. The celebration of the carnival, and the exhibition of puppets, which are still kept up, bear witness to the influence of Italian tastes. Cologne was sometimes called the Rome of the north. Various causes contributed to the diminution of its prosperity. The route of commerce was changed. The clergy acquired undue influence, and feuds arose between them and the citizens. The Jews were expelled. Disturbances were afterward created by the weavers, and the magistrates caused their looms to be destroyed, in consequence of which they left the city. In the 16th century restrictions were placed by the Dutch upon the navigation of the Rhine; and in 1618 the Protestants were banished from the city. As prosperity diminished, the number of beggars and priests increased, until it was said that the beggars were 12,000 in number, and that there were as many steeples in Cologne as there are days in the year. In 1794, when the city fell into the hands of the French, it contained about 40,000 inhabitants, of whom more than one fourth lived by mendicity. The French government at once attacked this social evil. It secularized many churches and religious foundations, and adopted the most stringent measures against the abuses which had grown out of them. In 1814 it was restored to Prussia. The restrictions upon the navigation of the Rhine were removed in 1837; steamboats have been introduced, and railways have been constructed, by which Cologne is connected with all the principal cities of the continent. In February, 1873, a proposition was submitted by Prince Bismarck to appropriate $9,000,000 for the erection and improvement of fortifications. The *Kölnische Zeitung* is one of the most influential newspapers in Germany, being the organ of the liberal party, as the *Kölnische Volksblätter* is of the Roman Catholics.

COLOGNE WATER. See EAU DE COLOGNE.

COLOMBIA, United States of (*Estados Unidos de Colombia*), formerly NEW GRANADA, a republic of South America, lying between lat. 12° 21′ N. and 1° 20′ S., and lon. 68° 52′ and 83° 5′ W. It is bounded N. by the Caribbean sea, N. E. and E. by Venezuela, S. E. by Brazil, S. by Ecuador, and W. by the Pacific ocean and Costa Rica. Its extreme length from N. to S. is about 1,000 m., extreme breadth about 760 m.; but its average breadth is much less, it being only 28 m. wide at the isthmus of Panama. The area is estimated at from 480,000 to 521,000 sq. m. The republic is divided into nine federal states, which, with their areas, population, and capitals, are as follows:

STATES.	Area, sq. m.	Population, 1870.	CAPITALS.	Population.
Antioquia	24,823	365,974	Medellin	14,000
Bolivar	27,027	225,060	Cartagena	8,500
Boyacá	33,849	482,874	Tunja	8,000
Cauca	260,000	435,078	Popayan	8,000
Cundinamarca	79,845	409,602	Bogotá	46,000
Magdalena	26,950	85,255	Santa Marta	2,000
Panama	31,921	220,542	Panama	18,000
Santander	16,293	425,427	Socorro	12,000
Tolima	18,476	230,821	Ibagué	5,000
Total	518,384	2,880,633		

Bogotá, the national capital, with its environs, forms a federal district, but the city is also the capital of the state of Cundinamarca.—The coasts of Colombia are deeply indented by large and fine bays, the principal of which are the gulfs of Darien and Maracaibo on the Caribbean sea and the gulf of Panama on the Pacific. There are many smaller bays on both oceans, which make excellent harbors. Among the chief ports, besides the free ports of Panama and Aspinwall or Colon, are Cartagena, Sabanilla, Santa Marta, and Rio Hacha on the Atlantic, and Buenaventura on the Pacific. Chiriqui lagoon and Porto Bello, on the Caribbean sea, and Humboldt, Cupica, and San Juan or Chirambira, on the Pacific, also furnish good harbors. There are numerous islands along the coast, none of which are very large. In the Caribbean sea are the islands of San Andrés and Providence. In the Chiriqui lagoon are 11 islands, of which Boca del Toro is the largest, and there are many more along the coast of Cartagena. In the gulf of Panama are the island of Tobago and a group called the Archipelago of Pearls.—The surface of Colombia is more equally diversified than that of any other South American state, being nearly evenly divided into mountain, valley, and plain. Not far from the borders of Ecuador, about lat. 1° 20′ N., the range of the Andes separates into two branches. The W. branch, which follows the line of the coast, is called la Cordillera de la Costa. The E. branch pursues a N. E. course from the point of separation until it reaches lat. 1° 50′ N., when it again divides and forms two chains nearly parallel, between which lies the valley of the Magdalena. The most easterly of these chains, which follows the right bank of the Magdalena, is called the E. Cordillera of Cundinamarca. Between the central and the coast range is the valley of the Cauca, and W. of the latter the mineral region of Choco. By some the eastern range is called the Cordillera de la Suma Paz, from the mountains of the name near Bogotá; the central, the Quindiu; and the western, the Choco. The latter, though comparatively low, has few and difficult passes. The E. branch is much the greatest in extent, and consists of a series of table lands or plateaus, from 8,000 to 14,000 ft. in elevation. In this plateau, which is cool and salubrious, the ancient Chibchas had their seat. It produces in the greatest profusion the fruits and grains of the temperate zone, and

part of the isthmus are covered with luxuriant and almost impenetrable forests, and are little known. The whole Atrato valley was once a vast estuary of the sea, whose waves broke upon the very feet of the Cordilleras. The fossiliferous rocks near the head waters of the Tuira show that the country was at one time submerged by the Pacific ocean, shell fish of the same character as the fossils being found living both in the Pacific and the Atlantic at the present time. The swamps about the Atrato river rest on beds of gold-bearing clay, which the natives wash with considerable profit. Toward the close of the last century a channel was cut by a monk across the so-called isthmus of Raspadura, connecting the head waters of the Atrato and of the San Juan, passing near Quibdo, lat. 5° 50′ N., by which communication by boats is still maintained between the Atlantic and the Pacific. The valley of the Cauca, between the W. and central ranges of the Cordilleras, is one of the richest, most fertile, and most populous districts in South America. It consists of two plateaus of different elevation and temperature. The soil is deep, and tinged with a red or yellow color. The pastures are rich, and the lands are well cultivated. The valley of the Magdalena comprises an area of about 75,000 sq. m. The soil is very fertile, but the climate is hot, and in portions insalubrious. Owing to the wide ramifications of the Andes, a large part of Colombia lies at an elevation of from 5,000 to 10,000 ft. above the sea; but in consequence of the unhealthfulness of the coast and the inaccessibility of the mountain passes, the great resources of the country are comparatively undeveloped.—On the east the river Orinoco forms a part of the boundary line between Colombia and Venezuela, and on the south the Putumayo separates it from Ecuador. Into the former flow the Guaviare, Vichada, Meta, and a number of smaller streams. The principal affluents of the Marañon or Amazon in the republic, besides the Putumayo, are the Rio Caqueta, sometimes called the Japura or Hyapura, and the Rio Negro. The Vaupes or Ucayari is a branch of the latter. Colombia has the right of navigating the Amazon and the Orinoco. But the most important of all its rivers is the Magdalena, with its tributary the Cauca. They traverse nearly the entire country from N. to S. They both rise in the Andes, about lat. 2° N., and pursue a nearly parallel course, the former on the east and the latter on the west of the central range, until they unite in lat. 9° 20′ N., again to divide in lat. 9° 57′, and fall into the Caribbean sea by two deltas, one in lat. 10° and the other in lat. 11° 7′, forming an island of 3,150 sq. m. The Magdalena, navigated by steam to Honda, is on an average 1,750 ft. lower than the Cauca, whose stream is therefore very impetuous. The Funza, which rises 100 m. N. of Bogotá, runs in a S. W. direction to Tequendama, where it plunges down a precipice over 600 ft. high, falling from the region of oaks, willows, and wheat, to that of the palm and sugar cane. The Atrato rises in lat. 5° 20′ N., flows N., and falls into the gulf of Darien. To the distance of 180 m. from the sea it is deep enough for the largest ships; and extensive traffic between Quibdo and Cartagena is carried on by *bongos*, or large canoes. The navigation of this river and those of the isthmus was prohibited on pain of death by Philip II., lest foreign powers should gain a knowledge of means of connecting the two oceans. The rivers draining the W. chain of the Cordilleras into the Pacific are small. The most important are the Patia and the San Juan, which communicate with the high, salubrious, and fertile districts of Popayan, Pasto, Tuquerres, and the famous valley of Cauca, which Bolivar called the "Italy of America." Small lakes are numerous in the mountains, but there are none of large extent. Paletara, Las Papas, Una, and Caucagua are the most noteworthy. Into Guatavita, a small lake near Bogotá, the Indians are said to have thrown their treasures when about to abandon the country to the Spaniards. Curious and valuable articles have been fished up from its depths, but attempts made to drain it have proved a failure. —The geological conditions of Colombia are equally extraordinary and perplexing. Everywhere are found traces of stupendous cataclysms, and a disarrangement and intermixture of primitive and sedimentary rocks, which seem to set classification at defiance. In some places great rivers and even small streams have cut through mountains of the hardest rocks, leaving dizzy escarpments on each side; in others are enormous subsidences in the earth, as if the props of its surface had suddenly given way, or vast caverns glistening with stalactites; while everywhere colossal masses, lifted high above the general level, attest the violence of volcanic agencies. These agencies are still active in places, as in Batan near Sogamoso, where the soil is so much heated that, although in the heart of the Andes, it produces all the fruits of the tropics. The celebrated Colombian geologist, Joaquin Acosta, describes great glaciers which he saw in the Paramo of Ruiz, a phenomenon which escaped the attention of both Humboldt and Boussingault. Col. Codazzi demonstrated that in the highlands of Bogotá, Tunja, and Velez, where is now the densest population, there once existed a system of broad and deep lakes, which, breaking through their barriers, precipitated themselves through what is now the river Suarez or Sogamoso into the ocean, leaving the traces of their irruption boldly marked on the face of the country. The same authority conceives that this great cataclysm may have occurred within the past four centuries. Some evidence in support of his theory is afforded by two great stones which have been discovered on opposite sides of what must have been the borders of the principal lake; both

face toward the points of rupture of the mountains, and the faces of both are covered with sculptures, among which are distinguishable figures of the frog (the Chibcha sign of water) with outspread feet, and human figures with upraised arms, in attitude of surprise or alarm. Among the natural curiosities of the country are the falls of Tequendama; the natural bridge of Pandi or Icononzo, spanning the river Suma Paz at an elevation of 600 ft.; the cascade of the Rio Vinagre, so called from the sulphuric acid with which its waters are charged; the great orifices called Hoyo del Aire and Hoyo de los Pájaros, near Velez; the Peñon de Quitisoque, from the symmetrically pierced summit of which fall three beautiful streams of water; the Fura-Tena (man and woman in the Chibcha language), and the Boqueron de Peña Armada, which are two stupendous cuts or excavations made by the Rio Minero, the second 10,650 ft. deep; and the natural tunnel of the Rio Suarez.—From Costa Rica to Venezuela, Colombia abounds in auriferous alluvions of great extent. There is hardly a state which does not possess in its soil more or less gold. It is claimed that Choco, Antioquia, Mariquita, Popayan, Pamplona, Ocaña, Bucaramanga, and other places are exceedingly rich in that metal. The auriferous sands of Antioquia, according to M. Dufrénoy, afford results very nearly coinciding with those of California. Small diamonds are found with the gold, and in the same district the sulphate of mercury is abundant. Choco produces platinum, and Muzo emeralds; and in various parts of the country are mines of silver, copper, lead, iron, quicksilver, coal (in Bogotá, Cali, Soata, Chiriqui, &c.), amethysts, and other varieties of rare and valuable stones and minerals. The great coal bed of Cali, it is believed, extends beyond the Cordilleras to the Pacific. On the table lands of Bogotá, Tuquerres, Tunja, and Pamplona rock salt abounds, and lime, sulphur, alum, magnesia, asphaltum, and other valuable minerals exist in inexhaustible quantities in various parts of the republic.—The climate of Colombia presents remarkable contrasts and nearly every variety of temperature. The lower part of the valley of the Magdalena is oppressed with almost tropical heat. The waters of the river are lukewarm, and at Honda, 1,000 ft. above the level of the sea, stones exposed to the sun's rays are too hot to place the hand upon. The mortality in this region is great, more especially among children. At Cartagena, as well as on the W. coast, the yellow fever is endemic, and the lowlands are dangerous to both Europeans and the people of the highlands. On the plateaus the air is salubrious and the temperature is that of perpetual spring. On the plain of Bogotá, which is 8,000 ft. above the sea, the thermometer ranges from 55° to 70° F., and the rain in the wet season falls but a few hours daily in the afternoon. The summits of the Cordilleras are usually covered with mists, and the tops of the highest with perpetual snow. In the forests of Darien the rain falls almost unceasingly, and the gulf of Choco is seldom free from violent storms.—The flora combines almost all the products of the tropical, intertropical, and temperate zones. Within a single day's journey one may encounter the four seasons of the year and the vegetable peculiarities of all these zones. Rice, cotton, tobacco, sugar cane, and all tropical fruits grow along the coast; and the elevated plains yield maize, wheat, potatoes, and all the European fruits. The vast forests, yet imperfectly explored, abound with valuable productions. In Popayan the cinchona grows to perfection, and the sides of the mountains of Tolima are clothed to an elevation of 8,500 ft. with wax palms 200 ft. high. Besides these are found the pitayo, cedar, balsam of Tolu, vanilla, lignum vitæ, mahogany, caoutchouc, and the three trees perhaps most precious of all, the albataque, the vine of the cross, and the arisa, all remarkable specifics, the first against inflammation, the second for stanching effusions of blood, and the third for instantaneously stopping bleeding at the nose. Notwithstanding the luxuriance of the vegetation, the species are not intermingled. Each kind occupies some tract of its own, where it flourishes to the almost total exclusion of others.—Colombia abounds in animal life. The rivers swarm with alligators and wild fowl, and myriads of flies render life almost unendurable in the lowlands. Boa constrictors and poisonous serpents, the jaguar, the puma, and others of the feline tribe, and monkeys of many species abound in the tropical forests. The sloth, armadillo, anteater, and cavy also inhabit the lower forests; deer of different kinds are found at all heights; and the bear and marmot approach the limits of perpetual snow. At the height of about 3,000 ft. the alligator and boa constrictor disappear, and the tapir, the largest quadruped of the country, is seen. Popular tradition reports the existence in the vast unexplored forests of the *panchique* and *mancarita*, enormous quadrupeds never seen alive, but whose tracks, those of the first round, and those of the second marked with three great toes, have been often observed in the mountains of Coconuco in Popayan, and at Piedecuesta in Santander. It is affirmed that on the line of the tracks of the panchique the branches of the trees have been broken off to the height of 15 feet. The condor soars above the snow line of the Andes, and the forests are alive with innumerable varieties of insects and birds. Among these the changeable butterfly of Muzo is without a rival in its beauty, and the troopial is not excelled by the nightingale for its song. The bird of Velez, called *sol y luna* (sun and moon), has the image of both those luminaries on its wings. On the coast turtles and fish abound, and pearls and coral are found in the bay of Panama and near Cartagena.—The population of Colombia is made up of

whites, mostly of Spanish origin, negroes, and Indians, and their mixtures. The whites constitute rather less than 1,000,000 of the total population, and the mestizos about the same number. Of mulattoes and civilized Indians, there are about 300,000 each, and the remainder is made up of negroes, zambos, and savage Indians numbering 120,000. The better classes of the people are distinguished for intelligence, festive humor, hospitality, and generous impulses. The educated classes rank among the first in South America for their scientific and literary culture. The people of Socorro and Antioquia are laborious and enterprising. The women of Antioquia, Bogotá, Ocaña, and other cities are celebrated by travellers for their grace and beauty. In Bogotá the French fashions predominate, and the inhabitants incline to European manners. Gaming is universal, and cock fighting is a favorite sport. On the coast the people, from the climate, are wanting in energy and color. The llaneros on the plains wear nothing but a shirt and light drawers, a straw hat, and bark sandals. They ride without a saddle, and live almost entirely on beef. The language is generally Spanish, excepting among the uncivilized Indians, who speak their own aboriginal tongues.—Industry is generally backward. Agriculture is mostly in the hands of the converted Indians, who cultivate the soil in the rudest manner, and the reclaimed land bears but a small proportion to the whole. The cereals are raised to some extent on the elevated plains, and rice, cotton, sugar, coffee, tobacco, cacao, and tropical fruits along the coast. On the eastern plains, toward the Orinoco, the inhabitants, who are chiefly creoles, are devoted almost exclusively to the raising of horses, mules, and cattle. For want of both capital and labor, the mining industry is vastly inferior to the mineral resources of the country. The chief silver works are those of Santa Ana, near Bogotá. Gold abounds in the entire Atlantic region, and, in spite of the rude machinery used, the quantity obtained is far from insignificant; the washings on all the tributaries of the Atrato are extremely productive, but less so E. of the Cordilleras. The emerald mines of Muzo, in the valley of Tunja, near Bogotá, are worked carelessly, but produce enough to meet the constant demand from Europe. The pearl fisheries are mostly neglected. Coal, copper, and iron are mined to some extent near Bogotá; and the salt mines at Cipaquirá, about 30 m. N. E. of Bogotá, produce enough to supply the neighboring states. Manufactures can scarcely be said to exist, native industry not sufficing to supply the wants of the country. Almost all manufactured articles in use are imported. In Bogotá and some other towns cotton and woollen cloths, carpets, straw hats, soap, and leather are produced, but not to any great extent.—The commerce of Colombia, though fast increasing, is still far below the capabilities of the country. The exports consist mainly of cotton, cinchona, coffee, cacao, India rubber, raw hides, tobacco, silver ore, cochineal, indigo, other dyestuffs, and emeralds; and the imports, of cotton, linen, woollen, and silk fabrics, clocks and watches, hardware, machinery, firearms, gunpowder, fermented liquors, &c. The total value of the exports and imports for 1870 was as follows:

COUNTRIES.	Exports.	Imports.
England	$1,849,000	$2,891,889
Germany	2,720,000	168,502
France	1,491,000	1,472,422
Venezuela and Peru	333,000	240,261
United States	663,000	407,284
West Indies	228,000	211,326
Other countries	1,000,000	663,138
Total	$8,284,000	$6,053,772

One half the trade is carried on through the isthmus, the exports and imports of which *in transitu* average each about $50,000,000. The direct exports and the imports for 1873 show an increase of 75 per cent. as compared with those of 1870, chiefly due to a larger number of steamship lines to Colon (Aspinwall). About 75 per cent. of the goods exported through that port go to the United States. Most of the Colombian commodities are known in England only as Venezuelan (Maracaibo) productions. Steamers run weekly from Panama to the principal Pacific ports S., and to San Francisco and intermediate ports N.; to Aspinwall there are American steamers bi-monthly, and several British and French lines; and in 1873 an American line was established between New York, Santa Marta, Sabanilla, and Cartagena. The annual shipping movements in all the principal ports comprise about 1,200 vessels, steam and sail, with an aggregate of 300,000 tons. Steamers ply on the Magdalena, but the navigation of this river is growing more and more difficult each year. The internal carrying trade is done by *bongos* (large canoes) on the rivers, and by mules. Many new roads are in process of construction; but much has yet to be done in this respect. Besides the railways from Panama to Aspinwall (48 m.), and from Sabanilla to Barranquilla (18 m.), both in prosperous operation, proposals were made in 1873 to build other lines to the extent of 800 m., to be completed in 12 years, at a nominal cost of $85,000,000. Some surveying and grading have already been performed (January, 1874). With the telegraphs on the two railways now running, and that from Bogotá to La Mesa, it is expected that at the end of 1874 1,500 m. of wires will be established. A submarine cable from Aspinwall to Kingston, Jamaica, has not been in use for over a year.—Bogotá, Medellin, and some of the other state capitals have each a university or collegiate school, besides seminaries, and scientific, normal, and primary schools. Large appropriations were made by congress in 1873 for the establishment of new schools, so that Colombia will soon be in the matter of primary instruction among the most advanced of the

South American states. The government supports a district school in each parish.—The government of Colombia is republican, founded on a written constitution adopted in 1863, modelled after that of the United States, but differing in some particulars. The executive power is vested in a president elected for two years; the legislative authority in a congress, consisting of an upper house, or senate, and a house of representatives. The senate has 27 members, each of the nine states sending three. The house of representatives, elected by universal suffrage, is made up of delegates from the several states, each sending one member for every 50,000 inhabitants, and an additional one for a fraction of 20,000 and over. A vice president, elected for the same term as the president, acts as chairman of the senate. The president's powers are exercised through four ministers, or secretaries, viz., of the interior and of foreign affairs, of finances, of the treasury and the national credit, and of war, all responsible to congress. The highest court of justice is the supreme court, which has three judges and a procurator general. Each of the states has its own legislature and executive officer. The Roman Catholic faith predominates, the head of the hierarchy being the archbishop of Bogotá; but there is absolute independence of church and state. All other religions are tolerated, and there is perfect freedom of worship. The army in time of peace consists of 1,420 men; in time of war, each state furnishes a contingent of 1 per cent. of the population. There is no navy. The national income, about one half of which is derived from the customs, was made up of the following elements in 1870:

Customs receipts	$1,431,923
Salt monopoly	758,329
Panama railway	250,000
Mint	29,213
Postal service	51,282
National property	26,600
Public lands	6,817
Sundry receipts	185,613
Total	$2,739,777

The expenditures of the same year were a little over $3,000,000. The total income for the year ending Aug. 31, 1872, was $3,219,733; for 1873 it reached $3,400,730; and the expenditures for the latter year were $3,250,730, leaving a surplus of $150,000. According to the president's message of April 4, 1872, the foreign debt amounted to $33,362,250, and the home debt to $9,899,710. The interest paid on the former was about $750,000 annually, under the act of congress decreeing that 37½ per cent. of the net customs receipts should be thus applied. The foreign debt has been, however, by agreement with the creditors, transformed into a debt of $10,000,000, at an annual interest of $450,000, dating from Jan. 1, 1873.—The inhabitants of the country on its discovery were, like those of Mexico and Peru, distinguished into two grand branches: the savages of the lowlands and coast regions, and the semi-civilized family of the table lands. The Colombian highlanders were the Muyscas, or more properly Chibchas, the word Muysca in the Chibcha tongue merely signifying "men" or "people." The origin and the elements of civilization introduced among them were attributed to two mythical beings, Bochica, or Bochia, and Nemterequeteba, who are frequently confounded with one another. Bochia was the more mythical of the two, was regarded as divine, and even as equal to the sun. His companion Chia, or Huitaca, occasioned through her magical art the submersion of the beautiful valley of Bogotá, and for that reason was banished from the earth by Bochia, and made to revolve round it as the moon. Bochia next struck the rocks of Tequendama, and thereby opened a passage through which the waters flowed off in the neighborhood of the Giant's Field. Such is the traditional origin of the picturesque falls of Tequendama. Nemterequeteba, surnamed Chinzapogua (the messenger of God), corresponding to the second Buddha of the Hindoos, was regarded as a human being. The country was ruled by three powers. The spiritual chief was the electoral high priest of Iraca or Sogamoso; the temporal princes were the *zaqui* of Hunsa or Tunja, and the *zipa* of Funza, who would seem to have been in the feudal constitution originally subordinate to the zaqui. The Chibchas had a regular system of computing time; for money they used small circular gold plates, all cast of equal size. Their temples of the sun were built with stone columns, some vestiges of which were discovered in Leiva at the beginning of the present century. Their language was rich, sweet, and harmonious. The people were frugal and industrious, but little versed in the art of war, for, although numbering about 2,000,000, Quesada subjugated them with 200 Spaniards. Other architectural relics in various parts of the country were probably the work of a still more highly cultivated race than the Chibchas, and perhaps allied to the Aymaras of Upper Peru. Of the origin of the coast Indians, such as the Mesayas, Goajiros, &c., still mostly in a savage state, and speaking their own languages, little is known, except that they bear no resemblance to any of the other American families.—The coasts of Colombia were discovered by Alonso de Ojeda in 1499, and visited by Rodrigo Bastidas in 1501, and by Columbus in 1502. It was first called Tierra Firme by the Spaniards, and Castilla de Oro, or "Golden Castile." The conquest was effected in 1536–'7, and the country erected into a viceroyalty called New Granada in 1718. The first efforts for emancipation from Spain were made in 1781 and 1795; independence was proclaimed in 1811, and secured by Bolivar in 1819, when a union was formed with Venezuela and Quito, under the name of the republic of Colombia. (For an account of the struggle for independence, see Bolivar.) This union was dissolved in 1829 by the withdrawal

of Venezuela, and in 1830 Ecuador also withdrew. The republic of New Granada was organized Nov. 21, 1831. In 1832 a constitution was promulgated and the republic was divided into provinces, each of which controlled its local affairs. Under this constitution the president's term of office was four years. Gen. Santander was president from 1833 to 1837 inclusive; Dr. Marquez, 1837–'40; Gen. Herran, 1841–'4; Gen. Mosquera, 1845–'8; Gen. Lopez, 1849–'52; Gen. Obando, whose term was concluded by the vice presidents Obaldia and Mallarino, 1853–'6; Dr. Ospina, 1857–'60. In the beginning of 1860 an important revolution broke out. The liberal party, under the leadership of Gen. Mosquera, rose in arms against President Ospina, who was the representative of the federal or conservative party. Bogotá was captured July 18, 1861, and the reins of government were assumed by Mosquera. The federals, who controlled the southern portion of the republic, made Antioquia the seat of their government. The representatives of the liberal states met in a congress at Bogotá which closed Oct. 20, 1861, assumed the name of the United States of Colombia, adopted a new constitution, and conferred dictatorial power on Mosquera. In November, 1862, Gen. Arboleda, the leader of the conservative troops, was assassinated, and was succeeded by Gen. Canal. An agreement was finally made between the latter and Mosquera, Dec. 29, 1862, which put an end to the civil war. Gen. Canal and his troops submitted to the authority of the United States of Colombia, and the latter granted an anmesty to political offenders. Deputies from all the states met in convention at Rio Negro, in Antioquia, Feb. 4, 1863. Mosquera resigned to this body his dictatorial powers, and the convention appointed a provisional government, composed of five ministers, who were to hold office during the forming of the new constitution. The constitution which was framed bears the date of May 8, 1863. Mosquera was appointed provisional president, to hold office till April 1, 1864, when the executive elected by the people in 1863 was to take his place. During Mosquera's administration there was to be no fixed capital, he having the power to move it where he pleased; after the close of his term it was to be at Bogotá. The president's term of office was fixed at two years. Among the provisions of the constitution was one granting religious liberty, and another confiscating church property. These acts called forth an encyclical letter from the pope to the bishops of the republic, urging them to use every effort to secure their repeal, which, however, was not effected. Dr. Manuel Murillo Toro was elected president for the term 1864–'6. He was succeeded by Mosquera, who was chosen for the two years ending in 1868. He resigned Dec. 6, 1866, giving as reasons that it was impossible to replenish the treasury, which had been robbed of upward of $1,000,000 by false certificates; that the archbishop of Bogotá and other bishops were in rebellion against the executive; and that there was a general desire to disturb the public peace and to make way with him by assassination. His resignation was not accepted. In 1867, in consequence of attacks made on his policy by the majority in congress, Mosquera ordered that body to adjourn, and arbitrarily arrested 68 senators and representatives. Congress passed a resolution of impeachment April 29, and on the same day the president published a decree dissolving that body and declaring the country in a state of war. Most of the states declared in favor of congress, and Mosquera was arrested, May 25. His adherents were soon put down and peace restored throughout the country. Mosquera was tried and sentenced to two years' imprisonment and to lose all civil and political rights; but the sentence was commuted to two years' exile, and he went to Peru. The remainder of his term was filled by Gen. Santos Gutierrez. In 1868 Don Santos Acosta was sent to the United States to conclude arrangements with the government at Washington in regard to the proposed canal across the isthmus. The Hon. Caleb Cushing was sent to Bogotá for a similar purpose. Santos Gutierrez was elected president for 1868–'70. Under his administration the state of Panama suffered much from internal dissensions. An act of general amnesty permitting the return of Mosquera, passed by the lower house of congress, was rejected by the senate. In January, 1869, a treaty was concluded between the plenipotentiaries of the United States and of Colombia granting to the former power the right to construct a canal across the isthmus. It was approved by the president, but through foreign influence rejected by the Colombian senate. In the same year the United States government sent out an expedition under Commander Selfridge to make surveys in the valley of the Atrato. (See CANAL.) In 1870 a new treaty for an interoceanic canal was concluded between Gen. Hurlbut, the United States minister, and the Colombian commissioners, Señor Justo Arosemena and Dr. Jacob Sanchez; and it was approved by the Colombian congress, with some modifications. Gen. E. Salgar, the liberal candidate, was elected president for 1870–'72. He took great interest in popular education, and secured the passage by congress of a bill making an appropriation for normal schools. The bank of Bogotá, with a capital of $235,000, was established Nov. 25, 1870. Manuel Murillo Toro succeeded to the presidency for the term 1872–'4. Among the important measures of his administration is the proposal to build an interoceanic railway from the bay of Buenaventura on the Pacific, across the valley of the Cauca, and thence down the Magdalena to the Atlantic. The portion from Buenaventura to the river Cauca has been put under contract. A contract has also been made for

a submarine cable from Aspinwall to Cartagena and Santa Marta. The act amending the constitution for the establishment of a federal district, comprising Bogotá and its environs, was ratified by the senate Feb. 6, 1872. In December of the same year troubles broke out again in the state of Cauca between the conservatives and liberals, the latter led by Gen. Mosquera, who returned from exile in 1870. In 1873 Santiago Perez was elected president of the republic for the term 1874–'6. The interoceanic canal question had not been settled in 1873, but explorations were still making in the valley of the Atrato for a feasible route.

COLOMBO, or **Columbo,** a city of Ceylon, the seat of government and principal seaport, on the W. coast; pop. in 1871, 100,238. It consists of an open and a fortified town. The latter stands on a rocky peninsula, jutting out into the sea, and having on the land side a lake, a moat, and drawbridges. The interior

Cathedral of Colombo.

presents more of the appearance of a European town than any other place in India except Goa. The houses are built after a plain Dutch fashion, and many of the streets are shaded by trees. It is the residence of the civil and military authorities and most of the European families of Ceylon. The climate is humid but salubrious. The temperature in winter is about 79·1°; in summer, 80·9°. East of this portion of Colombo lies the open town, which is inhabited by a mixed population of Dutch and Portuguese descent. The suburbs are peopled by native Cingalese. The principal edifices are the government house, court house, English, Dutch, and Portuguese churches, chapels, barracks, a military hospital, and a lighthouse. There are various museums, schools, hotels, and libraries. The harbor, which is small, is defended by several forts. The roadstead is safe only during the S. E. monsoon. Colombo is the entrepot for most of the foreign trade of Ceylon, and has a number of commercial houses. It is the seat of an Anglican bishop, and of a Roman Catholic vicar apostolic. The town was occupied by the Portuguese in 1517, taken by the Dutch in 1603, and by the English in 1796. The Natande canal, from Colombo to Putlam, was opened Sept. 23, 1856, and the opening of the first railway in Ceylon was celebrated with great pomp at Colombo in 1858. In 1872 the streets were lighted with gas.

COLON. See Aspinwall.

COLON, the portion of the large intestine extending from the cæcum to the rectum, from the right to the left iliac region. It is divided into four portions: the ascending colon, on the right side, from the cæcum to the edge of the ribs; the transverse, or arch of the colon, from one hypochondrium to the other, below the stomach and above the small intestine; the descending colon on the left side; and the sigmoid flexure, in the shape of the letter S, in the left iliac region, terminating in the rectum or last portion of the intestine. Along its course it presents prominences of its walls, interrupted by three fleshy longitudinal bands, and many fatty appendages formed in the folds of the peritoneum. The peritoneal or serous coat, after covering the intestine, fixes it loosely to the vertebral column by the folds called mesocolon; the muscular coat consists of both circular and longitudinal bands, as in the cæcum; the mucous coat presents a great number of mucous follicles. The arteries of the large intestine are derived from the superior and inferior mesenteric, proceeding directly from the aorta; the veins open into the portal vein of the liver; the nerves are furnished by branches of the solar plexus. The colon in man will average about 4½ feet in length, and about 2 inches in diameter, being about a quarter as long and twice as wide as the small intestine; though the capacity is nearly the same, the absorbing surface is scarcely half that of the smaller tube, and this difference is increased by the absence of folds in the large intestine. The ascending colon lies upon the right kidney and quadratus lumborum muscle; above it is the duodenum, and in front the folds of the small intestine; the descending portion is on the left kidney and corresponding muscle, and is also covered by the small intestine. The sigmoid flexure is generally in contact with the abdominal walls, though, from its freedom of movement, it may assume a variety of curvature and position. The whole colon is very liable to displacement by the pressure of its own accumulated contents, by tumors from within, and by corsets and other articles of dress from without. It retains its sacculated shape throughout, but very gradually decreases in size toward the rectum; the fatty appendages (*appendices epiploicæ*) appear to be small reservoirs of fatty matter, and are sometimes greatly increased in cases of remarkable obesity. After the food has passed the cæcum, little is left but excrementitious matter, which collects in the sacs

of the colon, the forms of which it assumes and preserves even after having passed through the rectum. When, from want of tone in the bowel, or other causes, the fæces are delayed in these sacs, they often acquire extreme hardness and roundness, causing painful and even dangerous symptoms. Like the rest of the intestine, the colon is subject to inflammation, ulceration, and other diseases of mucous membranes; it is also the seat of dysentery.—The colon is separated from the small intestine in fishes by a slight constriction; this is the case with most reptiles. In birds the short and straight large intestine is continued from the small without a distinct separating valve, and ends in a cloaca common to the digestive, urinary, and generative organs. In mammalia there is generally a well marked colon, though in some of the edentata there is no distinction between large and small intestine; in carnivora it is short, wide, and cylindrical; in the herbivora, long and sacculated; in the horse, whose intestines are ten times as long as the body, the colon has a length of 19 feet, much curved and sacculated, and the lower portion attached loosely by a very long mesocolon; in rodents it is not much larger in diameter than the small intestine, but is provided with deep sacs; in the monotremata it gradually increases in size to the rectum; in the monkeys it is very similar to that of man.

COLONIZATION SOCIETY. The idea of sending a colony of persons of African descent from the United States to Africa appears to have first occurred to the Rev. Samuel Hopkins and the Rev. Ezra Styles of Newport, R. I. They issued a circular on Aug. 31, 1773, in which they invited contributions toward the founding of such a colony. A contribution was made Feb. 7, 1774, by a society of ladies of Newport, and aid was received from Massachusetts and Connecticut. The revolutionary war interrupted these labors. In 1784 and 1787 Dr. Hopkins renewed his efforts to obtain funds for colonization, and endeavored to make an arrangement by which free blacks from America might join the English colony of Sierre Leone. Not being successful in this, he published in 1793 an appeal in which he urged that the plan of colonization ought to be adopted in the several states and by the federal government. He continued to agitate the subject from time to time until his death, Dec. 20, 1803. The first emigrants sent from the United States were a company of 38 colored persons who were taken from New Bedford to Sierra Leone in 1815. The subject of colonization in Africa was brought before the legislature of Virginia in 1800–'2, but no definite results were obtained. Samuel J. Mills, Robert Finley, Elias B. Caldwell, and Francis S. Key were conspicuous for their exertions in drawing attention to the plan; and a meeting was held at Princeton, N. J., in the autumn of 1811, to consider the steps to be taken for the organization of a colonization society. A second meeting was held Dec. 23, and the constitution of the "American Colonization Society" was adopted Dec. 28. The first officers were elected Jan. 1, 1817, and the same year Samuel J. Mills and Ebenezer Burgess were sent to Africa to select a site for the colony. They chose Sherbro island and the coast adjoining. Mills died on the return voyage. In March, 1819, congress appropriated $100,000 for the purpose of carrying back to Africa such slaves as should be surreptitiously imported. Under the construction which was put upon this law by President Monroe, part of its design was that a residence should be provided in Africa for the agents of the United States and such slaves as were sent back. For this purpose it was necessary that emigrants should be sent out and a settlement made. The formation of such a settlement being the object for which the colonization society was organized, the government and the society determined to coöperate. The society designated 88 persons as emigrants, and the government chartered a ship, appointed an agent, and placed $30,000 at his disposal. The ship sailed Feb. 6, 1820. The emigrants were to erect huts for the reception of at least 300 recaptured Africans, and cultivate land for their own support. They did not succeed in establishing themselves on Sherbro island, but in April, 1822, made their settlement at Cape Mesurado, between Sierra Leone and the Ivory coast. The society was represented in the colony by Jehudi Ashmun, who arrived there Aug. 9, 1822. Under his leadership the colonists repulsed on Nov. 11 an attack made by 800 natives, and a second assault on Dec. 2, made by about twice the number. The agents of the United States were instructed not to attempt to exercise any power or authority over the colonists, and the government of the colony was assumed by the society. The board of managers adopted, on Jan. 26, 1820, a constitution for the colony, by which the powers of government, legislative, executive, and judicial, were vested in the society's agents. Ashmun undertook to exercise the powers which were conferred upon him, but the colonists were not disposed to acquiesce, and Ashmun for a time abandoned his undertaking. The United States government and the colonization society deputed Ralph R. Gurley to investigate the condition of affairs. He had a conference with Ashmun, the result of which was that in 1824 a plan for the civil government of Liberia was adopted, by which the society retained the ultimate decision on all questions of government. A more formal constitution was adopted Oct. 22, 1828, by which a considerable part of the civil power was secured to the colonists. This constitution was changed from time to time, and the share of the people in the government was made greater and greater. After the death of Governor Buchanan in 1841, Joseph J. Roberts, who had previously held the office of lieutenant governor, through election by the people, was appointed governor by the society.

A legislature was in existence, but its laws were subject to the veto of the society, as were also all treaties made by the colony. Several valuable tracts of land had been acquired by treaties made with native chiefs, and duties had been imposed on goods imported. British subjects who traded on the coast included within the territory of the colony landed goods without paying duties; and when their goods were seized by the government of Liberia, they applied to the British government for redress. The British authorities applied to the government of the United States, and were informed that Liberia was an independent political community, and not a colony of the United States; whereupon the British took the ground that Liberia had no existence as a nation, inasmuch as its powers were derived from an association of private individuals, which did not possess and could not impart any political authority; and that the levying of imposts being a prerogative of sovereign power, the rights of British subjects to free commercial intercourse would be enforced by arms. In this emergency the directors of the society, in January, 1846, surrendered such governmental power as they still retained, and recommended the colony to publish to the world a declaration of its true character as a sovereign and independent state. The colonists appointed delegates, who on July 26, 1847, adopted a declaration of independence and a new constitution. In 1848 the independence of the republic was acknowledged by Great Britain and France, and afterward by most of the powers of Europe and America. The Maryland colony, which had maintained a separate existence, united in 1857 with Liberia. The credit therefore is due to the colonization society of having been mainly instrumental in the foundation of Liberia, and of having guided its destinies until it became a self-supporting state. Since relinquishing all direct control over the government of Liberia, the colonization society has continued to send out emigrants, and to furnish them with provisions and temporary dwellings, and has aided in developing commerce and agriculture. It has also labored for the dissemination of Christianity, and for the promotion of education and the general welfare of the country. The abolition of slavery has not by any means put an end to the usefulness of the society; on the contrary, since that event the number of applications for passage to Liberia has very much increased. The receipts of the society from its foundation to Jan. 1, 1872, were $2,364,648 47, and those of the auxiliary societies more than $400,000. The whole number of emigrants which had been sent out at that date by the parent society was 13,598; and 1,227 had been sent out by the Maryland society, and 5,722 recaptured Africans by the United States government. The presidents of the society have been Bushrod Washington, Charles Carroll, James Madison, Henry Clay, and J. H. B. Latrobe. (See Liberia.)

COLONNA, a princely family of Italy, of which the founder claimed that he brought from Jerusalem a part of the column (*colonna*) to which Christ was bound when scourged. It is now divided into the three lines of Colonna-Paliano, Colonna-Stigliano, and Colonna di Sciarra. Pope Martin V. (Ottone Colonna), several personages who took a conspicuous part in the contest between the Guelphs and the Ghibellines, and many other persons of historical or literary distinction, were members of this family. **I. Fabrizio,** lord high constable of Naples, died there in 1520. He served in the armies of France, and afterward in those of the king of Aragon. In 1512 he was taken prisoner at the battle of Ravenna by the duke of Ferrara, by whom he was treated with much consideration. **II. Prospero,** a general, cousin of the preceding, died in 1523. When Charles VIII. of France invaded Italy, Prospero embraced his cause, chiefly because the Ursini, the hereditary enemies of his house, took the opposite side. He afterward changed sides, and fought against France. At the battle of Villafranca, in 1515, he was taken prisoner; but having been restored to liberty, he again took the field against the French, gained the battle of Bicocca in 1522, and distinguished himself by the vigor of his operations, which were cut short by his death. **III. Vittoria,** a poetess, daughter of Fabrizio Colonna, born in the castle of Marino in 1490, died in Rome in February, 1547. She was affianced by her parents when four years of age to Ferdinando Francesco d'Avalos, son of the marquis of Pescara, a child of the same age; and in their 17th year they were married. Shortly afterward her husband engaged in the war between France and Venice, receiving from Vittoria at parting a superb pavilion and an embroidered standard, as well as some leaves of palm in token of her hope that he would return crowned with honor. In his absence she occupied herself with literature and with her correspondence with him. In order to see him occasionally, she removed from Ischia to Naples. In the battle of Pavia (1525), at which Francis I. fell into the hands of his enemies, Vittoria's husband received wounds which brought on a fever, and he found it necessary to warn his wife of his dangerous condition. She at once set out for Milan, and at Viterbo was met by the intelligence that her husband was dead. Her grief caused her to lose her reason for a time. When restored she resisted offers of a second marriage from several princes who sought her hand. She turned again to literary studies, and consoled herself with the composition of poems in memory of her husband. She also composed canzonets and sonnets of a devotional character, to which she gave the title of *Rime spirituali.* In 1541 she entered the convent di Suore in Orvieto, and afterward that of St. Catharine in Viterbo. Her beauty and virtues have been celebrated by Michel Angelo, Ariosto, and other poets. Her bust

was placed in one of the collections of the capitol in 1845. A selection of her poems is contained in Gironi's *Raccolta di lirici italiani* (Milan, 1808). A memoir of her is appended to the Life of Michel Angelo by John S. Harford (London, 1857). **IV. Marc Antonio,** duke of Paliano, distinguished for the part which he took in the battle of Lepanto (1571), died Aug. 2, 1584. On his return to Rome after that battle, he was received with the highest marks of honor, and was afterward made viceroy of Sicily by Philip II. of Spain. **V. Fabio,** born in Naples in 1567, died there in 1650. He was the author of many books on botany, and the first to write a botanical work with copperplate illustrations (*Φυτοβάσανος*, Naples, 1592).

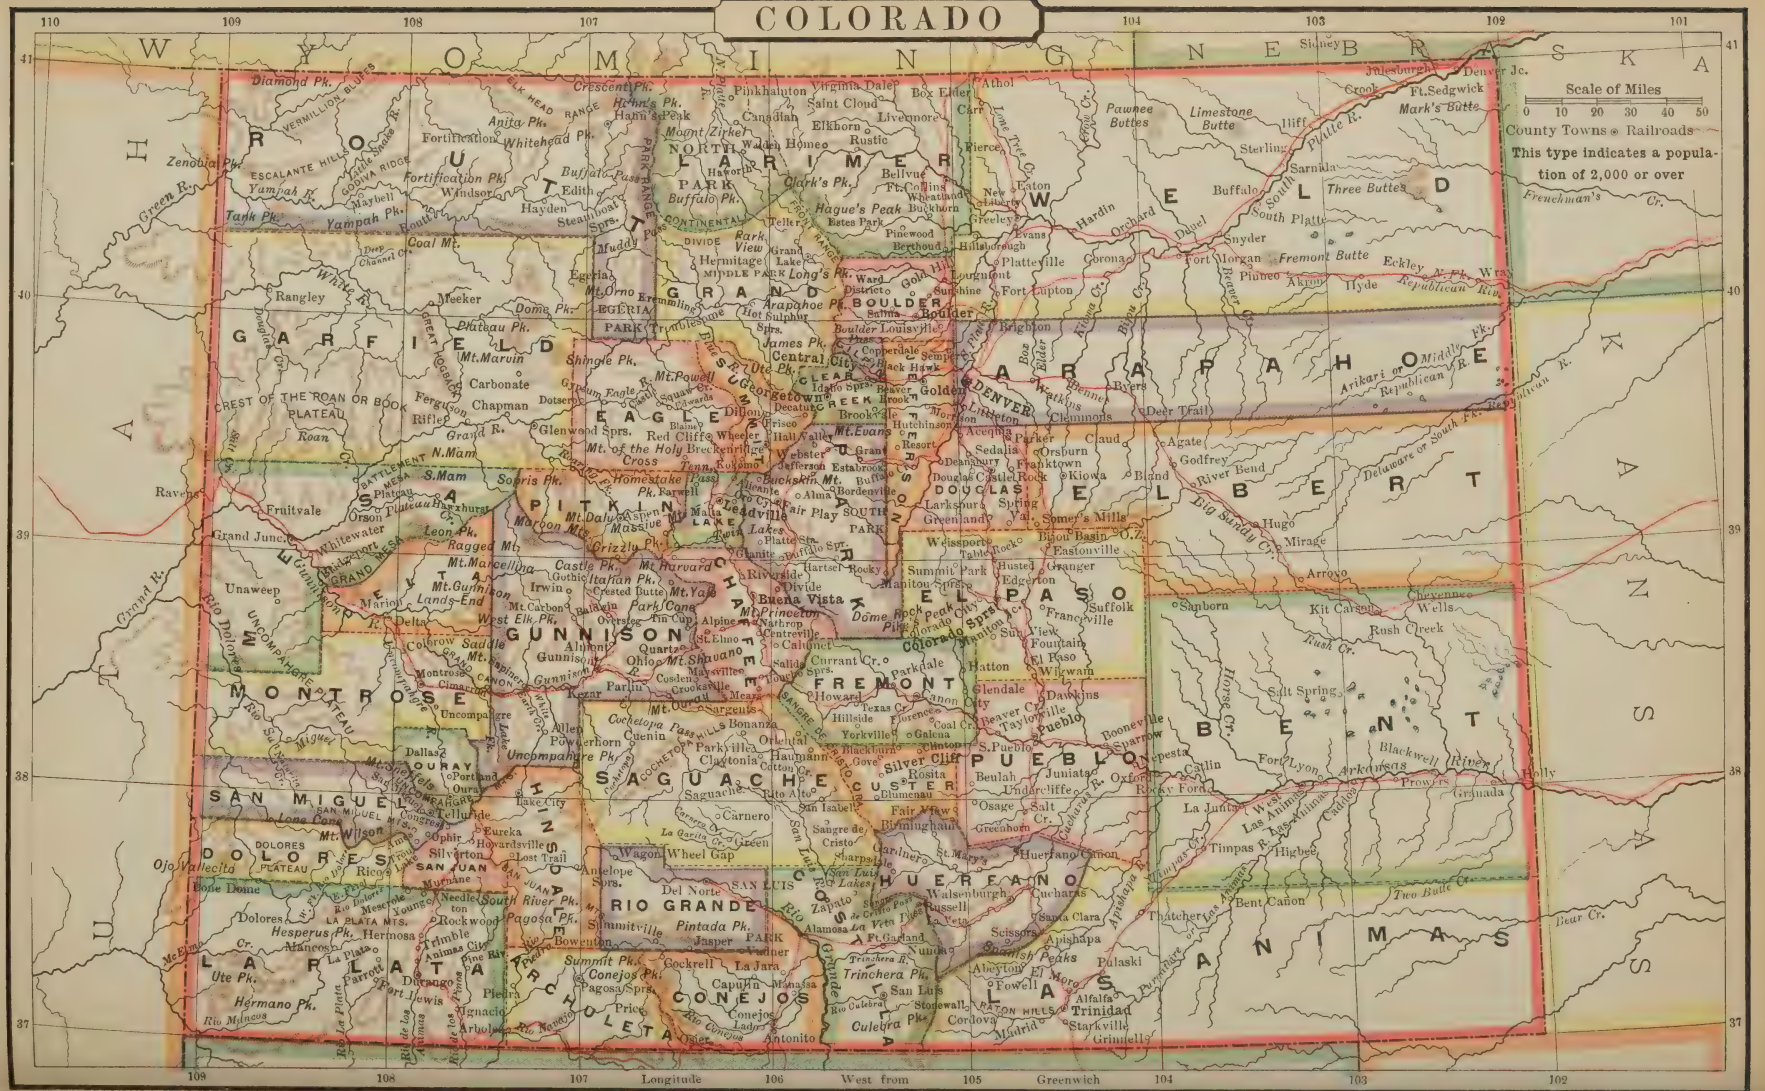
COLONSAY, one of the Hebrides or Western islands of Scotland, S. W. of Argyleshire, between the isles of Islay and Mull, and connected at the S. end with that of Oronsay, from which it is separated at high water only; pop. about 800. Including Oronsay, the length is 12 m., the breadth from 1 to 3 m. A great portion of the soil is well cultivated, producing potatoes and barley; and cattle and sheep of a superior breed abound. The cod fisheries are extensive, and there are two capacious roadsteads and a good quay at Portnafeamin, the harbor of the island. The ruins of a stronghold of the early lords of the isles are situated in the middle of a lake on this island. Colonsay and Oronsay were among the early monastic stations, and next to Iona they contain the most famous remains of religious edifices in the Hebrides.—Little Colonsay, an islet between Staffa and Gometra, affords good pasturage for sheep, but contains few inhabitants.

COLONY (Lat. *colonia*, from *colere*, to cultivate), a word originally applied to a body of people established in a foreign country, whether remaining subject to the government of the mother country, or having an independent government of their own. It is now used as a designation of the territory inhabited by such persons. The Phœnicians first set the example of colonization. Their colonies, established upon the islands of the Mediterranean, and the coasts of Africa and Spain, were founded for the purpose of promoting commerce, but contributed powerfully to the progress of civilization. Carthage, itself a colony of the Tyrians, in turn sent forth colonies in the prosecution of its commerce, which were remarkable for their number rather than for their importance. Her colonies, unlike those of Tyre, remained in political dependence upon the mother country. The Greeks founded colonies upon the coasts of Macedonia, Thrace, and Asia Minor, upon the islands of the Archipelago and the Ionian sea, in Crete, Rhodes, Cyprus, southern Italy, Sicily, and Cyrene, and on even remoter shores of the Mediterranean. The colonies were generally distinguished as Dorian, Ionian, or Æolian, according to the Grecian tribe from which they originated, and soon surpassed even their mother countries in poetry, philosophy, and art. Their prosperity was promoted by political independence. Miletus possessed four ports and more than 100 vessels, and in its turn became a colonizing power. Ephesus, Syracuse, Rhodes, and Cyrene were all rich and powerful cities. In many cases the political institutions of the colonies resembled those of the mother country, but there were some whose institutions were a great improvement upon those which prevailed in Attica and Peloponnesus.—As fast as the Romans extended their conquests they established colonies in the countries conquered, for the purpose of consolidating their power. The Roman colonies were parts of the Roman state, their members retaining all the rights of Roman citizens, including that of *suffragium* or voting, and that of the *honores* or of holding office. Land was assigned to them from the conquered territory. The original inhabitants among whom these colonists were sent, though subjects of Rome, were not Roman citizens in the full meaning of the word. The privileges allowed them varied according to circumstances. After the decline and fall of the Roman power, there were no new colonies established up to the time when Genoa and Venice became powerful states. The Genoese colonies were on the shores of the Hellespont, of the Black sea, and of the sea of Azov. Those of the Venetians were in Candia and Cyprus.—When the discovery of the Cape of Good Hope changed the direction of commerce with the East, the Portuguese established colonies along its route, upon the coasts of Africa and the shores of the Persian gulf. Among their colonies in India were those at Goa, Diu, and Damaun on the Malabar coast, Negapatam on the Coromandel coast, and Malacca. They had also colonies in Java, Sumatra, Celebes, Borneo, and the Spice islands. Upon the annexation of Portugal to Spain, many of the Portuguese colonies passed into the hands of the Spaniards, from whom they were taken by the Dutch. Brazil, the greatest of the Portuguese colonies, declared itself independent in 1822. The more important colonies belonging to Portugal at the present day are the Azores, the islands of Madeira and Porto Santo, the archipelago of Cape Verd, some settlements in Senegambia, Angola (including Benguela, &c.), Congo, Prince's island, Mozambique, Goa, Diu, Macao, Dili, and Kambing.—Spain began to send out colonies after the discovery of the new world. Her first colony was that of Hispaniola (Hayti), which was founded by Columbus in 1492. Those of Cuba, Porto Rico, and Jamaica were next founded. When Mexico was conquered by Cortes (1519–'21), and Peru, Quito, and Chili by Pizarro and his associates, colonies were established in those countries. One of the points kept in view by the Spaniards in the establishments of their colonies was the propagation of the Catholic religion; but the principal object was to secure for Spain the possession of their gold and silver mines, and

the government therefore reserved to itself the exclusive control of commerce with them. Squadrons set sail twice a year from a designated port (at first Seville, afterward Cadiz) for Porto Bello and Vera Cruz, which upon their return voyage brought back treasure to the same port. The interests of the natives were sacrificed to those of the colonists, and those of the latter to the home government. At the same time the interests of the people of Spain were favored by securing them the exclusive right of supplying the colonies with certain European productions, such as wine, hemp, flax, ships, powder, and salt. The practical operation of this system was in the long run unfavorable to Spanish commerce. Its activity was increased upon the removal in 1778 of the restrictions upon it. The colonies on the American continent declared themselves independent early in this century. The more important of those belonging to Spain at the present day are the Philippines, the Mariana and Caroline islands, Ceuta, Peñon de Velez, Melilla, Alhucemas, the Canaries, Cuba, Porto Rico, Mona, Tortugas, and Los Roques. In some of these colonies slavery is still maintained, though the principal Spanish statesmen favor its early extinction.—In combating for its independence the Dutch republic undertook to place its navy in a condition that might enable it to cope with that of Spain. Not satisfied with fighting the Spaniards upon land, the Dutch pursued them on the seas; and after the colonial possessions of the Portuguese passed under Spanish dominion, they attacked the Portuguese and Spanish settlements indiscriminately. The expedition which sailed in 1595, under the command of Cornelis Houtman and De Molinaer, was the first which was sent to the Indies by the Dutch. Early in the 17th century they had deprived the Portuguese of all their settlements in India, with the exception of Goa. In the middle of that century their power was at its height. They obtained exclusive possession of the commerce with Japan, and established a colony at the Cape of Good Hope. The capital of their empire in the East was Batavia, on the island of Java. They had establishments in St. Eustache, in Guiana, and for a time in Brazil. The discovery of New Holland, Carpenter's Land, Van Diemen's Land, and New Zealand was due to them. Their only attempt at colonization in North America was made in the territory discovered by Henry Hudson in 1609, which they called New Netherlands, but which was taken from them by the English in 1664 and named New York. The object of the Dutch in the establishment of their colonies was the promotion of commerce, and their government was confided to trading companies. No attempt was made to change the religion of the people among whom they were founded. Their importance declined with that of the Dutch commerce. Among the more important of those of which Holland still retains possession are the islands of Bonair, Curaçoa, St. Eustache, Saba, half of St. Martin and part of Guiana, Java, Sumatra, Bencoolen, Madura, Celebes, Borneo, the archipelago of Sumbawa, Timor, the Moluccas, and Papua. Slavery was abolished in the Dutch colonies in 1861.—Denmark, under the reign of Christian IV., in 1618 established a colony at Tranquebar on the Coromandel coast, and afterward others upon the coast of Malabar and in Bengal. Trading companies were organized for the management of these enterprises, but they interfered with each other and were abandoned. A new company was organized in 1732, which was more successful. The Danish possessions in India were sold to the English East India company in 1845, and in 1849 the Danish colony in Guinea was sold to Great Britain. Denmark retains the colonies of St. Thomas, St. John, and St. Croix in the West Indies; and Danish merchants have a trading station, with the encouragement of the government, in Greenland. The island of St. Bartholomew belongs to Sweden.—Austria founded the Ostend company in 1722, for the purpose of opening commerce with the East Indies, but has never accomplished anything of importance in the way of colonization.—The policy of colonization was introduced and maintained in France by Richelieu and Colbert. Possession was obtained of Canada, Acadia, of part of Newfoundland, Hayti, Martinique, Guadeloupe, St. Lucia, Grenada, and Cayenne. A factory was established by the French East India company at Pondicherry, and colonies were founded upon the isles of France and Bourbon. At the beginning of the 18th century the French colonies in the different quarters of the world were in a flourishing condition. The French settlements in the East, while Dupleix was governor at Pondicherry, had at their command large fleets and were strong and successful; but under the reign of Louis XV. the French colonies did not receive adequate protection from the home government, and they fell one after another into the power of other countries. France was deprived of her settlements in Newfoundland by the British in 1713, and surrendered Canada, Cape Breton, and some of the West India islands at the close of the seven years' war in 1763. She lost Hayti by revolt during the revolution. Louisiana was ceded to Spain, afterward resumed by France, and then sold (1803) to the United States. But in more recent times French colonies have begun again to acquire importance. The colony which was founded in Algeria in 1830 is the most important one which ever belonged to her. Under Napoleon III. particular attention was paid to the French colonies in the East. Establishments were made upon the islands of New Caledonia and of Pines, at Saigon in Cochin China, in Senegambia, and elsewhere. Among the most important colonies of France at the present day are Algeria, Cochin China, Réunion, Martinique, Guadeloupe, Senegal, Pondicherry, St. Pierre and

Miquelon, Cayenne, Tahiti, New Caledonia, and the settlement on the Gaboon.—England began to establish colonies under Queen Elizabeth. They were sent chiefly toward the East, where they came in conflict with the establishments which had been previously founded by the Portuguese and the Dutch. In 1623 the English were driven from the islands which they had occupied, and confined to their settlements at Madras and on the Coromandel and Malabar coasts. The English colonies in India were under the administration of the East India company, which received its charter from Queen Elizabeth Dec. 31, 1600. Its charter was renewed, and a new company was chartered with similar powers. These companies were afterward united, and their union was ratified by act of parliament in 1708. The East India company was secured in the enjoyment of all benefits directly obtained from the English colonization of India. (See East India Companies.) The British colonization of North America was conducted upon different principles. Though the settlement made at Jamestown in 1607 was a matter of private enterprise, it was taken under the protection of the British government in 1624. Neither that colony nor the one planted by the Puritans in New England in 1620 was ever subjected to the exclusive control of a privileged trading company. The great success attained by the colonies in America which threw off their allegiance to Great Britain, tended to show that the prosperity and development of a colony is promoted by the absence of control and regulation on the part of the mother country. This principle has been introduced into the British colonial system, and although the particular forms of administration vary in the different colonies, they are in general encouraged as far as possible to provide for their own government. Compulsory transportation to remote colonies was long a means adopted by the British government for the punishment of criminals. James I. in 1619 authorized the sending of 100 dissolute persons to Virginia; and the practice was continued afterward. It was found that the criminals were gradually absorbed into society, and the working of the system was upon the whole satisfactory. But a similar success never attended the transportation for crime to Australia, which took the place of that to America; and the system was finally abandoned in 1857. The British colonies and foreign possessions at the present day are India, Ceylon, the Straits Settlements, Hong Kong, Mauritius, Aden, St. Helena, Ascension, Cape Colony, Natal, the Gold Coast, Sierra Leone, Gambia, Australia, Tasmania, New Zealand, Labuan, Sarawak, Malta, Gibraltar, Heligoland, the Dominion of Canada, Newfoundland, Labrador, British Honduras, British Guiana, the Bermudas, the Bahamas, the Leeward islands, Jamaica, St. Lucia, St. Vincent, Barbadoes, Grenada, Tobago, Trinidad, Falkland islands, and several small islands in the Pacific and Indian oceans.—The course of proceeding which is followed by the United States in reference to the settlement of unoccupied territory is a system of colonization. The land is granted to actual settlers gratuitously, or on favorable terms, and the territory is governed by the United States until its population reaches a number sufficient to form a state, when the territory is admitted into the Union on an equal footing with the other states.

COLOPHON, one of the twelve Ionian cities on the coast of Asia Minor, situated about 9 m. N. W. of Ephesus on the banks of the Halesus, a small stream, famed for the coldness of its waters. It was 2 m. from the coast, on which, however, it had a port, named Notium. The city and the port were connected by long walls. It suffered much from the Lydian king Gyges, from the Persians during the Peloponnesian war, and afterward from Lysimachus, king of Thrace. The name Colophon was finally transferred to Notium. Only a few miserable cabins now mark its site. Colophon, according to Strabo, was celebrated both for its navy and its cavalry; indeed, the latter was so efficient, that it was said to carry victory wherever it went. Livy tells us that it was one of the cities honored by the Romans with exemption from taxation. It was one of the seven cities which claimed the honor of having given birth to Homer. Mimnermus and Hermesianax the elegiac poets, Polymnestus the musician, Antimachus, Xenophanes, and Nicander were born there.



COLOR, one of those simple and obvious qualities of physical objects, as perceived by us, which can only be defined by its synonymes, hue, dye, &c., or by some theory respecting the nature of light, of bodies, or of vision, but the mode of manifestation or production of which is far from being equally obvious. The color of healthy arterial blood in the higher animals is always florid red; that of pure sky or air, blue; that of most growing leaves, some shade of green. Many chemical compounds are known by certain colors, but by heat or other agencies these colors are often changed. The colors of certain paints and dyes are to a certain degree permanent, but by exposure to light and air they undergo a gradual change. Probably no colors are absolutely permanent, but those thus named are each so during a certain condition of the substance to which it belongs. Other colors, as those shown by a diamond cut in certain forms, or by a prism, those of mother-of-pearl, of the plumage of birds, and of soap bubbles, depend on some accident of form or size of bodies, or of the structure of their surfaces, and these change with the position of the observer; hence these are known as variable colors. When white or solar light is transmitted through triangular prisms of glass, or other media differing in dispersive power from the air, the beam or ray of white is analyzed, being separated into the seven primary colors, red,

orange, yellow, green, blue, indigo, and violet. The proof that these are the elements of white light was first furnished by the experiments of Sir Isaac Newton, in 1672. It must be added, however, that between any two of the simple colors of the spectrum there is a gradual interchange of hue, so that in fact the different colored rays existing in and obtainable from the white ray are not seven, but indefinite in number. The same sensible hue of certain colors which, when found in the spectrum, cannot be further decomposed, can always be separated by the prism when found in natural objects, giving two or more, but not all of the spectral colors; that is, the colors of natural objects are always compound. Light from white paper gives a complete spectrum; from yellow, a fragment of a spectrum, showing the yellow space bright, with some green and orange, sometimes a faint tinge additionally of blue and red; blue paper gives a whole spectrum, less the orange and red; and so of others. The light of the purest yellow flower, analyzed, shows also some green and orange. On account of the impossibility of obtaining pure pigments, a colored solution or glass transmits not only the rays that make up its own color, but other colors that in the spectrum are neighboring to these. Light coming through a blue glass is found to contain a strong blue element, feebler green and indigo, and still feebler yellow and violet. Looking through the blue glass at a spectrum, the same colors are seen, and in corresponding degrees of vividness. The blue medium passes through itself also the closely related rays, but it extinguishes or cuts off the more distant. Bodies vary in color with their mechanical division. Light when reflected from the surface of gold is yellow, and when transmitted through thin leaves of this metal is green; but when gold is reduced to a fine powder and suspended in water, the mixture will transmit, according to the state of division, blue, purple, or ruby light, as was shown by Faraday. Finely divided sulphur ordinarily transmits red light, but on precipitating it from a solution of sulphydric acid, and adding sesquichloride of iron, the liquid will for a short time transmit purple light. By decomposing sulphydric acid in solution with heat, the water holding the suspended sulphur appears blue. The theory now commonly received is that proposed by Sir David Brewster, namely, that when a body appears permanently of any given color, simple or compound, it is because it absorbs the remaining colors of the spectrum, *i. e.*, of the complete or white ray, and reflects those which constitute the color of which it appears. Thus a scarlet flower is a body having such relations to light that it absorbs violet, blue, &c., reflecting only certain proportions of red, orange, and yellow. In this view, bodies, as snow and milk, appear white when they reflect or transmit entire or white light; others, as certain inks and coal, appear black, because they absorb all the colored rays in the proportions which form white light. But as all bodies both absorb and reflect in some degree, the proportion of light which white bodies absorb and black bodies reflect is also a mixture of the various colors in the proportions forming white. To prove that the most intensely black body still reflects some light, look through a long narrow tube into a room completely darkened; this may be considered as presenting before the eye an absolutely black spot. Let a piece of coal or black velvet be brought against the inner end of the tube; the body is at once visible, as something differing clearly from the black space. Oersted separated the light coming from bodies into two parts. First, he found that all bodies have in some degree the property of mirrors, but that in those not polished the light is reflected from so many small surfaces in various directions that no image is produced. Secondly, he found that illuminated bodies gave out another portion of light not reflected, which had the proper color of the bodies themselves. A beam of light, in passing through certain media, or in being reflected from a surface at a certain angle, has all its vibrations reduced to a common plane, and is then said to be polarized. (See Light.) Arago proved that from illuminated unpolished bodies a small and usually imperceptible amount of light having the color of the luminary is returned to the eye, and that this light is polarized by reflection; while much the larger portion of their light, having the color of which the body is seen, is polarized by refraction, and hence must have come from beneath the surface of the bodies emitting it. A theory long since proposed in substance by Euler is explained at length in his "Letters to a German Princess." Two viols or other stringed instruments being attuned in unison, though many feet apart, if a string of one be made to give out a musical sound, the corresponding string of the other, being fitted to vibrate in the same times, takes up the vibrations from the air, and actually emits the same sound, or some chord of that sound. The first induces vibrations in the second; the second reciprocates the vibrations of the first; but the conditions of the second must first be suitable. In this view, when sunlight falls upon various bodies, it induces (according to the undulatory theory, by the communication of agitation from the ethereal medium to the molecules of the bodies) a luminous condition or power in the illuminated body, but which in most bodies remains only so long as the action of the original luminary is exerted upon them. But though the body receives the whole impulsion of white light, it will in turn reproduce the whole, or such part as the condition of its molecules fits it for reciprocating. If it reciprocate all the colored rays in due proportion, and in considerable amount, it will be white; if in like proportion, but in almost imperceptible amount, it will be called black. If a body re-

ciprocate mainly the blue and allied rays, it will be some shade of blue; and so of all colors. Moreover, whatever rays the molecular condition of the body forbids it to reciprocate, it will of necessity extinguish; but as force can no more be destroyed than matter, this extinguished light is not lost, but becomes manifest again as heat in the body receiving the rays, or perhaps in certain circumstances as affinity or electricity. According to Brewster's theory, a body is exactly of the color which it rejects, or does not possess; according to Euler's, the body is of the color it shows, and color is not a quality of light merely, but a secondary physical quality of bodies, due to a primary mechanical one. Thus a white body, as a screen, can respond to any color thrown upon it; but a colored body can only respond to rays within a certain limit, and if it receive rays only of colors beyond this limit, it must appear black. In the undulatory theory, as now received by the highest authorities in physics, there is assumed to be a fixed and invariable connection between the color of a given ray and its refrangibility; and the latter again depends on its rate and time of vibration. Thus, as calculated by Dr. Young, the middle red ray has a wave length of $\frac{1}{39,180}$ of an inch, and corresponds to 477 millions of millions of pulsations per second of the ether, or of the retina; while the middle violet has a wave length of $\frac{1}{57,490}$ of an inch, and corresponds to 699 millions of millions of pulsations per second; the other colors having wave lengths intermediate to these. Sir David Brewster, however, who set out with a partiality for the now exploded corpuscular theory, examined the spectrum with variously colored glasses, and declared that he detected some red, yellow, and blue in all parts of it. He accordingly proposed a theory of white light as composed of three elementary colors only, those just named; each color having all the various degrees of refrangibility, and the other colors being mixtures of these three. Helmholtz has shown that many of Brewster's results were due to using imperfect prisms, and that when these sources of error are in a high degree removed, the mixture of rays through the spectrum fails to appear.—*Complementary Colors.* Solar or white light being regarded as a whole produced by the union of many elements (colors), it is plain that any portion of these elements being blended to form a composite hue, the remainder will form by mixture some other hue; and either of these being added to the other, the result will be the reproducing of complete or white light. In mathematical language, that which by addition to any part completes it, or makes a whole, is termed a complement. Transferring the mathematical conception to light, any hue, simple or compound, so related to another that by blending it produces with the latter white light, is termed its complementary color, and *vice versa.* Suppose the four higher prismatic colors blended; their dominant hue is blue. If now the three lower colors, red, orange, and yellow, be mingled in a separate hue, this will be an orange-red. But this combined with the compound blue just named must produce complete or white light. Hence, in the particular hues of each thus obtained, blue and orange-red are complementary; but there may be many slight variations of these hues which shall go by the same names, and yet not be exact complements, the result of their mixture being then a white tinged with whatever color happens to be in excess; *i. e.*, a light tint of that color. All the colors but yellow and green being blended give a hue of violet-red; and of this the yellow-green is complementary. If one of the compound hues be varied by the incorporation of more of a certain element, the other must lose an equivalent of the same element. If the yellow-green be moved toward green by adding blue, the violet-red, in order still to be complementary, must be moved toward red, by losing the same amount of blue as the other gains. If one of the hues be, irrespective of light or shade, increased in intensity, the other must also be made more intense; since, if the relative quantities of each color existing in the normal spectrum be not maintained, an uncompensated portion of one or more colors must remain. The following pairs of colors are complementary to each other: Red—bluish-green; orange—blue (azure); yellow—indigo; green—reddish-violet; blue—orange-red; indigo—orange-yellow; violet—yellow-green. M. Chevreul, superintendent of the dyeing department of the Gobelins manufactory, constructed a chart of 24 hues, each shown in 24 different tones, and so arranged that not only the composition and relations, but also the complementary color of each of these, are obvious at a glance.—*Subjective or Accidental Colors.* Place on a sheet of white paper a red wafer, and look on it intently for some seconds; move the wafer suddenly away, and in its place is seen a bluish-green spot of sensibly the same size. After looking at an orange wafer an azure image will appear; indigo will follow yellow, and violet succeed yellowish green, and the reverse. The color of the image is in all cases complementary to that of the original object. If small objects of any colors be well illuminated and viewed on a black ground, the complementary image is seen upon closing the eyes. Under the same circumstances, a white object will give a black image. The color thus following upon the contemplation of its complement has been termed accidental, and also, from the fact that it arises from some state produced within the visual organ itself, subjective. A complete account of the ordinary phenomenon may be summed up thus: The color of the object itself grows gradually more faint, as it is viewed; after the cessation of the direct action of the object on the retina, there is, 1st, the persistence for about $\frac{1}{10}$ of a second of the primitive

impression; 2d, the appearance of the accidental image; 3d, the permanence for a longer or shorter period of the latter, its intensity and duration depending on the intensity and time of the direct impression, while the color gradually fades and then gives place to others; or if the eyes be successively opened and shut, or directed to light and dark surfaces in turn, a succession of appearances and disappearances of the image, usually attended with changes of its color. Any one may witness these curious results by taking a momentary glance at the sun or a candle flame, or looking steadfastly on a strongly lighted colored object, and then proceeding as already indicated. The subjective color obtained from the red sun of morning or evening will be a hue of green, passing, if the eyes be kept closed, gradually to darker hues, as blue and violet, or restored to red by looking momentarily on a white surface, and then followed by green on closing the eyes; that obtained from the yellowish-white sun of midday will be indigo or violet. In either case, if the eyes are turned at once to a white surface, the image at first appears of its darkest color, passing successively through the lighter colors to white; and whatever color appears when the eyes are closed, its complementary is seen when they are fixed on a white surface. Place, again, any small colored object upon a white surface, and look on it for some time: colors will be seen to develop themselves about the edges of the object, the color being in each case the complement of that of the object, bluish green surrounding red, and so on. The general explanation of these phenomena is, that the retina, having been once impressed with any color, gradually loses its sensibility to that color, and acquires a disposition to be affected by its complementary; and that this tendency is manifested both successively, or in time, and simultaneously, or in space. M. Scherffer considers that the continued or powerful action of certain colored rays enfeebles or fatigues the sensibility of the retina to those rays; so that when the eye afterward receives white light, it is affected for a time by the other or complementary rays only. M. Plateau explains both the persistence of the original, and the appearance and changes of the successive accidental colors, by supposing these changes to constitute the transition in time of a portion of the retina from an excited to its normal state; while irradiation and the simultaneous accidental color constitute a similar transition in space, or from the actually excited portion of the retina to that which is in repose. When we look continuously on any color, as red, this color loses its vividness and beauty, because a color the opposite of red is excited in the eye, and blends with it; but its complementary, or any color near to this, as green, being now presented, the latter is at once improved, rendered more pure and vivid, by the acquired tendency of the eye to see that color. This is successive contrast; and it is thus shown that colors which will harmonize, or affect the eye agreeably, and be mutually improved, by being viewed in succession, are opposites or complements of each other. Colors nearly allied will be injured when thus beheld, and will affect the eye unfavorably. A purchaser who is shown in succession several pieces of bright red cloth will pronounce those last seen to be much inferior in brightness and beauty of color to the first; but if his attention be now directed to green stuffs, he will declare these extremely bright; and after them will see red stuffs quite as favorably. Again, two hues of red or blue seen side by side are not improved, because the impression made by either tends to excite an impression of green or orange in its neighborhood, which impression blends with the actual color of the other piece, and impairs it. But if blue and orange strips be viewed side by side, the blue throws orange upon the orange, and *vice versa*, so that the brilliancy and purity of both colors are improved. This effect constitutes simultaneous contrast; and it shows that harmony in colors viewed at once and near to each other also requires that these should be, or approach to, complementaries of each other. If different tones be associated, the effect is always to make the tinted appear lighter, and the shaded darker, than it really is. This is easily shown by placing side by side several gray strips, passing gradually from quite light to dark; although the shade of each strip is homogeneous, yet its side toward a darker strip will appear to be the lighter, and that toward a lighter strip the darker. Chevreul's law, both for hues and tones, deduced from facts such as those now stated, may be thus expressed: "When the eye sees at the same time two contiguous colors, they will appear as dissimilar as possible, both in optical composition and in height of tone. Guided by this principle, the juxtaposition of colors in painting, in dress, in furniture, in the planning of gardens, in bouquets, and indeed wherever colors are employed with a view to artistic effect, ceases to be a matter of accident or an ill-understood experience, and becomes a subject for the rules and predictions of science. In all chromatic arrangements, harmonies of contrast are first to be sought. But as these are limited, harmonies of analogy are also called into requisition, with less striking, but often with very pleasing results. These may be secured in three ways: by arranging different tones in a series; by associating nearly related hues of a like tone, except where these, as blue and violet, distinctly injure each other; and by viewing appropriate groupings of colors by colored light, as that from a stained window, which modifies them all in a particular direction. The effect of the contiguity of white is to deepen all hues in whatever tone, unless it may be a light yellow; but with the deeper hues and tones, the contrast with white is generally too violent. Black accords well with almost any hue or tone, except that the deeper, as indigo or violet, render

it apparently gray and faded.—The reader is referred to M. Chevreul's work on this subject, or to Prof. Youmans's "Household Science," for full details in relation to the arrangement or matching of colors. A few examples may be given. Thus, to trim orange articles of dress with yellow, to bring violet and deep blue flowers into juxtaposition, to upholster mahogany chairs with crimson or dark orange stuffs, without an intervening band of black or green, or to place heavy gilt frames near to strong red or orange in a picture, is a violation of chromatic harmony. Black and dark colors diminish, white and lighter tones enlarge, the apparent size of the wearer. Large figures or horizontal stripes shorten, while narrow vertical stripes heighten, the apparent stature. All colors in the vicinity of the face influence the complexion, as already explained. Hues and tones of green improve a pale or blonde complexion, by throwing on it their complement of rose; while orange throws blue on the too abundant orange of the brunette complexion, and blending with the latter produces a whitening effect. Light or tinted colors agree best with light, deep or shaded colors with dark complexions. Carpets, paper hangings, curtains, and furniture for rooms should be of colors chosen with reference both to their effects upon each other, and upon the complexions of the inmates. The beauty of red flowers is heightened by the neighborhood of green foliage; and in the hues of flowers it is easily observed that chromatic discords are seldom met with. The association of a yellow or orange pollen with a violet, purple, or blue corolla is familiar. An eye delicately susceptible to colors will note also the frequent examples of modification of color by contrast, that come under daily observation. Thus an orange-red sunset appears heightened to bright scarlet when seen through openings in green foliage; narrow bands of gray clouds moving over such a sky appear of a rich light or olive green; and at a later hour, when the distant forest is simply black, it appears bordered at the top with a vivid green from the same cause. One who looks intently at a bright horizon will see after some seconds a dark curtain appear to drop down to near the horizon, while between this and the earth a brightened band of sky of changing width will be visible. The colors of thin plates and films, as mica, mother-of-pearl, and soap bubbles, and similar phenomena, are treated of in the article LIGHT.

COLORADO, a territory of the United States, bounded N. by Wyoming territory and Nebraska, E. by Nebraska and Kansas, S. by the Indian territory and New Mexico, and W. by Utah. It is situated between lat. 37° and 41° N., and lon. 102° and 109° W., forming nearly a parallelogram; average length E. and W., 380 m.; breadth N. and S., 280 m.; area, 104,500 sq. m. It is divided into 21 counties: Arapahoe, Bent, Boulder, Clear Creek, Conejos, Costilla, Douglas, El Paso, Fremont, Gilpin, Greenwood, Huerfano, Jefferson, Lake, Larimer, Las Animas, Park, Pueblo, Saguache, Summit, and Weld. The principal cities and towns are: Denver, the capital and chief city, in Arapahoe co., pop. in 1870, 4,759; Central City, 2,360, and Black Hawk, 1,068, in Gilpin co.; and Georgetown, Pueblo, Golden City, Trinidad, Greeley, Kit Carson, Boulder City, Cañon City, and Colorado City, with populations less than 1,000. According to the United States census, the population in 1860 was 34,277; in 1870, 39,864, which included 456 colored persons, 7 Chinese, and 180 Indians. The tribal Indians of Colorado are the Tabequache band of Utes, at the Los Pinos agency, numbering 3,000 in 1872, and the Yampa, Grand River, and Uintah bands of the White River agency, numbering 800. They have a reservation of 14,784,000 acres, extending from the S. boundary of the territory to 15 m. N. of the 40th parallel, and from the 107th meridian to the W. boundary. The White River agency, on the river of that name, is in the N. part of the reservation; the Los Pinos agency is in the S. E. part. These agencies are under the charge of the Unitarians. At the White River agency there is a school attended by 40 scholars. These Indians receive annuities in goods, clothing, &c., of $40,000, and a like sum in subsistence. There are also a few Indians roaming in the E. part of the territory. Colorado ranks fourth among the territories in point of population. The number of male citizens of the United States in 1870, 21 years old and over, was 15,515. Of the total population, 24,820 were males and 15,044 females; and 33,265 were native and 6,599 foreign born. Of the natives, 6,344 were born in the territory, 8,378 in New Mexico, 1,812 in Illinois, 809 in Indiana, 1,310 in Iowa, 1,704 in Missouri, 621 in Massachusetts, 2,778 in New York, 2,057 in Ohio, and 1,552 in Pennsylvania; of the foreigners, 1,685 were born in Ireland, 1,456 in Germany, 1,358 in England, and 753 in British America; and 1,235 persons born in the territory were living in other states and territories. The number of families was 9,358; of dwellings, 10,009. There were 6,297 persons 10 years old and upward unable to read; 6,823 were unable to write, of whom 255 were foreigners, and 2,368 were males and 2,122 females 21 years old and over. There were 26 blind persons, 4 deaf and dumb, 12 insane, and 3 idiotic. The homicides during the year were 37, 4 of which were by Indians. There were 6,462 engaged in agriculture, 3,625 in professional and personal services, 4,681 in manufactures and mechanical and mining industries, and 2,815 in trade and transportation. —Colorado has three natural divisions: the mountain range, including the park system, the foot hills, and the plains. The territory is intersected N. and S. near the centre by the Rocky mountains, which here attain their greatest elevation, 200 peaks nearly 13,000 ft. high and about 25 of 14,000 ft. and over being visible from Mt. Lincoln. Between lat. 38° 30′ and 40° 30′ the chain is about 120 m. broad,

consisting of three parallel ranges running nearly N. N. W. The E. one, called the Front or Colorado range, as seen from Denver, appears to rise abruptly from the plain, stretching with snow-capped summits from Pike's peak on the south to a group 20 m. N. of Long's peak, a distance of 120 m. Six of its peaks are from 14,000 to 14,200 ft. above the sea, viz.: Long's peak, Mt. Torrey, Gray's peak, Mt. Rosa, Mt. Evans, and Pike's peak. W. of this range lie the parks, separated from each other by comparatively low or broken cross ridges; and parallel with it and about 40 m. further W. is the Park range, forming the W. boundary of North, Middle, and South parks. Its highest points are in the Mt. Lincoln group, near the dividing ridge between South and Middle parks; 20 peaks exceed 13,000 ft. in height, and Mt. Lincoln and Quandary peak rise above 14,000 ft. The Blue River group lies 20 m. N., having many peaks of 13,000 ft., and the culminating points reaching 13,300 ft. The northernmost and highest summit is Mt. Powell, beyond which there are no high peaks to North park; opposite this an altitude of 12,000 ft. and over is attained. W. of the S. part of the Park range is the Arkansas valley, and beyond this is the National range, also called the Sawatch range or Sierra Madre, dividing through nearly its whole extent the waters of the Atlantic from those of the Pacific. It is parallel with and about 16 m. W. of the Park range, terminating some 40 m. N. W. of Mt. Lincoln in the mount of the Holy Cross, about 13,400 ft. high. The highest part of this range commences in Grand mountain, about 14,200 ft. above the sea, 20 m. S. of the Holy Cross, whence for 50 m. further S. the whole range is 13,000 ft. high, with 10 peaks rising at intervals of from 5 to 8 m. to a height of from 14,000 to 14,400 ft. The principal summits are Mts. Elbert, La Plata, Harvard, and Yale. W. of the National range and connected with it are the Elk mountains, lying between the Grand river on the north and the Gunnison on the south. The most elevated peaks form a ridge about 30 m. long, nearly parallel with the National range and 35 m. W. of it. At the N. end of this ridge, in lat. 39° 15′, is Mt. Sopris, 13,000 ft. high, S. of which are the Capitol (14,100 ft.), the White House (14,050 ft.), and Maroon mountain and Castle peak, each 14,000 ft. high. W. of this group there are no high mountains, the ridges changing within 20 m. to plateaus, which fall off to the Colorado river. The "timber line" of the ranges, the highest point at which timber grows, is determined by the lying snow, and varies from 11,000 to 12,000 ft. On the E. side of the mountains and parallel thereto, extending from the Black hills on the north to the Wet mountains on the south, are the foot hills, having an average elevation of 8,000 ft. The Wet mountains branch out from the main range S. of Pike's peak, and extend in a S. E. direction to the Huerfano river. Between the Huerfano and Purgatory rivers are the Spanish peaks, an independent series of mountain cones. The Raton mountains, running in an E. direction from the main range, form the S. base of Colorado. W. of the main range, in the S. portion of the territory, the Sierra San Juan extends nearly N. and S., forming the W. wall of San Luis park. The Rio Grande forms the N. and E. limit of this range. The Sierra la Plata, also S. of the Rio Grande, extends W. from the San Juan range to the S. W. boundary. The S. W. portion of Colorado is traversed by the Uncompahgre mountains, extending W. from the Sawatch range, and forming the divide between the Rio Grande and the principal southern tributaries of the Colorado. The Sierra San Miguel forms the extreme S. W. portion of the series of ranges extending W. from the main range in southern Colorado. The Roan or Book mountains are near the W. limits of the N. portion of the territory, between the White and Grand rivers. The N. W. corner is occupied by the Sierra Escalante. The "plains" constitute the geographical division of Colorado E. of the mountain belt, and embrace more than one third of the entire territory. The surface of this section is not one continuous level, but a series of valleys separated by ridges and traversed by innumerable watercourses. The average elevation above tide water is about 6,000 ft. The most prominent feature of this vast plateau is the "divide," an elevation reaching a height of 7,500 ft. above the sea level, which separates the waters of the South Platte and Arkansas, and supplies many of their affluents. It branches out from the foot hills N. of Pike's peak, and gradually slopes N., S., and E. into the general level of the plains. The numerous swift streams, having their sources in elevated regions and flowing in various directions, render irrigation practicable, except in the E. central portion of the plains, where the streams are too remote.—The most remarkable physical characteristic of Colorado is its park system. The parks consist of extensive irregular plateaus or basins shut in on all sides by lofty mountain ranges. The surface of these plateaus is diversified by numerous hills or ridges and valleys, containing streams which form the head waters of all the great rivers that rise in Colorado. These valleys are clothed with luxuriant grasses and flowering plants of various species, and possess an extremely fertile soil. The hills are covered with dense forests of pine, abounding in game, such as the bear, elk, and deer. The beds of the streams furnish many varieties of minerals and fossils, and afford a remarkable field for geological investigations. Mineral springs, with waters possessing rare medicinal properties, are numerous, while salt and coal beds seem to underlie the entire surface. The four principal parks are in the central portion of the territory, and constitute the greatest part of a belt running N. and S. between lon. 105°

30′ and 106° 30′ W. The most northerly is North park, which embraces an area of about 2,500 sq. m., and has an elevation of nearly 9,000 ft. above the level of the sea. It is traversed by affluents of the north fork of the Platte, which unite near its N. limits, and flow N. beyond the borders of Colorado. Next to this, on the south, and separated from it by mountain spurs, is Middle park, walled in by the Front range of the Rocky mountains on the E., and on the W. by the Park mountains. It embraces an area of about 3,000 sq. m., extending about 65 m. N. and S. and 45 m. E. and W., and is also about 9,000 ft. high. The streams, most of which flow in a S. W. direction, are all tributaries of the Grand. On a tributary of this river, about 12 m. from the S. boundary of the park, are the hot sulphur springs, whose valuable medicinal qualities have attracted the attention of invalids and tourists. S. of Middle park, on the E. side of the Park range, is South park, embracing within its rocky barriers about 2,200 sq. m., the greater portion of which is adapted to agriculture, and nearly all of which affords excellent pasture lands. The maximum elevation above the sea is 10,000 ft., while the average elevation is about 9,000 ft. The streams, which are supplied by melting snows from the surrounding mountains, are tributaries of the South Platte, and flow E. through the park to the plains. The largest of these parks is San Luis, which has an area not less than that of the other three combined. It lies S. of South park, from which it is separated by the main range, which forms its N. and E. boundary, while its W. boundary is formed by the Sierra San Juan. Its highest elevation does not exceed 7,000 ft., which, with its southern location and mild climate, makes it well adapted to agriculture. The park is watered by the Rio Grande and its numerous tributaries, which flow in a southerly direction, and afford abundant water power. Other smaller parks, presenting similar features, are scattered through the mountains W. of the main range. Of this vast region little is known.

—The river system of Colorado embraces the principal tributaries of the Rio Colorado, Rio Grande, Arkansas, Platte, and Smoky Hill and Republican forks of the Kansas. The Arkansas rises at the base of Mt. Lincoln, on the W. slope of the Rocky mountains, flows S. E. along the base of the range, W. and S. W. of South park, and, in a deep cañon, passes through the range at Cañon City, whence it continues across the plains in a S. E. direction. It traverses in Colorado a distance of about 500 m., no part of which is navigable. Its principal tributaries on the south are: the Greenhorn, which rises in the Wet mountains, flows N. E., and joins the main river a few miles E. of Pueblo; the Huerfano and its branch, the Cuchara, which unite about 18 m. from the Arkansas; the Apisha, which rises in the Spanish peaks, and flows into the Arkansas about midway between Pueblo and Fort Lyon; the Purgatory, which rises from the S. and W. declivities of the Spanish peaks and the N. slopes of the Raton mountains, and flows in an E. and N. E. direction; and the Cimarron, which rises on the S. slope of the Raton mountains, flows E. to the S. E. corner of the territory, and reaches the Arkansas in the Indian territory. The principal northern tributaries of the Arkansas are Fontaine qui Bout, which flows in a S. direction from the N. base of Pike's peak, near the foot of South park, joining the main river at Pueblo; Squirrel creek, the Little Sandy, and Big Sandy, flowing S. E. from the divide to the Arkansas. N. of the divide, the E. slopes of the mountains are drained by the South Platte and its tributaries. This river rises near the foot of Mt. Lincoln, in the N. W. corner of South park; it flows in a S. E. direction, receiving numerous smaller streams from the surrounding ranges and spurs, and leaves the park about 70 m. N. of the base of Pike's peak. After passing through the foot hills, it pursues a N. course for over 100 m. to the junction with its branch, the Cache à la Poudre, whence it flows E. and N. E. until it leaves the territory at its N. E. corner. The principal tributaries of the South Platte from the mountains have an E. direction, and join the main river before its confluence with the Cache à la Poudre, which also rises in the mountains N. of Long's peak. Beginning from the south, they are: the North fork of the South Platte; Clear creek, which, rising near the base of Gray's peak, flows through Clear Creek and Gilpin counties; St. Vrain, and Big Thompson. Flowing into the South Platte from the divide are Plum, Cherry, Terrapin, Kiowa, Bijou, and Beaver creeks. From the N. limits of the territory, flowing in a S. direction into the South Platte, are the Crow, Pawnee, and Horse Tail creeks. The Smoky Hill and Republican forks of the Kansas rise in the E. central portion of the plains, and pursue an E. direction to the limits of Colorado. The region W. of the main range, and N. of the Uncompahgre mountains, is drained by the tributaries of the Rio Colorado and the head waters of the North fork of the Platte; the latter are in the North park and surrounding mountains and flow northward. The principal northern tributaries of the Colorado are Bear river, flowing W., which has numerous branches rising in Elk Head, Rabbit Ears, and Escalante mountains; White river, which rises in the N. W. part of the territory, and flows W. until it empties into the Green, a tributary of the Colorado in the N. E. part of Utah; and Grand river, which rises near the base of Mt. Lincoln, and, receiving numerous tributaries from Middle park and the surrounding mountains, flows W. to its confluence with the Gunnison (also called the South fork of the Grand), near the W. central border of Colorado; its course is exceedingly tortuous, winding around mountain bases, and forming cañons of unknown

depth in the rocky barriers. The Gunnison rises in the Sawatch and Uncompahgre mountains, and pursues a N. W. course, through a continuous series of mountain chasms, to its confluence with the Grand; it has numerous tributaries. The Rio San Miguel and the Dolores rise in the San Miguel and La Plata mountains, flow N. W., and after uniting fall into the Grand. The Rio Grande rises in the S. W. part of the territory, E. of the Sierra La Plata, flows E. about 150 m., then bends abruptly, and pursues a S. course through the middle of the San Luis valley. Along the S. W. border of the territory are numerous streams which flow S. to the San Juan in New Mexico. On the plains many of the smaller tributaries of the Arkansas and the Platte disappear in the sands during the greater portion of the summer.—E. of the main range of mountains, a portion of the country N. of the divide has been to some extent geologically examined. Denver is situated on the tertiary rocks which contain the coal beds of the west. The rocks here are thickly covered with superficial drift. Passing S. up the valley of the South Platte, the tertiary sandstones are occasionally exposed in the banks of the river. About 12 m. S. W. of Denver are some remarkable soda lakes, resting on middle cretaceous rocks. From these lakes to the great divide the cretaceous and tertiary beds are concealed by superficial gravel and sand. On each side of the divide, beds of whitish-yellow and reddish sandstones appear, holding a nearly horizontal position. In the N. part of Colorado, near the E. base of the mountains, beds of tertiary coal have been found. The main range of mountains, particularly the gold and silver lodes, is composed of gneissic and granitic rocks. In the mountain valleys are immense deposits of modern drift. Bowlder drift is conspicuous in the mountains that wall in South park on the N. and N. W., while along the W. and N. sides appear lofty eruptive peaks, which seem to be old volcanoes. The mountains E. of the park have a gneissic and granitic nucleus. Within the park sedimentary rocks are found, and there are also salt springs and deposits of gypsum. The portion of Colorado W. of the main range of mountains forms part of the great volcanic basin which stretches S. into New Mexico, and N. W. into Utah and Idaho territories. In this region are many extinct volcanoes. The lava rocks which abound are not usually metalliferous, though they contain much mineral glass (obsidian). During the process of liquefaction which these rocks have undergone, vast areas, which now resemble lakes of black solidified sea water, have in some instances been submerged by the liquid overflowing from fissures hundreds of miles in length. The technical name of this formation is *pedrigal*, while the rocks are called *malpais*. The Rio Grande, from its source to beyond the limits of Colorado, flows through a *pedrigal* of extraordinary dimensions. In Middle park all the sedimentary rocks known in the country are found. Carboniferous beds are probably wanting, but the triassic, Jurassic, cretaceous, and tertiary are well developed. There are two groups of tertiary deposits: the lignite, or older tertiary, and the modern pliocene marls and sands. Grand river, just above the hot springs, passes through a high ridge of basalt, which has the lignite tertiary beds above and the cretaceous shales beneath. The tertiary rocks are of great thickness, and are composed mostly of fine sandstone and pudding stone. At the Grand cañon, just below the hot springs, the river cuts through a ridge of massive feldspathic granite for a distance of 3 m. between high walls.—Vast deposits of useful minerals of almost every kind occur in nearly every portion of Colorado. The most important of these are gold and silver, which are found in large quantities in a belt about 50 m. wide stretching N. and S. across the central portion of the territory. Gold occurs in lodes, or fissure veins, having a N. E. and S. W. direction, and in gulches or in placers; the latter being superficial deposits which have been washed from mountain summits and slopes to the plateaus, gulches, and valleys below. The veins occur in groups, often presenting the most complicated network on the surface. These groups are usually one or two miles in width and two or three in length, and there may be two or three distinct groups abreast of each other. The principal gold-bearing minerals are copper and iron pyrites. These mostly occur together; the latter, however, nearly always predominates, and is often found without the former. When both are present, the copper pyrites is always the richer in gold. These ores assay in bulk from $30 to $40 per ton. About 70 per cent. of the gold bullion is extracted from the ores of Gilpin, Clear Creek, Boulder, Park, and Lake counties, 50 per cent. or more being furnished by Gilpin county, the bullion shipped from which for the year ending July 1, 1870, amounted to $1,378,100. The deposits at the branch mint at Denver for the year ending June 30, 1872, amounted to $1,001,564 81, of which $16,336 54 were silver. The total deposits of gold which had been made at this office up to June 30, 1872, amounted to $5,552,371 69, of which $4,985,754 67 were the product of Colorado. According to official mint returns, the deposits of gold from Colorado at the United States mint, branches, and assay offices, up to June 30, 1872, have been as follows:

YEARS.	Value.	YEARS.	Value.
1859.....	$4,171 70	1867.....	$1,026,276 83
1860.....	599,846 30	1868.....	1,081,040 16
1861.....	2,091,197 17	1869.....	1,652,492 21
1862.....	2,035,416 50	1870.....	1,551,102 81
1863.....	2,893,336 87	1871.....	1,495,035 66
1864.....	2,136,684 69	1872.....	1,176,518 09
1865.....	1,622,249 45		
1866.....	1,018,052 52	Total	$20,338,420 96

Reckoning the deposits at one third of the total product of the mines, the total yield of gold for the territory to June 30, 1872, was more than $60,000,000. For the extraction of the gold, the common stamp-mill process, with amalgamation in battery and upon copper plates, is now almost exclusively employed, although it is generally admitted that only a portion of the precious metals is secured in this way. According to the best statistics attainable, which are somewhat imperfect, the number of stamp mills in Colorado in 1870 was 105, with more than 1,800 stamps. Of these mills, 94 for the reduction of gold, with 1,607 stamps, of which 857 were in operation, were in Gilpin county, and the remainder in Clear Creek, Boulder, Park, and Lake counties; and 4 for the reduction of silver, with 70 stamps, in Clear Creek county, and 2 for the reduction of gold and silver in the same county. Although the discovery of silver in Colorado dates as far back as that of gold, it is only within a few years that rich deposits of this metal have been known to exist in the lodes of the mining counties. The silver ores have been divided into surface and galena ores. The former generally contain, besides more or less zinc blende, a little decomposed galena and sulphuret of silver; and very often the zinc blende is also decomposed. With increasing depth the amount of galena and zinc blende gradually increases, until at a depth not exceeding 100 ft. they decidedly predominate. The principal silver-producing county is Clear Creek. The actual development of the prominent silver lodes was begun in 1867; the whole amount of ore mined up to April 1, 1869, is estimated at 1,100 tons, which yielded $250,000 in coin. The production of silver ore in Clear Creek county amounts to about 2,000 tons per annum. The estimated yield of silver, including shipments of ore, during 1870, was about $400,000. The deposits of silver from Colorado at the United States mint, branches, and assay offices, to June 30, 1872, have been:

YEARS.	Value.	YEARS.	Value.
1866.....	$419 00	1871.....	$367,510 31
1867.....	543 78	1872.....	264,821 18
1868.....	46,881 13		
1869.....	197,678 54	Total.....	$1,114,543 43
1870.....	236,689 49		

The following statement made by E. E. Burlingame, Feb. 17, 1871, shows the coin value per ton of 2,000 lbs. of specimens of ore from different districts of Gilpin and Clear Creek counties:

	SAMPLES.	Gold.	Silver	Total.
Gilpin.	35, of smelting ore, 1st class.	$138 92	$30 32	$169 24
	32, " " "	90 30	37 62	127 92
	28, " " "	50 28	61 90	112 18
	72, of mill ore, 2d "	24 10	11 37	35 47
	56, " " "	22 51	12 85	35 26
	59, " " "	20 07	17 14	37 21
Clear Ck.	18, of smelting ore, 1st "	18 44	228 90	247 34
	22, " " "	.....	409 81	409 81
	39, of mill ore, 2d "	7 82	35 97	43 79
	34, " " "	.....	86 31	86 31

Iron pyrites is universal in the mines, occurring in cubes from the size of a pin's head to an inch on the sides. Copper, almost always in the form of pyrites, occurs in the prominent lodes in considerable quantities; the first class ores of some of the mines contain from 10 to 15 per cent. of it. Besides copper and iron pyrites, almost every lode contains a little zinc blende and galena; in some districts these minerals form a considerable part of the ore. Large beds of lignite, pronounced superior to any other found in the west, occur on the E. declivity of the mountains, in Boulder and Jefferson counties. The coal obtained resembles anthracite in appearance, but burns with a strong yellowish white flame, gives little soot, and from 2 to 3 per cent. of ashes of a reddish yellow color. It has been found in veins 14 ft. thick, of which 13 ft. are workable coal. The value of these beds of lignite is greatly enhanced by the simultaneous occurrence of fire clay and iron ore. The former, found in layers from 3 to 5 ft. thick between the different strata of coal, is of a grayish blue color, burns almost white, and compares favorably with the standard clays of Europe. Lignite is also found in the vicinity of the Raton mountains near Trinidad, and in the Arkansas valley E. of Cañon City. The iron ore occurs, scattered over the surface, all the way from South Boulder to Coal creek. At a depth not exceeding 5 ft. masses of 1,000 lbs. have been found in the sand; and though no defined bed has yet been discovered, the great quantity of superficial bowlders indicates that such a deposit exists. The ore yields from 50 to 60 per cent. of iron. Salt springs occur in South park, where extensive works have been erected. Valuable soda springs exist near the base of Pike's peak, and in other portions of Colorado. Hot sulphur springs, possessing valuable medicinal qualities, occur on a tributary of the Grand, in Middle park, about 12 m. from its S. boundary.—The climate of Colorado is remarkably equable and healthy. The winters are mild, and the summers cool and bracing. Hot, sultry nights are unknown. On the plains the temperature averages from 50° to 55°. At Denver during 1870 the mean temperature for each month and the amount of rain and melted snow were as follows:

MONTHS.	TEMPERATURE.			Rain and melted snow, inches.
	Max.	Min.	Mean.	
January.....	60°	5°	29·4°	1·15
February.....	64	1	35·5	1·70

The average temperature for 1871 was 54·1°; rainfall, 12·35 inches. For 1872 the average temperature was 49·8°; rainfall, 18·77 inches. The average temperature of the foot hills is from 45° to 50°, and of the mountains from 40° to 45°. On the summits of the mountain ranges and in the higher parks the cold is often extreme; but in the mountain valleys and foot hills the thermometer seldom falls below zero, and in midwinter there is much delightful weather. The greatest extremes of cold and the most severe storms occur in November and December. In the mountains the greatest fall of snow occurs in September, October, and April; except on and near the summits, where the fall is considerable, it does not remain long on the ground. On the plains, in the latitude of Denver, the fall of snow never exceeds 10 or 12 inches, and seldom remains longer than 24 hours. In the S. portion of the plains there is little snow, and the winters are very mild. There is no rainy season in Colorado. On the plains the rains generally fall in the spring and early summer, scarcely any falling in autumn or winter. In the mountains, rains are frequent in the summer and autumn, but rain storms of long duration are unknown. Heavy wind storms are common in all parts of the territory. The extreme rarity of cloudy weather and of mists and fogs is remarkable. The atmosphere is wonderfully clear and invigorating, and remarkably free from humidity. These characteristics of climate, together with the great altitude, 4,000 to 10,000 ft., and the beautiful scenery, have made Colorado a resort for persons afflicted with throat and lung diseases, who derive much benefit from a residence here. In 1870 there were 375 deaths, of which 32 occurred from consumption.—About one third of Colorado is good agricultural land. In the plains and the parks the soil of the valleys is peculiarly fertile, and produces in abundance the hardier cereals and vegetables. The arid sands of the plains have been proved to be merely surface deposits, covering a soil of remarkable fertility when moistened. The necessary moisture is supplied by irrigating canals, which have already been constructed to a great extent. The chief crops are wheat, barley, oats, and rye. The average yield of wheat is 25 bushels per acre. Except in the S. districts, the nights are rather cold for corn; but in the valleys of the Arkansas and tributaries 30 bushels per acre may be raised. Large crops of buckwheat and hay are produced; 500 bushels of potatoes have been obtained from a single acre. Vegetables grow to an enormous size. Apples, pears, plums, cherries, and grapes have been cultivated with great success; while it is not doubted that peaches, apricots, quinces, nectarines, &c., may be successfully raised. The grapes are of exquisite flavor and superior size, and the small fruits grow with remarkable luxuriance. But Colorado excels as a grazing and dairy country, deriving great advantages from the peculiarity of its nutritious grasses, upon which cattle thrive the whole year, and of which there is a great variety in the valleys and on the mountain sides. The uplands and ridges between the watercourses are covered with a short, crisp, drab-colored grass. These grasses are not destroyed by frosts, but, becoming cured during the winter months, retain their nutritious qualities, and afford excellent pasturage at all seasons. Except the parks and valleys, the vast region W. of the central mountain range is not suitable for cultivation, but pine forests and excellent pasturage abound. The principal varieties of timber are pine, hemlock, spruce, cedar, fir, cottonwood, box elder, and quaking aspen. The sides of the mountains below the timber lines and the foot hills are covered with forests of pine, larch, and aspen, which afford valuable timber and fuel.—The wild animals are the bear, couguar, wolf, buffalo, elk, deer, antelope, lynx, wildcat, badger, hare, fox, mink, pine marten, beaver, and prairie dog, the last resembling the fox squirrel. Of game birds there are the wild turkey, mountain grouse, sage hen, prairie chicken, ducks, geese, swans, ptarmigan, &c.—According to the census of 1870, the number of acres of improved land was 95,594; cash value of farms, $3,385,748; of farming implements and machinery, $272,604; total amount of wages paid during the year, including value of board, $416,236. The productions were 255,932 bushels of spring and 2,535 of winter wheat, 5,235 of rye, 231,903 of Indian corn, 332,940 of oats, 35,141 of barley, 178 of buckwheat, 7,500 of peas and beans, 121,502 of potatoes, 19,787 tons of hay, 890 lbs. of tobacco, 204,925 of wool, 392,920 of butter, 33,626 of cheese, and 19,787 gallons of milk sold. There were 6,446 horses, 1,173 mules and asses, 25,017 milch cows (and 6,871 not on farms), 5,566 working oxen, 40,153 other cattle (and 88,720 not on farms), 120,928 sheep, and 5,509 swine. Value of live stock, $2,871,102; of home manufactures, $57,658; of animals slaughtered, or sold for slaughter, $252,394; of all farm productions, including betterments and additions to stock, $2,335,106. The value of the agricultural products for 1872 was estimated at $4,650,000. The returns of the assessors to the auditor of the territory for that year show the number of horses to be 23,000; asses, 10,000; cattle, 243,000; sheep, 270,000; goats, 10,000.—There is an abundance of water power in Colorado, which has as yet been little utilized. The total number of manufacturing establishments reported by the census of 1870 was 256, having 49 steam engines of 1,433 horse power, and 31 water wheels of 792 horse power, and employing 876 hands. The capital invested amounted to $2,835,605; the wages paid during the year were $528,221; value of materials used, $1,593,280; value of products, $2,852,820. Besides quartz mills, the only important establishments are a few for the manufacture of iron, wool, and flour, which have recently been established at Denver.—Within a few years

railroad enterprise has been active in Colorado. The territory contained on Jan. 1, 1872, 392 m. of completed railroads. The lines in operation are as follows: the Denver Pacific, from Cheyenne, Wyoming territory, to Denver, 106 m.; the Kansas Pacific, from Kansas City, Mo., to Denver, 639 m.; the Denver and Boulder Valley, from Hughes, on the Denver Pacific, 18 m. from Denver, to Erie (to be extended to Boulder City, 16 m. further); the Colorado Central, which will open a line of communication between Denver and the mountain towns and cities (completed to Black Hawk, 38 m., with branches from Fork's Creek to Floyd Hill, 4 m., and from Golden City to Longmont, 41 m.); the Arkansas Valley, from Kit Carson on the Kansas Pacific to Pueblo (completed to West Las Animas); and the Denver and Rio Grande railroad, which will connect Denver with El Paso in Mexico (completed to Pueblo, 118 m., with a branch to Coal Banks, 38 m.). The following table shows the length of railroads in operation in the territory in 1873, with the capital stock and cost of construction of the entire lines so far as ascertainable:

LINES.	Length in the territory.	Capital stock.	Cost of road and equipments.
Denver Pacific..	96 miles.	$2,500,000	$5,000,000
Denver and Boulder Valley	15 "	.....	450,000
Kansas Pacific..	184 "	9,688,950	36,747,300
Colorado Central	88 "	1,474,300	3,300,000
Denver and Rio Grande.....	156 "	4,500,000	7,520,500
Arkansas Valley	56 "	.....	.....
Total.....	590 miles.	.....	.....

The Denver and Rio Grande was the first narrow-gauge railroad built in the United States. The gauge is 3 ft., the rails weighing only 30 lbs. to the yard. The maximum curvature is 6° in 100 ft., and the maximum grade 75 ft. to the mile. The use of this gauge has proved very successful, both from its effects in cheapening transportation, and its practicability over routes presenting insuperable obstacles to the construction of a wider road bed. A line of telegraph from Denver connects with the transcontinental line at Julesburg, Nebraska, and another connects Denver with Santa Fé, New Mexico. The entire length of telegraph lines in operation, Jan. 1, 1873, was 862 m. Colorado contains 6 national banks, with an aggregate capital of $575,000, of which 3, with a capital of $400,000, are in Denver; and 27 fire, 12 life, and 2 accident insurance companies have agencies in Colorado.—The government is similar to that of the other territories. The legislature consists of a council of 13 and a house of representatives of 26 members; its sessions are biennial. The election is held on the first Tuesday in October. The executive power is vested in a governor, secretary, treasurer, auditor, adjutant general, attorney general, superintendent of public instruction, and secretary of the board of agriculture. The salary of the governor is $2,500; secretary, $1,800; treasurer, $700; auditor, $1,000. The judicial power is vested in a supreme court, district courts, probate courts, and justices of the peace. The supreme court is composed of a chief justice and two associates, one of whom holds a district court in each of the three judicial districts into which the territory is divided. The supreme and district courts have general jurisdiction in law and equity. The salary of each judge is $4,500. The principal executive and judicial officers are appointed for four years by the president of the United States. The territory is entitled to one delegate in congress. There is no territorial debt. In 1870 the county debts amounted to $678,829, for which bonds had been issued to the amount of $620,000; town, city, &c., debts, $2,329. The total taxation not national was $362,197, of which $63,425 was territorial, $267,207 county, and $31,571 town, city, &c. In 1871 the internal revenue collections amounted to $69,993. In 1870 the assessed value of real estate was $8,840,811, personal $8,497,290; total assessed value, $17,338,101; true value of real and personal property, $20,243,303.—Colorado has a good school system, administered by a territorial superintendent and a county superintendent for each county, who are elected biennially by the people. There are also three directors for each of the districts into which each county is divided, elected annually. In 1872 the number of public schools was 175; teachers, 230; pupils, 5,640; value of school buildings, $180,645; amount of school fund, $121,372. The total expenditure for school purposes in 1871 was $98,105, of which $45,250 were for teachers' wages. High schools have been organized in a number of the chief towns. According to the census of 1870, there were 18 private schools, with 32 teachers and 516 pupils. There were 175 libraries of all classes, with 39,344 volumes; of these 30, containing 11,385 volumes, were public, of which 2 (2,000 vols.) were school libraries, and 22 (5,685 vols.) were connected with Sunday schools. The territorial library at Denver, which also contains a valuable collection of mineral specimens, had 2,600 volumes. There were 14 newspapers and periodicals, issuing 1,190,600 copies annually, and having an average circulation of 12,750. Of these 4 were daily, circulation 2,200; 9 weekly, circulation 9,550; and 1 monthly, circulation 1,000. The number of church organizations was 55; of church edifices, 47; sittings, 17,495; value of church property, $207,230. The principal religious denominations were:

DENOMINATIONS.	Church edifices.	Sittings.	Value of property.

—Colorado was organized as a territory by act of congress of Feb. 28, 1861, from parts of Kansas, Nebraska, New Mexico, and Utah. The portion N. of the Arkansas river and E. of the Rocky mountains formed part of the Louisiana purchase from the French in 1803; the remainder was included in the Mexican cession of 1848. The first well authenticated account of the discovery of what is now Colorado is the record of Vasquez Coronado, who under Spanish auspices commanded an expedition from Sinaloa, Mexico, in 1540. In 1806 the United States government fitted out an expedition for the purpose of exploring this region, under command of Lieut. (subsequently Major) Zebulon M. Pike. This expedition travelled from N. to S. in the mountain region nearly across the territory, and discovered the peak which has since been called Pike's peak from its commander. In 1820 another expedition, under command of Col. S. H. Long, visited this region; and in 1842–'4 occurred the celebrated exploration of Gen. (then Col.) John C. Fremont across the Rocky mountains. Before the commencement of the present century there is no record of any inhabitants in what is now Colorado, except in the S. portion, where a few Mexicans and Spaniards were settled. Besides these, before the discovery of gold, there were only a few American traders, hunters, and trappers in the region. Nothing definite was known of the existence of gold in the territory before 1852, when a Cherokee cattle trader discovered the metal near the mouth of what is now called Clear creek. The first person to organize a party to explore the mining district was W. G. Russell, a Georgian, who in 1858 found gold on Dry creek, about 7 m. S. of Denver. These discoveries were speedily known throughout the country, and about 400 persons had reached the mining region in the winter of 1858–'9. The first discovery of a gold-bearing lode was made by John H. Gregory, May 6, 1859, in what is now Gregory mining district, Gilpin county. The first act of the miners toward organizing a government was the erection of Arapahoe county, with Auraria as its county seat; soon after which, Nov. 6, 1858, they elected a representative to the Kansas legislature, and a delegate to congress, who was instructed to urge the separation of this district from Kansas, and the organization of a new territory. In the autumn of 1859 a convention of 128 members assembled at Denver, which decided to memorialize congress for a territorial form of government. Within a few years a number of colonies organized in the east have been established in Colorado; the most important of these is Union colony, at Greeley, on the Denver Pacific railroad. Since 1870 the population has rapidly increased. (See supplement.)

COLORADO, a S. E. county of Texas, comprising one of the best cotton-growing portions of the state; area, 905 sq. m.; pop. in 1870, 8,326, of whom 3,701 were colored. It has an abundant supply of timber, about one half the area being bottom land heavily wooded, or upland covered with post oak, live oak, &c. The soil is fertile and well watered by the Colorado and other streams. The Buffalo Bayou, Brazos, and Colorado railroad terminates at the county seat. The chief productions in 1870 were 130,423 bushels of Indian corn, 14,442 of sweet potatoes, and 2,796 bales of cotton. There were 2,751 horses, 4,370 milch cows, 26,125 other cattle, 2,987 sheep, and 6,280 swine. Capital, Columbus.

COLORADO, a river of Texas, rising in Bexar district, between the 32d and 33d parallels, about lon. 102° W. It flows successively S. E., E., S., and again S. E., and empties into Matagorda bay. Its length is over 900 m.; average width 250 ft. The only important tributaries are in the upper part of its course, where it receives from the S. W. the Rio Concho, San Saba, and Llano, and from the N. W. Pecan bayou. In winter it is navigable for steamboats to Austin. It flows for more than two thirds of its length through a highly fertile region, and is a beautiful clear stream. It owes its name to an interchanging of the names of Colorado and Brazos, which the first discoverer bestowed on these neighboring streams, calling the present Colorado the Brazos de Dios, and the present Brazos the Colorado or ruddy.

COLORADO, Rio Colorado, or **Colorado River of the West,** a river formed by the junction of the Green and Grand rivers in S. E. Utah, about lat. 38° N., lon. 110° W. Green river rises in the Rocky mountains near Fremont's peak, in the W. part of Wyoming territory, flows S., turns S. E. through the N. E. corner of Utah, entering the N. W. corner of Colorado, then bends S. W. and reënters Utah, and afterward pursues a general S. course to its junction with the Grand. Among its tributaries are the Yampah or Bear, the White, Uintah, and San Rafael. Grand river rises in the Rocky mountains, in Middle park, W. of Denver, Colorado, and has a S. W. course. Its principal tributaries are the South fork or Gunnison, Rio San Miguel, and Dolores. Below the junction the Colorado flows S. W. into Arizona. Near the 36th parallel it makes a bend, and pursues a winding course in a general W. direction to the border of Nevada, whence it flows S., separating Arizona from Nevada and California, and Sonora from Lower California, until it discharges its waters into the gulf of California. The principal tributaries from the east are the San Juan in Utah, and the Colorado Chiquito, or Little Colorado, Bill Williams fork, and Gila, in Arizona. From the west the only noticeable affluents are the Dirty Devil and Escalante in Utah, the Paria, Tapeat's river, and the Kanab, from Arizona, and the Rio Virgen, which enters from Nevada. In many respects the Colorado is remarkable. Above Callville, Nevada, the river, as well as its tributaries, flows through deep cañons, the walls of which in some places rise nearly 7,000

ft. above the surface of the water. Upon the generally treeless plateaus divided by these rivers rise other terraces, with nearly perpendicular walls 1,000 ft. or more in height. Both the loftier and lower plateaus are covered with massive ruins of once populous walled towns and cities, which are supposed to have been occupied by the Toltecs, the predecessors of the Aztecs. The Moqui Indians in N. E. Arizona, near the Colorado Chiquito, are supposed to be descendants of this race. The Green river first enters the Uintah mountains in the extreme N. W. corner of Colorado, at a point called Flaming Gorge, just below which the walls of the cañon are nearly 1,500 ft. high. The stream is swift, the descent being in places 20 ft. to the mile. Rapids and cataracts, some of them of great height, are frequent. Above the junction of the Grand there is generally on the one side or the other a narrow strip of land forming the valley of the river. The extent of these cañons is over 500 m. The largest and most noted of them, the Grand cañon, extends down the river, from the mouth of the Little Colorado, a distance of more than 200 m. The height of the walls varies from 4,000 to 7,000 ft. The channel is from 50 to 300 ft. in width, and the descent of the stream from 5 to 200 ft. to the mile. "The banks of the river," says Major Powell, "are cliffs of solid rock, often vertical for hundreds or thousands of feet; but in places these cliffs or walls of the cañon are broken down in steep slopes, and in other places they are terraced on a grand scale, the glacis often being from a half mile to a mile in width, and the step to a higher terrace several hundred feet. There is no proper flood plain along the river through this cañon, but usually rocks have fallen down from the walls on one or both sides, so as to form a talus, varying from 25 to 300 ft. in height. But in other places there is no talus, the river filling the channel from wall to wall. Numerous streams come down from the high plateaus on either side, each having its own winding cañon, and these have tributary cañons, making the topography adjacent to the river exceedingly intricate." In the valley of the Colorado below the cañons is found a large extent of fertile bottom land, easily cultivated by artificial irrigation. This valley varies in width from 3 to 8 m. The greater part of it is covered with timber, chiefly cottonwood and mezquite. Just below Callville is the Black cañon, about 25 m. long, with walls in places from 1,000 to 1,500 ft. high, which is the only cañon below the Grand cañon. After receiving the Gila, the Colorado takes a sudden turn westward, forcing its way through a chain of rocky hills, 70 ft. high and about 350 yards in length. In this passage it is about 600 ft. wide, but soon expands to 1,200 ft., which it retains. After sweeping round 7 or 8 m., it resumes its S. direction, and pursues a very tortuous course of nearly 180 m. to its mouth. The bottom lands are here from 4 to 5 m. wide, and covered with a thick forest.—The length of the Colorado, from the sources of Green river, is about 2,000 m. It is navigable for steamers to Callville, 612 m.; and it is thought that navigation may be carried to the foot of Grand cañon, 57 m. above. Arnold's point, 35 m. from the mouth, is the head of navigation at low water (winter) for vessels drawing 9 ft. To the head of tide water, 40 m., navigation is difficult and dangerous, from the rapid rise of the tide and the shifting of the channel. Above this point the current, obstructed by small snags and sawyers, runs from 1 to 3 m. an hour (in freshets from 2 to 6 m.) through a narrow channel. The rise of ordinary spring tides is 12 ft. In freshets the river rises at Arnold's point 15 ft. above low water, and in seasons of unusual height it flows back over the California desert, filling up several basins, and what is known as New river, in Lower California. This water remains one or two years, when it is swallowed up by the sands, or evaporated by the hot sun. At the mouth of the river a good harbor was discovered in 1864. It consists in fact of a second mouth of the Colorado, which branches off some 80 m. up, and empties in such a way as to afford secure shelter from the terrible "borers" of the gulf. It is from 50 to 80 yards broad, and with perpendicular banks of hard clay some 25 ft. high at low tide. At high tide the banks overflow a few inches, but the anchorage remains good. About 6 m. up there is an abrupt fall extending across the stream, some 4 or 5 ft. high at low water, but disappearing at high tide. The depth of water in this singular harbor at low tide is from 15 to 25 ft. This harbor is now used almost exclusively by the vessels in the Colorado trade. Their cargoes are here transferred to the small river boats and barges, and they here receive their outward-bound freights. — In 1540 Fernando Alarcon, in a voyage to explore the gulf of California, by order of the viceroy of Spain, discovered the mouth of the Colorado, which he describes as "a very mighty river, which ran with so great a fury of stream, that we could hardly sail against it." He fitted out two boats with which he sailed up the river. Father Kino, about the year 1700, also sailed up to the confluence with the Gila, where he established a mission. Lieut. Ives explored the Colorado below the cañons in a steamer in 1857. The first descent through the cañons was made in 1867 by James White, from a point on Grand river about 30 m. above its junction with the Green. White, Capt. Baker, an old miner and an ex-officer of the confederacy, and Henry Strole were prospecting for gold in the W. portion of Colorado. Having met with ill success, and having lost Capt. Baker during an attack by Indians in a lateral cañon of the Grand, which they had descended for water, White and Strole determined to attempt an escape by the river rather than retrace their steps through a country beset by Indians. They constructed a frail raft of a

few pieces of drift wood, and, having secured their arms and provisions, commenced their downward journey on the night of Aug. 24. Subsequently the raft was generally secured by night and allowed to drift only during the day. On the 28th, while descending a cataract, Strole was drowned, and all the provisions were washed overboard. White continued the journey alone, amid great peril from cataracts, rocks, and whirlpools, hemmed in by the walls of the cañon, and 10 days after reached Callville, having tasted food but twice during that period. Once he obtained a few green pods and leaves from bushes growing along the stream, and the second time he was given some food by Yampais Indians who occupied a low alluvial strip of land along the river, the trail to which from the plateau was known only to themselves. In 1869 a corps fitted out by the United States government, under the command of Prof. J. W. Powell, started in boats from the upper Green river in Wyoming territory, and, after much peril and many hair-breadth escapes, reached Callville, having passed through the whole length of the cañons. In 1871 another expedition under Prof. Powell was fitted out for the exploration of the Colorado valley. The portion of the river embraced in this exploration is about 1,000 m. in length, commencing where the Union Pacific railroad crosses Green river, and extending down the stream to the end of the Grand cañon. E. and S. of the river the survey runs back from 10 to 40 m. from the stream. On Jan. 1, 1873, the exploration had been completed of the region N. and W. of the Colorado, drained by its tributaries, from the Rio Virgen on the south to the Dirty Devil on the north, embracing a territory 300 m. long and 175 m. wide. N. of this a general reconnoissance had also been made of the territory between the Wasatch mountains and San Pete valley on the west and Green river on the east, embracing the valley of the Uintah, the ranges of mountains and extensive plateaus lying S., the valley of Price river, the Wasatch plateau, the valley of the San Rafael, and the plateau and mountains in which this river has its sources. The survey of the region embraced in Prof. Powell's plan is to be completed in 1875, when the entire valley of the Colorado will have been explored, the portion above the Union Pacific railroad and that below the Grand cañon having been already surveyed.

COLORADO, or **Cobu Leubu,** a river of the Argentine Republic, rising in the Andes about lat. 35° S., and flowing S. E. across the pampas through an imperfectly known country to the Atlantic, which it enters in lat. 39° 51′ S., lon. 62° 4′ W.; length about 600 m. By some authorities it is supposed to receive the waters of the Mendoza and the Desaguadero, which drain the great system of lakes in San Luis and Mendoza. It discharges through several mouths, the principal one having two fathoms of water at low tide. It is obstructed seaward by shifting sand banks. The tide rises at its mouth from six to nine feet. It is said to be navigable only about 120 m.

COLOR-BLINDNESS, a curious defect in vision, depending on a want of sensibility in the eye, or perceptive capacity in the brain, in consequence of which certain colors are not distinguished, or all colors are alike invisible as such. It is believed that attention was first called to this defect by the publication by Dr. Dalton, the distinguished chemist, in 1794, of the particulars of his own case. The name given to the affection is that proposed by Dr. George Wilson, from whose work on the subject (Edinburgh, 1855) the following summary is chiefly condensed. It has also been called Daltonism. A cause for the lateness of the discovery of this phenomenon may be found in the fact that while the ignorant would not investigate a disability of the kind under which they might labor, the educated and intelligent would learn to compensate for it by the use of other senses. No mention of color-blindness has been found in ancient or modern writers up to the period named; but the examples of the affection already collected are numerous, and among its subjects were Dugald Stewart and Sismondi, contemporaries of Dalton. The difficulty shows itself in three forms or degrees: 1, in an inability to distinguish nicer shades and hues, such as grays and neutral tints; 2, in inability to distinguish certain primary colors from each other, as red from green, or these from secondary or tertiary hues, as scarlet, purple, &c.; 3, in inability to discern any color as such, the person seeing only white and black, lights and shades. In the first degree, this affection is, among males, rather the rule than the exception. Dr. Wilson found that of 1,154 persons examined by him in Edinburgh, more than one in 18 were in a greater or less degree color-blind; and that of 60 persons in the chemical class of the Edinburgh veterinary college, the majority declined to name any colors beyond red, blue, yellow, green, and brown; while they failed entirely in attempting to arrange nearly related hues of yarns or stuffs, or those of varying shades of the same hue. He found that pink and other pale colors, especially pale yellow and blue and green, were often confounded. The same thing happened with orange and yellow, lilac and bluish gray, &c. In the second degree, in the less marked cases, red and green, or these with olive and brown, fail to be distinguished. And it is apparently singular that colors among the most distinct to a normal eye are in these cases the most easily confounded, red and green being more readily so than yellow and purple; while green is in these respects the most delinquent of all the colors. Dugald Stewart could not distinguish the red fruit of the Siberian crab from the green color of its leaves. Three brothers, Harris, mistook red for green, orange for grass green, yellow for light green. A tailor at Plymouth regarded the solar spectrum as consisting only

of yellow and light blue; while indigo and Prussian blue he pronounced black. Dr. Dalton could not by daylight tell blue from pink; he scarcely saw the red of the spectrum, and considered the remainder of it as showing but two colors. But a failure to perceive the more refrangible rays is most common. Seebach concludes that all eyes, however imperfect otherwise, see yellow; and that the sensations of complementary colors are inseparable, so that if the eye be sensible or insensible to either it will be so to both, the eye that fails to see orange also mistaking blue, &c. In the third degree, however, admitted by other observers, all colors are recognized only as giving certain degrees of light or shade. This form is rare. Dr. Wilson found but one case; and in this some of the colors could be named by gas light or transmitted light, none by reflected daylight.—The color-blind very often do not know their own defect; and in the lower walks of life their lack incapacitates them for certain employments, or may even imperil life. These evils particularly befall weavers, tailors, gardeners, railway attendants, sailors in the steam service, and others dependent on the use of colored articles or the perception of colored signals. The importance of a correct perception of colors, in the present modes of signalling upon railways and shipping, cannot be overestimated. For example, the English admiralty orders require at night a green light on the starboard, a red light on the port side of vessels; and by the color the steersman must know which side of the vessel is toward him, consequently whether it is going to right or left, and whether to starboard or port his helm. Although no case of accident has yet been traced to color-blindness in the attendants, yet such a result is easily conceivable, especially as their powers of vision are not tested; and the most doubtful complementaries, red and green, are much in use as signals. Practical inferences are that the ability in this respect of candidates for the posts of sailors and railway men should always be first carefully tested; but, better still, that form and position of signals should, as far as practicable, be substituted for color, as the former are qualities less liable to be mistaken, and the color-blind generally perceive form even more correctly than other persons.—The cause of color-blindness probably lies somewhere between the eye, as an organ, and the mind; or more correctly, in a want, partial or total, of a certain perceptive faculty, that of color, as an element of active mind. Dalton thought the retina or humors of his eyes must be colored, and probably blue; a nice *post-mortem* dissection of his eyes revealed no abnormal coloration or appearance whatever. Dr. Trinchinetti proposed as a cure the extraction of the crystalline lens; but Wilson gives a case of cataract, in which color-blindness supervened on the extraction of the lens. In one instance, the latter found the difficulty to follow permanently on concussion of the brain; sometimes it was temporary, and dependent on congestion, dyspepsia, or hepatic derangement; most frequently it was congenital. Color-blindness is generally hereditary. Leber, who examined many cases, found it a frequent sympton of atrophy of the optic nerve, and of scotoma (*muscæ volitantes*, &c.). Dr. Argyll Robertson (Edinburgh "Medical Journal," February, 1869) found it accompanying a case of spinal disease. Dr. Chisholm of Charleston, S. C., observed it in a case of inflammation of the optic nerve. It is often, however, unaccompanied with any impairment of vision. It has been observed during pregnancy, and Lawson met with a case which was produced by over use of the eyes in sorting colors. As has already been noticed, the ethereal waves of light in the different colored rays vibrate in different times, the number of vibrations in the middle red ray being about 477,000,000,000,000, while the number in violet light is 699,000,000,000,000 times in a second. There are also waves on either side of these limits which are too slow on the one hand, and too rapid on the other, to be perceived by the human eye, just as some vibrations in the air may be too slow or too rapid to be perceived by the ear. That some persons can perceive a lower tone of red, or the more extreme rays of the violet spectrum, as well as that some can perceive lower or higher notes in music, is a matter of observation, as also the fact that the perception of the depth and tone of various colors varies in different individuals. It is then a matter of no great surprise that in some persons the retina should fail to perceive the difference between the vibrations which take place in some of the colored rays. In the congenital cases, and in some others, the attempt at cure by medicines has been found utterly hopeless; of a cure through education no case is established. The want may be alleviated by carrying about a chromatic scale, named, for purposes of comparison; but little help is thus derived. It is strange that the substitution of artificial for solar light seems as yet to offer decided relief in the largest number of cases; and a draper has been known to keep his shop lighted with gas during the day for this purpose, and with success. Very white light is less useful in these cases; the best being a light yellow by passing through stained glass. Dr. Wilson found that a good test for persons confounding red and green, and who may be unaware of the fact, was obtained by placing before their eyes a red glass; the beholder is at once astonished at the difference which he discovers in looking at the two colors.

COLOR-HEARING. See supplement.

COLORIMETER, an instrument for measuring the depth of color in a liquid by comparison with a standard liquid of the same tint. The comparison is made either by varying the depth of the stratum of liquid under examination till it exhibits the same intensity of color as the normal liquid, and then measuring the

depth of the stratum, or by diluting the stronger-colored liquid with water till equal columns of the two exhibit the same color.

COLOSSÆ, an important ancient city of S. W. Phrygia, on the river Lycus, an affluent of the Mæander. Xenophon speaks of it as being a large and flourishing place at the close of the 5th century B. C. At a still earlier period (481) Xerxes passed through it on his way to Greece. Colossæ was famous for beautifully dyed wool, and carried on an extensive trade in that article. After the time of Cyrus the Younger it seems gradually to have fallen into decay. It was the seat of one of the earliest Christian churches, to which one of St. Paul's epistles is addressed. During the middle ages it was called Chonæ. Khonos, a modern town on its site, is 120 m. S. E. of Smyrna.

COLOSSEUM, Coliseum, or **Colisæum,** an immense amphitheatre in Rome, the largest permanent structure of the kind ever built, standing near the centre of the ancient city, upon the spot once occupied by the reservoir of Nero, about 500 yards S. E. of the Roman forum, and 200 S. W. of the baths of Titus. Its ruins are still sufficiently complete to show the form of almost the entire structure, and are among the best preserved and most magnificent remains in modern Rome. The building was at first called the Flavian amphitheatre, the name Colosseum being first used some centuries later with reference to its immense size. It was begun by Vespasian, built by him as far as the top of the third row of arches, and finished by his son Titus, by whom it was dedicated in A. D. 80, with games, gladiatorial shows, and scenic exhibitions of unprecedented splendor, a great number of gladiators and several thousand wild beasts being killed in contests in the arena. The building, which covers nearly five acres, and in its complete state had accommodation for 80,000 spectators, is in the

The Colosseum.

form of an ellipse; its longer diameter is 615 ft., its shorter 510; the height of its outer wall, where it is still entire, is 164 ft. The arena within is 281 ft. in length and 176 in breadth. The exterior wall of the edifice consists of four stories, of three different orders of architecture; the first (lowest) is Doric, the second Ionic, the third and fourth Corinthian. The material was chiefly travertine for the principal walls, the spaces between being filled in with brick. The part of the Colosseum designed for spectators is in its leading features arranged like that in other ancient structures of the same design (see AMPHITHEATRE); but the fact that in the ruin no traces are to be found indicating that the ranges of seats ever rose higher than at present, *i. e.*, to the bottom of the third story, or half the whole height, has perplexed all antiquaries. It is hardly to be supposed that the whole upper part of the building, erected at immense expense, was added for no object but to increase the exterior height; yet, if the places for spectators never extended to a higher point than would appear from the remains now existing, the upper stories would seem to have been only useful for that purpose. Various theories have been advanced on this subject; one of the most plausible is that the extra stories were in some way rendered necessary by the machinery of the *velarium* (awning or temporary roof) sometimes spread over the whole; another, that narrow galleries ran round the inner circumference of these upper walls; but this must remain a matter of conjecture. What was the position of the dens for the wild beasts used

in the combats of the arena has been another vexed question, as no traces of them are found; it appears probable, however, that they were situated under the *podium*, where they would open directly into the arena.—The best known events in the history of the Colosseum are those connected with the history of the Christian church. Many of the early Christians suffered martyrdom in its arena. St. Ignatius is said to have been the first, he having been given to the lions in this amphitheatre in the earliest days of Christianity. St. Potitus, St. Prisca, St. Martina, and many others, are recorded as having been put to death in the Colosseum in the 2d and 3d centuries, with hundreds of unnamed martyrs, of whom the only records remaining are notes of the number suffering together on the occasion of one festival or another. A cross now stands in the centre of the arena, erected in memory of their martyrdom; and around the edge, close to the wall of the *podium*, are small chapels or stations, marking the stages of the Via Crucis, the devotional exercise of the Roman Catholic church commemorative of Christ's progress to the crucifixion. These devotions are still performed in the Colosseum on Friday of each week. Excepting the record of these martyrdoms, carefully compiled by ecclesiastical historians and undoubtedly largely mixed with tradition, the Colosseum finds singularly little mention in the works of ancient authors. The building is supposed to have remained entire until Rome was invaded by Robert Guiscard, who began its demolition to prevent its being used as a fortress. It served that purpose in the middle ages, however, and was long held as a stronghold by the family of Frangipani, until they were dislodged by their enemies the Annibaldi. In 1312 the muncipality took possession of it, and it was again used for public entertainments, especially for bull fights. In 1387 the canons of the Lateran were allowed to use it for a hospital. After the 14th century it began to be despoiled by the great Roman families, who used its stone to build their palaces. In the time of Sixtus V. it was proposed to turn it into a place of trade, erecting shops under the arcades; but the plan was unsuccessful. Clement XI. endeavored to erect within it a manufactory of saltpetre, but he failed to carry out his design, and was persuaded to finally consecrate it to the memory of the martyrs, thus throwing over it a protection which preserved it from further injury.

COLOSSIANS, Epistle to the, one of the smaller Pauline epistles of the New Testament, addressed to the church of Colossæ. It bears a great similarity to the Epistle to the Ephesians, and is directed against some heretical doctrines which had crept into the Colossian church, and which this epistle represents as endangering the purity of the Christian religion. In the opinion of former exegetical writers these heretical doctrines were the views of Judaistic theosophists, or of some pagan philosophical system; Credner and Thiersch believed a kind of Christian Essenism to be referred to; but the prevailing opinion now is that we find here early traces of Gnosticism. The Pauline origin of the epistle was generally recognized until Mayerhoff (*Der Brief an die Kolosser*, Berlin, 1838) denied its authenticity. He was followed by Schwegler (*Das nachapostolische Zeitalter*, Tübingen, 1845–'6), and by F. C. Baur (*Paulus, der Apostel Jesu Christi*, Stuttgart, 1845). Ewald (*Die Sendschreiben des Apostels Paulus*, Göttingen, 1857) expressed the opinion that the epistle was written by Timothy after receiving from Paul special instructions with regard to the contents. But the great majority of exegetical writers adhere to the tradition of the Pauline origin of the epistle. According to David Schulz (1829), with whom several other modern writers (as Schenkel) agree, the epistle was written during the captivity of Paul at Cæsarea, in 60 or 61; but the almost universal testimony of tradition, according to which it was written by Paul from Rome in 62, is ably defended by Bleek (*Vorlesungen über die Briefe an die Kolosser*, &c., Berlin, 1865) and others.

COLOSSUS (Gr. *κολοσσός*), a statue of gigantic size. Such statues were often erected in ancient times, and many still remain in existence, especially among the ruins of Thebes in Egypt. The most celebrated colossus of ancient or modern time was that at Rhodes. This city had been besieged by Demetrius Poliorcetes, king of Macedon; but, assisted by Ptolemy Soter, king of Egypt, the citizens repulsed their enemies. To express their gratitude to their noble friends, and to their tutelary deity, they erected a brazen statue to Apollo. Chares of Lindus, the pupil of Lysippus, commenced the work; but having expended the whole amount intrusted to him before it was half completed, he committed suicide, and it was finished by Laches. The statue was 105 ft. high, and hollow, with a winding staircase that ascended to the head. After standing 56 years, it was overthrown by an earthquake in 224 B. C., and lay nine centuries on the ground, and then was sold to a Jew by the Saracens, who had captured Rhodes, after the middle of the 7th century. It is said to have required 900 camels to remove the metal, and from this statement it has been calculated that its weight was 720,000 lbs. According to Pliny, Rhodes had 100 colossi of inferior size. The researches of Cesnola in Cyprus have discovered many colossi in that island. Phidias erected several colossi. His Minerva in the Parthenon was 39 ft. high, composed of gold and ivory. Upon the shield was sculptured the battle of the Athenians and Amazons; on the buskins the battle of the centaurs and Lapithæ; on the pedestal, the birth and history of Pandora. He likewise erected for the Eleans a statue of Jupiter 60 ft. high. Lysippus, in the time of Alexander the Great, constructed

at Tarentum a colossal statue, 60 ft. high, which Fabius, on the capture of that city during the second Punic war, was anxious to remove to Rome, but was prevented by its weight. The earliest colossus at Rome was that of Jupiter Capitolinus, in bronze, erected by Spurius Carvilius after his victory over the Samnites; but colossal statues soon became common. Those particularly remarkable were that of Jupiter in bronze upon the capitol; one in bronze of Apollo, at the Palatine library; another in bronze of Augustus, in the *forum Augusti;* a marble statue of Nero, said to have been 120 ft. high, placed in the vestibule of the golden house, afterward supplied with a new head by Vespasian, and converted into an Apollo; and a gilt bronze statue of Domitian as the deity of the sun, in the forum.—There are two statues which belong to recent art deserving the name of colossal. One is the statue of San Carlo Borromeo, at Arona, near the S. extremity of Lago Maggiore, erected in 1697. It stands on a hill. Its pedestal is 40 ft. in height, and the statue itself 66 ft. The head, hands, and feet are cast in bronze; the rest of the figure is formed by laying sheets of hammered copper upon a pillar of masonry. The statue may be entered and ascended; there is sufficient room for three persons inside of the head, and for one person inside of the nose. The other is that of Bavaria, at Munich, in bronze, 61½ ft. high, with a pedestal of 28½ ft.; it was designed by Schwanthaler, and completed in 1850.

COLOT, Laurent, a French surgeon, born at Tresnel, near Troyes, lived in the middle of the 16th century. He was instructed by Octavien Deville, a pupil of Marianus Sanctus, in the art of extracting stone from the bladder. He kept the process secret, and upon the death of Deville was appointed by Henry II. lithotomist at the Hôtel-Dieu. The secret was transmitted to his grandson PHILIPPE (born in 1593, died in 1656), who had an extensive practice in lithotomy. He taught the process to Restitut Girault and Séverin Pineau. FRANÇOIS COLOT, who died June 25, 1706, was instructed in the art by the son of Girault, and wrote a treatise upon the subject (Paris, 1727).

COLQUHOUN, Patrick, a British author, born at Dumbarton, Scotland, March 14, 1745, died in London, April 25, 1820. In early life he went to America, but returned to Scotland in 1756. On the outbreak of the American war he contributed to a fund for raising a regiment against the colonists. In 1782 he was elected chief magistrate of Glasgow. In 1789 he removed to London, and in 1792 was appointed a police magistrate. He published "A Treatise on the Police of the Metropolis" (London, 1796), "A Treatise on the Police of the River Thames," "A New System of Education for the Laboring People," "A Treatise on Indigence," and "On the Population, Wealth, Power, and Resources of the British Empire" (London, 1814). The first and last named works were translated into German.

COLQUITT, a S. W. county of Georgia, bounded E. by the Withlacoochee river, and intersected by the Ocopilco and branches of the Ocklockonee; area, 600 sq. m.; pop. in 1870, 1,654, of whom 137 were colored. The surface is level. The chief productions in 1870 were 24,132 bushels of Indian corn, 11,834 of sweet potatoes, 24,468 lbs. of wool, and 327 bales of cotton. There were 183 horses, 1,804 milch cows, 3,852 other cattle, 9,061 sheep, and 6,348 swine. Capital, Moultrie.

COLT, Samuel, an American inventor, born in Hartford, Conn., July 19, 1814, died there, Jan. 10, 1862. His restless spirit led him even when a child to prefer the work room to the school room, and he entered at the age of 10 a factory belonging to his father, who was a manufacturer of woollen and silk goods. In his 14th year he was sent to school in Amherst, Mass., but ran away and shipped as a boy before the mast for an East India voyage. While at sea he made a model in wood of a revolving pistol, which was the germ of the celebrated weapon bearing his name. This model is still in existence. After his return from Calcutta he familiarized himself with the principles of chemistry under the tuition of the manager of the dyeing and bleaching department in his father's factory at Ware, Mass.; and having become a dexterous manipulator, he travelled through the United States and Canada, giving lectures on chemistry in almost every city. During the two years spent in this way he acquired means sufficient to prosecute his invention. In 1835 he visited England and France and secured patents for revolving firearms, and on his return took out patents in this country. On a subsequent visit to Europe he discovered that there were in the tower of London ancient guns having a rotary chambered breech; and in order to free himself from the imputation of claiming an invention which had previously been made, he read before the institution of civil engineers in England (of which he was the only American associate), in 1851, an elaborate paper on the subject, in which he described the various early revolving firearms, and demonstrated the principles on which his own were constructed. In 1835, with the aid of New York capitalists, he established a company for the manufacture of his arms in Paterson, N. J., with a capital of $300,000. A large amount was expended in machinery and in experiments, but the company did not succeed in securing the general adoption of the weapon, though a few were used with success in the war with the Seminoles in 1837. In 1842 the patent arms company, as it was named, became insolvent, and for five years no revolvers were made. In 1847, during the Mexican war, Gen. Taylor, who had learned the value of the weapon in Florida, sent for a supply, but none were to be found. The government ordered 1,000 to be made. Mr. Colt advertised in vain for one to serve as a model, and was compelled to make a new model, in which he incorpora-

ted improvements suggested by the experience of officers. He manufactured these pistols in an armory at Whitneyville, near New Haven, Conn.; but other orders following, he procured more commodious workshops in Hartford, and began business on his own account. In 1852, finding that his means for manufacturing were insufficient to supply the great demand which had arisen for revolvers, in consequence of the emigration to California and Australia, he purchased 250 acres of low meadow land in the S. part of the city of Hartford, surrounded it with an immense dike to prevent its annual overflow by the river, and began the erection within it of the armory, which has since become one of the most extensive in the world. The original building, which is of Portland freestone, consists of two parallel structures, 500 ft. in length and 60 and 40 ft. respectively in breadth, connected by a central one 250 ft. by 50, the whole being in the form of the letter H. In 1861 a second building, similar in most respects, was erected; and in connection with these are offices, warerooms, and other outbuildings. Within the dike were subsequently built numerous dwellings for workmen and other structures, the whole involving an expenditure of more than $2,500,000. This armory is capable of manufacturing over 1,000 firearms a day. A part of the establishment is devoted to the construction of machinery for making the revolving weapons, and from it were supplied the machines used for that purpose in the armory of the British government at Enfield and in that of the Russian government at Tula. All the accessories of the weapons, balls, cartridges, bullet moulds, powder flasks, lubricators, &c., are made at the armory, from models of Mr. Colt's or developed from his ideas by his workmen. Besides the revolver, Mr. Colt invented a submarine battery for the defence of harbors, which has met with the approval of distinguished naval officers. He devised also a method of insulating submarine telegraphic cables, and in 1843 laid a cable from Coney and Fire islands to the city of New York, which was operated with success. He received from almost all the European governments, and from several Asiatic sovereigns, decorations, medals, diplomas, and other tokens of their appreciation of his merits.

COLTON, Calvin, an American clergyman and political writer, born at Longmeadow, Mass., in 1789, died in Savannah, Ga., March 13, 1857. He graduated at Yale college in 1812, studied theology at Andover, and was ordained and settled in the Presbyterian church at Batavia, N. Y., in 1815. On account of the failure of his voice, he relinquished preaching in 1826, began writing for periodicals, and went to England in 1831 as a newspaper correspondent. On his return in 1835 he published a work entitled "Four Years in Great Britain." About this time he became a member of the Episcopal church, took orders, and wrote a book entitled "Thoughts on the Religious State of the Country, and Reasons for preferring Episcopacy." But soon returning to his former occupation, he distinguished himself as a writer of political pamphlets and fugitive pieces, in which he defended the views of the whig party. Those which had the widest circulation were a series called the "Junius Papers," published originally in 1840, republished in 1844 with additions. He edited a newspaper in Washington from 1842 to 1844; in 1846 published the "Life and Times of Henry Clay;" in 1848, "Public Economy for the United States," containing an elaborate argument in favor of a protective policy; and in 1853, "The Genius and Mission of the Protestant Episcopal Church in the United States." In 1852 he was appointed professor of public economy in Trinity college, Hartford. He also published "Private Correspondence of Henry Clay" (1855), "Last Seven Years of the Life of Henry Clay" (1856), and "Speeches of Henry Clay" (2 vols., 1857).

COLTON, Caleb Charles, an English writer, born in 1780, died by his own hand at Fontainebleau, France, April 28, 1832. He graduated at Cambridge in 1801, was chosen fellow of King's college, and in 1818 obtained the vicarage of Kew and Petersham. But he contracted habits of life which destroyed all the hopes formed from his brilliant abilities. He became a gambler, and was involved in so much embarrassment that he was obliged to flee to America. He afterward went to Paris, where he acted for a time as correspondent of the London "Morning Chronicle." He is said to have won in Paris £25,000 at play within two years; but he committed suicide through apprehension of a surgical operation that had become necessary. His principal works are: "Hypocrisy, a Satirical Poem" (1812); "Napoleon, a Poem" (1812); "Lines on the Conflagration of Moscow" (1816); and "Lacon, or Many Things in Few Words" (1820). The last named is a collection of ethical aphorisms, and is the most popular of his works.

COLTON, Walter, an American clergyman and writer, born in Rutland, Vt., May 9, 1797, died in Philadelphia, Jan. 22, 1851. He graduated at Yale college in 1822, at Andover theological seminary in 1825, and became professor of moral philosophy and belles-lettres in the scientific and military academy at Middletown, Conn. In 1830 he edited a journal in Washington, and in the following year was appointed chaplain in the navy, and ordered to the Mediterranean. While on that station he gathered the materials for his "Ship and Shore in Madeira, Lisbon, and the Mediterranean" (New York, 1835), "Visit to Athens and Constantinople" (1836), "Land and Lee in the Bosporus and Ægean" (1851), and "Notes on France and Italy" (1851). In 1835 he was assigned to the naval station at Charlestown, Mass.; in 1837 he edited the "Colonization Herald," and in 1838 was assigned to the chaplaincy of the naval station at Philadelphia. In 1845 he was ordered to the Pacific coast,

and on July 28, 1846, was appointed alcalde of Monterey in California by the American military authorities. Having discharged the duties of this office for nearly two months under a military commission, he was elected by the citizens of Monterey as alcalde or chief judge, with a jurisdiction extending over 300 m. of territory. He established the first newspaper and built the first school house in California. The first public announcement of the discovery of gold in California was made by him in a letter to the Philadelphia "North American," in May, 1848. He returned to Philadelphia in 1849. His "Deck and Port" and "Three Years in California" were published in 1850; and a volume of "Literary Remains," with a memoir by Henry T. Cheever, in 1851.

COLTSFOOT (*tussilago farfara*), an herb growing wild in Europe and North America; found in this country in the northern and middle states. Though the whole plant is used, its virtue is principally in the leaves. These are

Coltsfoot (Tussilago farfara).

gathered and dried, and used generally in the form of a decoction. Coltsfoot is employed in pulmonary complaints, as a demulcent, often in the form of cough candy. It is said to have been smoked by the ancients in affections of the lungs.

COLUBER, the principal genus of a family of ophidian reptiles, characterized by an elongated head, distinct from the neck, and covered above with smooth polygonal plates; the snout rather rounded; the eyes large, and the pupil round; the body long, cylindrical, and tapering, covered above with rhomboidal scales, generally smooth, but sometimes carinated. The tail has always double plates on the under surface; the plates of the abdomen are transverse; the jaws furnished with numerous sharp teeth, directed backward, without poisonous fangs. Some species are oviparous, others ovoviviparous. In the old Linnæan genus *coluber* were included all ophidians having double plates on the under surface of the tail; this embraced many venomous serpents; the genus has since been restricted by Boie, Schlegel, and others, so that it now forms a very natural one, recognized rather by its general than by any isolated characters. Its numerous species are found in most parts of the globe where any ophidians can exist; they are generally terrestrial, rarely entering the water unless from necessity; most of them climb trees easily, where they lie in wait for their prey; some are found in marshy districts, some in thick woods, some in open sandy plains, and the locality impresses various habits of life upon them; they generally pursue small mammals, birds, and reptiles. They attain a considerable size, sometimes a length of 8 ft. The abdominal plates and the ribs are exceedingly numerous, sometimes as many as 300. The sides of the snout are rarely concave, and the plates over the eye are not very prominent, giving to their physiognomy a gentle expression, which is confirmed by the disposition of many of the species living in the vicinity of man. The colors are rarely brilliant, brown shading into black or green being the prevailing tints; some are striped or spotted, but all undergo considerable changes in their progress to maturity. The genus has since been subdivided into many. Among the best known species is the one dedicated to Æsculapius (*C. Æsculapii*, Lacép.), emblem of the sagacity and health-bestowing qualities of the great physician; and, in this country, the black snake (*bascanion constrictor*, B. and G.), the corn snake (*scotophis guttatus*, B. and G.), the chicken snake (*ophibolus eximius*, B. and G.), the indigo snake (*Georgia Couperi*, B. and G.), the green snake (*chlorosoma vernalis*, B. and G.), and the striped snake (*entænia sirtalis*, B. and G.).

COLUGO. See Flying Lemur.

COLUMBA, called by his countrymen Columb-Kille or Cille ("dove of the cell"), a saint of the Roman Catholic church, styled also the apostle of Caledonia, born at Gartan, Donegal, Ireland, in 521, died in Iona, June 9, 597. His father was of the royal race of Niall or O'Donnell, his mother a princess of the reigning family of Leinster. Educated from boyhood by the priest who had baptized him, he passed into the great monastic school of Clonard, under Finnian, styled *magister sanctorum*, who ordained him deacon, and finished his course in the monastery of Maghbile, Down, under another Finnian or Finbar, afterward bishop of Lucca in Italy. His own wealth and powerful connections enabled him to found in Ireland 37 monasteries before his 25th year. He resided at Derry, superintending the other establishments, and fostering in all the love of rural labor, the culture of sacred and profane letters, and the work of translating the Old and New Testaments. A copy which he had furtively made of a rare manuscript of the psalter involved him in a suit with his old master Finnian, which was carried before the king at Tara, who decided against Columba; and soon after, a young prince of Connaught who had

fled to his monastery for asylum having been taken thence by the king's officers and executed, Columba vowed revenge. He hastened into his native province of Tyrconnell, roused all his kinsfolk to arms, and led them against the king, who was defeated at Cool-Drewny. Excommunicated in a synod for this bloodshed, Columba wandered from monastery to monastery, until his confessor as an expiation of his guilt commanded him to leave Ireland for ever. With 12 companion monks he landed on Iona (then called I or Hy, afterward named from him I-Columb-Kill or Icolmkill), where they built cells and devoted themselves to the bodily and spiritual wants of the inhabitants of this and the neighboring isles and the mainland. Iona being in the territory of an Irish colony of Dalriadians, their prince Connal, a kinsman of Columba, bestowed the island on him in 563. His biographer and contemporary Adamnan describes the moral transformation which took place in him. Subdued by remorse for the blood he had caused to be shed, he sought out guilt and suffering that he might purge away the one and alleviate the other. His reputation grew with his community, and the churches and monasteries which they founded on every side. The Dalriadian colony was renovated in 574. Aidan, Connal's successor, sought Columba on his island to confess his sins, and was there blessed and crowned king by the abbot, the first instance of such a ceremony in the history of the West, and the stone which served Aidan for a seat is now in Westminster abbey. From the territory of the Irish-Scots, Columba and his monks had pushed their missionary excursions into the adjoining districts inhabited by the heathen Picts. The opposition of their king was overcome by a miracle; while miracles of patience and devotion overcame the long resistance of the druids, until all Scotland was Christian, and the monastery of Deir (or "Tears") arose on the remotest shore of Buchan, where it flourished 1,000 years. Ancient traditions attribute to Columba the foundation of 300 monasteries or churches. Modern learning has discovered and registered the existence of 90 churches whose origin goes back to him. King Aidan was still held tributary to Ireland; and at his urgent solicitation and that of the Irish communities which had never ceased to regard Columba as their superior, he consented to visit Ireland. A parliament was held in Drumkeath, the king of Ireland and Aidan presiding; princes, nobles, bishops, and abbots discussed for a whole year the interests of church and state. The tribute was remitted to the Dalriadian prince, and his thorough independence acknowledged; the institution of the bards was saved from outlawry, old feuds were healed, a solid basis for future concord was established, and salutary laws were enacted. Columba maintained exact discipline in all his houses. The time not given to missionary labors, prayer, and chanting the divine office, was devoted to manual and intellectual labor. Agriculture was a prime necessity for the monks, and they taught it to the people. Out of doors they labored in the fields, built or repaired churches and monasteries, and constructed wicker boats covered with hides, in which the missionaries ventured to the Faroe isles and to Iceland. Indoors they transcribed the classics, and copied and illuminated the Bible. In all these duties Columba was foremost to the very last; his cell in Iona remaining until his 76th year what it had been at first, made of willow rods and hay, with the bare ground for a bed and a stone for pillow. He died suddenly, having before predicted the hour, while celebrating the midnight office. His life and the fragments of his poems are in Montalembert's "Monks of the West."

COLUMBANUS, a saint of the Roman Catholic church, born in Leinster, Ireland, in 543, died at Bobbio, Italy, Nov. 21, 615. Educated with great care from childhood, he fled from his native place to avoid the dangers to which his personal beauty exposed him, became a monk in the great monastic school of Bangor, and finally in 575 with 12 companions passed over into Brittany, and thence into Gaul. After sojourning for a time in various provinces, where his preaching, charity, and the pure life led by himself and his companions did much to revive religion, he was invited by King Gontran to fix his abode in Burgundy. He chose the ancient Roman castle of Annegray, near Faucogney, in the present department of Haute-Saône. It was in a forest, where after great hardships a monastery was built, the ground cleared and cultivated, and a large community sprung up. Soon their increasing number forced him to beg another residence from the royal favor, and he chose in 590 Luxeuil, the site of another Roman castle, at the foot of the Vosges, and on the confines of Austrasia and Burgundy, and another at Fontaines. Noblemen flocked to Columbanus in such numbers that he was able to establish the *laus perennis*, or perpetual praise, successive choirs of monks singing unceasingly night and day the praise of God. At length a double storm burst upon him: from the bishops, who desired him and his monks to abandon their manner of celebrating Easter; and from Queen Brunehaut and her grandson Thierry, whom Columbanus reproved openly, the king for his licentious life, and the queen for pandering to the king's vices in order to rule in his stead. Banished from Burgundy with all his Irish monks, Columbanus embarked for Ireland, but was cast by a tempest on the shores of Brittany. Thence he proceeded to Laon, where the king of Neustria, Clotaire II., held his court; he reproved him and his mother Fredegonda for their disorders, but was favored and encouraged by both. Having made up his mind to pass over into Italy with his companions, he set out from Laon to Metz, the capital of Theodebert, king of Austrasia. On his way through Cham-

pagne and Brie clergy, nobility, and people flocked around him, his journey to Metz becoming one unbroken series of preachings, conversions, and foundations. He resolved on his way to Italy to convert the Rhine provinces of Austrasia. Embarking below Mentz, he ascended the river, landing and preaching on his way, and finally established himself at Bregenz, on the lake of Constance. The Alemanni and Suevi, who held all eastern Helvetia, were worshippers of Wodin, violent and cruel in their disposition. A monastery was built, and for three years Columbanus labored to make the idolaters give up their gods. At length his protector Theodebert fell into the hands of Brunehaut, who put him to death, and compelled Columbanus to fly. His disciple Gall remained behind to found the great monastic school which bears his name. Columbanus, crossing by the St. Gothard pass, arrived in Lombardy, where he immediately commenced preaching against the Arian heresy. King Agilulf bestowed upon him the territory of Bobbio on the banks of the Trebbia, where he set about erecting a church and monastery. Clotaire II., having vanquished Thierry and Brunehaut, sent a deputation to Bobbio pressing Columbanus to return to Gaul, but in vain. Wishing to withdraw from all human intercourse some time before his death, Columbanus hid himself in a cavern in the Apennines, returning to the monastery only on Sundays and holidays. The excessive bodily punishment imposed on offenders by his rule, with other imperfections, soon caused it to be superseded in all his monasteries by the rule of St. Benedict.—His *Regula Cœnobitalis cum Pœnitentiali* is contained in the *Codex Regularum*, with the notes of the Benedictine Hugues Menard (Paris, 1638). The collection of his works was published by Sirin, with the notes of Fleming (fol., Louvain 1667); also a Latin poem in vol. ii. of Sirmond's *Œuvres diverses*. A life of St. Columbanus and his disciples Attalus and Bertulfus was written in Latin hexameters in the 10th century by Flodoart, canon of Rheims. See also A. Gianelli, *Vita di S. Colombano* (Turin, 1844); and Montalembert's "Monks of the West."

COLUMBIA, the name of seven counties in the United States. **I.** An E. S. E. county of New York, bounded E. by Massachusetts, and W. by the Hudson river; area, 620 sq. m.; pop. in 1870, 47,044. In the E. part the surface is hilly, but in the W. and central portions it is generally level. The soil is fertile and highly cultivated. Iron, lead, limestone, slate, and marble are obtained in various places, and at New Lebanon are warm springs which are much resorted to. It is traversed by the Hudson River, the Harlem, the Boston and Albany, and the Hudson and Boston railroads. The chief productions in 1870 were 3,932 bushels of wheat, 426,408 of rye, 336,281 of Indian corn, 942,307 of oats, 108,971 of buckwheat, 678,480 of potatoes, 112,878 tons of hay, 1,227,274 lbs. of butter, 233,196 of wool, and 58,193 of hops. There were 9,101 horses, 14,030 milch cows, 11,704 other cattle, 53,798 sheep, and 8,865 swine; 13 manufactories of cotton goods, 2 of drugs and chemicals, 7 of hosiery, 3 of pig iron, 7 of iron castings, 20 of paper, 2 of woollen goods, 3 breweries, 32 flour mills, 44 manufactories of carriages and wagons, 9 of agricultural implements, 3 of bricks, 10 of machinery, 19 of saddlery and harness, 17 of tin, copper, and sheet-iron ware, 8 of cigars, and 6 saw mills. Capital, Hudson. **II.** An E. county of Pennsylvania, intersected by the N. branch of the Susquehanna, and drained by Catawissa and Fishing creeks; area, 375 sq. m.; pop. in 1870, 28,766. Knob mountain, Catawissa mountain, and the Muncy hills, which traverse the county, are branches of the Alleghany range, and are wholly unproductive. The valleys lying between them are very fertile, and some of the uplands are also fit for cultivation. Limestone and iron ore are found in great abundance. The North Branch canal, and the Catawissa and the Lackawanna and Bloomsburg railroads traverse the county. The chief productions in 1870 were 240,759 bushels of wheat, 50,616 of rye, 589,472 of Indian corn, 406,031 of oats, 82,676 of buckwheat, 182,124 of potatoes, 22,132 tons of hay, 468,398 lbs. of butter, and 22,337 of wool. There were 4,718 horses, 5,615 milch cows, 4,718 other cattle, 6,823 sheep, and 11,911 swine; 4 flour mills, 3 planing mills, 2 manufactories of machinery, 1 of cars, 2 of pig iron, 8 of iron castings, 19 of carriages and wagons, 9 of lime, 4 of woollen goods, 7 saw mills, and 12 tanneries. Capital, Bloomsburg. **III.** An E. county of Georgia, separated from South Carolina by the Savannah river, bounded N. W. by Little river, and traversed by the Georgia railroad; area, 500 sq. m.; pop. in 1870, 13,529, of whom 9,449 were colored. It has an uneven surface, and a soil once fertile but impaired by improper tillage. A gold mine near Little river has been worked. The chief productions in 1870 were 8,699 bushels of wheat, 121,160 of Indian corn, 11,864 of oats, 15,092 of sweet potatoes, 46,311 lbs. of butter, and 7,434 bales of cotton. There were 910 horses, 1,219 mules and asses, 2,058 milch cows, 3,858 other cattle, and 7,997 swine. Capital, Appling. **IV.** A N. E. county of Florida, bordering on Georgia, bounded S. by the Santa Fé and N. W. by the Suwannee river; area, 864 sq. m.; pop. in 1870, 7,335, of whom 3,228 were colored. The surface is level, and the soil light and sandy. Pine forests cover a considerable part of the county. The Jacksonville, Pensacola, and Mobile railroad passes through it. The chief productions in 1870 were 103,317 bushels of Indian corn, 24,798 of oats, 32,316 of sweet potatoes, 15,526 gallons of molasses, and 1,264 bales of cotton. There were 733 horses, 3,562 milch cows, 7,168 other cattle, 1,654 sheep, and 8,957 swine. Capital, Lake City. **V.** A S. W. county of Arkansas, bordering on Louisiana, watered by

Bayou Dorcheat; area, about 950 sq. m.; pop. in 1870, 11,397, of whom 3,718 were colored. In 1871 a portion was taken to form Nevada co. The surface is level, and the soil fertile. The chief productions in 1870 were 3,149 bushels of wheat, 245,388 of Indian corn, 48,024 of sweet potatoes, and 5,565 bales of cotton. There were 1,042 horses, 944 mules and asses, 2,217 milch cows, 3,889 other cattle, 5,472 sheep, and 13,652 swine. Capital, Magnolia. **VI.** A S. county of Wisconsin, intersected by the Wisconsin and Neenah rivers; area, 751 sq m.; pop. in 1870, 28,802. The surface is rolling or hilly, and the soil rich. The Wisconsin is navigable by steamboats to Winnebago Portage, whence a canal connects it with the Neenah, 1½ m. distant. The Milwaukee and St. Paul railroad crosses the county. The chief productions in 1870 were 1,517,332 bushels of wheat, 40,844 of rye, 528,541 of Indian corn, 678,907 of oats, 51,745 of barley, 202,068 of potatoes, 44,184 tons of hay, 706,516 lbs. of butter, 168,255 of wool, and 230,762 of hops. There were 9,758 horses, 9,659 milch cows, 10,628 other cattle, 40,413 sheep, and 11,743 swine; 3 manufactories of boots and shoes, 13 of carriages and wagons, 2 of bricks, 8 of saddlery and harness, 4 flour mills, 6 breweries, 2 planing mills, 2 saw mills, and 2 leather-currying establishments. Capital, Portage City. **VII.** A N. W. county of Oregon, bounded N. and E. by the Columbia river, separating it from Washington territory, and watered by the Klaskanine; area, 470 sq. m.; pop. in 1870, 863. The W. border is mountainous. Coal and iron are found; the soil is good. The chief productions in 1870 were 1,619 bushels of wheat, 1,169 of Indian corn, 2,260 of oats, 10,337 of potatoes, and 1,850 tons of hay. There were 307 horses, 724 milch cows, 1,303 other cattle, 1,602 sheep, and 1,206 swine. Capital, St. Helens.

COLUMBIA, a city of Lancaster co., Penn., situated on the Susquehanna river, at the terminus of the Philadelphia and Columbia railroad, and of the eastern division of the state canal; pop. in 1870, 6,461. The Columbia branch railroad connects it with Harrisburg, and another with York and Baltimore. It is the principal depot of the lumber which is rafted down the Susquehanna. There are two weekly newspapers and several churches.

COLUMBIA, a city, capital of South Carolina, and seat of justice of Richland county, situated on the E. bank of the Congaree, just below the falls, and at the confluence of the Broad and Saluda rivers, 100 m. N. W. of Charleston; pop. in 1860, 8,052; in 1870, 9,288, of whom 5,295 were colored. The Congaree is navigable to this point, and there is ample communication with the surrounding country by means of the South Carolina, the Greenville and Columbia, the Charlotte, Columbia, and Augusta, and the Wilmington, Columbia, and Augusta railroads. There is an iron bridge over the Congaree, immediately opposite the city, connecting the counties of Richland and Lexington, recently rebuilt at a cost of $40,000; while the approach on the north and west is aided by the Broad river bridge, 1,054 ft. long. Columbia occupies a plain some 200 ft. above the bed of the river, and before the civil war was one of the handsomest places in the south; it was laid out in regular squares, well built, with streets 100 ft. wide, and covered an extent each way of more than 2 m. The view from Arsenal hill is very beautiful. Sydney park contains about 25 acres of ground handsomely laid out in plots, and adorned with trees and shrubbery. The streets are abundantly shaded, and there are many splendid drives in the vicinity. The fair grounds of the South Carolina agricultural and mechanical society, in the N. W. suburbs, are well supplied with fountains and fish ponds, and contain about 30 acres. A race course is attached to them, and large fields for the exhibition of agricultural implements. The principal building is 175 ft. long and 135 deep, with an amphitheatre in front capable of seating 3,000 persons. The new state house, of granite, occupies an eminence in the centre of the city. Though unfinished, it has been covered with a temporary roof, and is now occupied. It has cost upward of $3,000,000, and about $1,000,000 will be required to complete it. The executive mansion has grounds laid out in walks, gardens, and drives, and commands a full view of the Congaree valley. The new city hall, in process of construction, will be of brick, three stories high, with a Mansard roof, and a tower at each end; besides the city offices, it will contain an opera house capable of seating 1,500 persons. The United States court house and post office, also in process of construction, will be of granite, three stories high, with a Mansard roof, and a tower. The market house, near the centre of the city, is a one-story brick building, about 150 ft. long, well ventilated and conveniently arranged. The gas works occupy an acre of ground, and consume annually about 800 barrels of rosin and 500 cords of wood. The gas produced gives a steady and brilliant light. The water power is extensive. Canals were early constructed around the falls, to improve the navigation of the river, which were sold by the state in 1868 to Senator Sprague of Rhode Island. The principal manufacturing establishments are 4 iron works, which produce steam engines, machinery, cotton presses, iron railings and building fronts, bells, and iron and brass castings; an oil factory, producing and refining about 3,000 gallons of cotton-seed oil per week; 2 manufactories of sashes, doors, and blinds; 1 of brooms, 1 of blank books, and a brewery. The car shops of the Charlotte, Columbia, and Augusta railroad occupy four acres of ground, and furnish locomotives, cars, and machinery for the use of the road. In the vicinity of Columbia are forests of yellow pine, oak, walnut, maple, poplar, &c., furnishing material for 15 or 20

saw mills, which produce about 5,000 ft. of lumber a day. The high bluffs of the river supply material for good bricks, and two companies are engaged in the manufacture. Excellent granite exists within the city limits, and is used in the construction of the public buildings. There are three national banks, with a capital of $500,000; a bank and trust company, capital $200,000; and two savings banks, with $644,000 capital. The South Carolina penitentiary, begun in 1867, occupies a plot of 20 acres, at the junction of the Broad and Saluda rivers, within the city limits. It is to be five stories high, with two wings, each containing 250 cells. Each cell is 5 ft. wide, 8 ft. long, and 7 ft. high. The number of prisoners, Oct. 31, 1872, was 224, of whom 10 were females; 90 per cent. were colored. They are employed in the garden, carpenter, blacksmith, and shoe shops, marble works, weaving rooms, and broom factory attached to the institution, and in quarrying the granite for the building, as well as in its erection. The lunatic asylum, situated in the N. E. part of the city, occupies two principal buildings. That for the use of female patients is four stories high, and consists of two wings, with a centre building rising above them, crowned by a cupola. It can accommodate more than 100 patients. The building occupied by the men is about 300 yards from the other, and has capacity for 120 patients. An additional wing 100 ft. long, 40 ft. wide, and 4 stories high, is in process of construction. There are also smaller buildings for the colored patients. The asylum in 1871 contained 285 inmates, of whom 90 were white males, 45 colored males, 115 white females, and 35 colored females. It is a well appointed institution, supported principally by the state. The grounds, 4 acres in extent, are surrounded by an enclosure, and beautified with gardens, hothouses, and walks. The university of South Carolina, founded in 1804, has an observatory connected with it. The grounds are about 12 acres in extent, and the buildings are substantially constructed of brick. In 1871 it had 14 instructors, 70 students, and a library of 27,000 volumes. The Presbyterian theological seminary, founded in 1831, had 7 professors, 41 students, an endowment of $145,715, and a library of 18,340 volumes; the Lutheran theological seminary, founded in 1859, had 2 professors, an endowment of $29,000, and a library of 4,000 volumes. The Columbia male academy, founded in 1785, is in a flourishing condition. The Ursuline convent at Valle Crucis, 2 m. from Columbia, has 20 inmates, who conduct a female seminary, and also have under their charge a day school in the city. The public school system is in its infancy, and is hampered by lack of funds; but in 1871 there were 10 free schools, with 32 teachers and 1,029 pupils. The state library contains about 3,000 volumes. There are 2 daily, 1 tri-weekly, and 7 weekly newspapers, and a monthly and a quarterly periodical. There are 10 or 15 churches, several of which are for colored people. The denominations represented are the Baptist, Episcopal, Lutheran, Methodist, Presbyterian, and Roman Catholic.—Columbia became the capital of the state in 1790, under an act of the legislature of March 22, 1786, which provided for the founding of the city. Toward the close of the civil war it was entered by the forces under Gen. Sherman, Feb. 17, 1865. Shortly before a large amount of cotton had been taken from the warehouses and piled in the streets, preparatory to removing it outside the city and burning it, to prevent its falling into the hands of the Unionists. This not having been effected, however, on the evacuation of the city by the confederate troops under Gen. Wade Hampton, the cotton was set on fire as it lay, whether by accident or design is unknown. Under the influence of a high wind, the flames spread rapidly, and 84 of the 124 blocks of the city, containing over 500 buildings and embracing the entire business quarter, were burned. The old state house, containing the legislative library of 25,000 volumes, five churches, the Ursuline convent, and the railroad depots were consumed. The city has been rapidly rebuilt, and is increasing in population.

COLUMBIA, the capital of Maury co., Tennessee, on the left bank of Duck river, 38 m. S. by W. of Nashville; pop. in 1870, 2,550, of whom 1,108 were colored. The surrounding country is fertile and productive. It is the seat of Jackson college, a female athenæum, female institute, and conference college. A weekly newspaper is published here. There are two banks, with $200,000 capital. Columbia was the residence of President Polk previous to his election. It was at one time the capital of the state. The Nashville and Decatur railroad passes through it.

COLUMBIA, a village, capital of Boone co., Missouri, 115 m. W. N. W. of St. Louis; pop. in 1870, 2,236, of whom 798 were colored. It is situated in a populous and fertile region, and is the seat of the state university. The university building is a large and elegant structure, erected at the expense of the citizens of the county. In 1871 it had 12 instructors, 217 students, of whom 40 were females and 118 were in the preparatory department, and a library of 5,000 volumes. There are two weekly newspapers. A branch of the North Missouri railroad terminates here.

COLUMBIA, British. See British Columbia.

COLUMBIA, District of. See District of Columbia.

COLUMBIA COLLEGE, a seat of learning in the city of New York, originally called King's college. The institution comprises an academic department, law school, medical school, and school of mines. The government of the college proper is vested in 24 trustees. Besides the president, there are 9 professors and 2 tutors. The professorships are: 1, Greek language and literature; 2, German language and

literature; 3, chemistry; 4, mathematics; 5, mathematics and astronomy; 6, philosophy and English literature; 7, mechanics and physics; 8, Latin language and literature; 9, evidences of natural and revealed religion. Each student is required to devote fifteen hours a week to scholastic exercises. During the senior year eight hours a week are assigned to required and seven hours to elective studies. The elective studies are Greek, Latin, physics, calculus, psychology, technology, and organic chemistry; two hours a week are allotted to each of the four first named and three hours to each of the others. The course of study is four years, at the end of which period the degree of bachelor of arts is conferred upon those students who have passed successful examinations. The academic year, which is divided into two terms, begins on the first Monday in October, and closes with commencement day on the last Wednesday in June; there being a vacation of two weeks about Christmas. There are two public examinations annually of all the classes, one in February, and the other at the close of the academic year. Private examinations are held monthly in all the classes, and there is an examination for honors at the end of each year, open to members of the senior class. The annual tuition fee is $100; by a vote of the trustees this charge may be remitted to indigent students. In 1873 the number of students thus receiving instruction free was 24. Prizes amounting to $450 are annually awarded upon examination for proficiency in Greek; in German, $100; in studies relating to theology, $50; and "to the most faithful and deserving student of the graduating class," $50. By means of free scholarships established by the college, certain societies and corporations, including each religious denomination in the city of New York, may send students to be educated free of charge. By a recent resolution of the board of trustees, twelve scholarships have been established of the annual value of $100 dollars each, and two fellowships of the annual value of $500 each. The fellowships are one in science and one in literature, which are open to competition by the senior class. The fellows are required to continue their studies for three years wherever they may choose, but under the direction of the president of the college. The law school was opened in 1858, since which time 930 students have graduated. The plan of instruction combines the study of selected text books with lectures. There are four professors, viz.: of municipal law, of constitutional history and public law, of ethics, and of jurisprudence and medical jurisprudence; and lectures are also delivered by prominent members of the New York bar. The course of study occupies two years, and a third year, or post-graduate course, has been organized for those students who may desire to pursue their studies beyond the regular course. Two moot courts, with a professor as presiding officer, are held every week of the term, at each of which a cause previously assigned is argued by six students. The term commences on the first Wednesday in October, and continues till May 15. Three prizes, aggregating $500, are annually awarded upon examination to such students as shall have attained the highest excellence in their respective classes. The tuition fees are $100 a year. The degree of LL. B. is conferred upon those students who have pursued the entire course of study, and have passed the requisite examination. By the provisions of an act of the legislature of New York, graduates of this law school are admitted to practice in all the courts of the state on receiving the college diploma.—The school of mines was established in 1864, and in 1873 had 21 professors and instructors. The course of instruction occupies three years. Those who complete it receive the degree of engineer of mines, civil engineer, or bachelor of philosophy. There is a post-graduate course of one year for the degree of doctor of philosophy, and a preparatory course for candidates not qualified to enter the first year. The year is divided into two sessions. The first commences on the first Monday in October; the second on the 16th of February. The lectures close on the last Friday of May, and are followed by an examination on the studies of the year. There are five parallel courses of study: 1, civil engineering; 2,

Columbia College.

mining engineering; 3, metallurgy; 4, geology and natural history; 5, analytical and applied chemistry. The plan of instruction includes lectures and recitations in the several departments of study; practice in the chemical and metallurgical laboratories; projects, estimates, and drawings for the establishment of mines, and for the construction of metallurgical and chemical works; reports on mines, industrial establishments, and field geology. Written and oral examinations are held at the end of each session. During the vacation, at the close of the first and second years, students are required to prepare and submit memoirs on subjects assigned to them by the faculty, and journals of travel, containing descriptions of mines and metallurgical or chemical works visited, and any interesting mineralogical or geological observations they may have made. The fee for the full course is $200 a year for each student; but those unable to pay may be admitted without charge. The library contains more than 2,000 volumes of works on science, besides the current literature of Europe and America relating to science. The various cabinets include 500 crystal models; 10,000 specimens of minerals; a complete collection of metallurgical products, illustrating the different stages of the typical processes in use in the extraction of each metal in Europe and America; an extensive collection of models of furnaces; several thousand specimens of materials and products, illustrating applied chemistry; and a geological collection embracing over 60,000 specimens.—The total amount invested by Columbia college for purposes of instruction is $591,850, in addition to which it owns real estate and personal property amounting to $4,184,426. The college debt in 1872 amounted to $1,240. The income for the year ending Sept. 30, 1872, was $240,405 12, and the expenditures were $172,240. The medical school is not included in these returns. The general library of the college in 1873 contained 16,364 volumes; law library, 3,860 volumes; library of the school of mines, 2,140 volumes; botanical library, 1,000 volumes. The herbarium, presented to the college by Dr. John Torrey, is valued at about $15,000, and the chemical and the philosophical apparatus at nearly $100,000. According to the triennial catalogue of 1870, the total number of graduates of all the schools was 3,834, of whom 2,721 were living. There were 2,109 graduates in arts, 868 in medicine, 487 in law, 37 in mining, and 333 honorary graduates. In 1873 there were 123 students in the academic department, 371 in the law school, 136 in the school of mines, and 359 in the medical school.—In 1746 an act was passed by the colony for raising £2,250 by lottery "for the encouragement of learning, and toward the founding of a college." By other similar acts this sum was increased in 1751 to £3,443, and vested in ten trustees, one of whom was a Presbyterian, two were of the Reformed Dutch communion, and seven were Episcopalians, some of whom were also vestrymen of Trinity church. In 1753 the trustees invited the Rev. Dr. Samuel Johnson, of Stratford, Conn., to become the president of the proposed college. The royal charter constituting King's college passed the seals Oct. 31, 1754, but the organization of the college under it was not effected till May 7, 1755, when the charter was presented by Lieut. Gov. De Lancey to the persons named in it as governors of the college, who consisted of the archbishop of Canterbury, the principal civil officers of the colony, the principal clergy of the five religious denominations in the city, and 20 private gentlemen. Money was collected in England, and books were sent out. The college, however, had opened July 17, 1754, with a class of eight, under Dr. Johnson's own instruction, in a vestry room belonging to Trinity church. The corner stone of the college building was laid Aug. 23, 1756, on the block now bounded by Murray, Church, and Barclay streets, and College place, and intersected by Park place. An English traveller described it as facing the Hudson, and being "the most beautifully situated of any college in the world." On June 21, 1758, the first commencement was held, when 10 bachelors and as many masters of arts were graduated. The students began to lodge and mess in the college building in May, 1760, and on June 26 the procession moved from there to St. George's chapel to hold the third commencement. At Dr. Johnson's request, the Rev. Myles Cooper, fellow of Queen's college, Oxford, was sent out in 1762 by the archbishop of Canterbury, and appointed fellow of the college, professor of moral philosophy, and to assist the president in instruction and government, with the understanding that he was to succeed him, which he did the following year. In 1767 a grant of land was made to the college of 24,000 acres, which was subsequently lost in consequence of lying in that part of the colony afterward set off to constitute a portion of Vermont. The instruction appears to have been conducted by the president and three tutors or professors, who were always able men, till 1767, when a faculty of medicine was created, consisting of six professors of great eminence. The chief studies were natural law, physic, logic, ethics, metaphysics, mathematics, natural philosophy, astronomy, geography, history, chronology, rhetoric, Hebrew, Greek, Latin, modern languages, and the belles-lettres. To the college was also annexed a grammar school for the due preparation of those who proposed to complete their education in the arts and sciences. Dr. Cooper was a strong loyalist, and had a pamphlet controversy with his pupil Alexander Hamilton. At length his politics became so obnoxious that the college was attacked by a mob in the night of May 10, 1775, and he was obliged to flee for his life. Six days after his escape the Rev. Benjamin Moore, afterward

bishop of the diocese, was made president *pro tem.* In 1776 the college was ordered by the committee of safety to be prepared for the reception of troops. The students were dispersed, the library and apparatus deposited in the city hall, and in consequence lost, and the building became a military hospital. Six hundred volumes were recovered 30 years after in a room in St. Paul's chapel, their existence having been known only to the sexton. The library had received, among great numbers of valuable presents, a copy of every work from the university press of Oxford. This state of things continued for eight years. In 1784 regents of a state university were appointed, of which the governor, Clinton, was chancellor, who demanded and received what property belonged to King's college, the name of which was changed to Columbia college by the same act which gave them the power. The regents organized four faculties: a faculty of arts, with seven professors; one of divinity, with such professors as might be established by the different religious societies within the state; a faculty of medicine, of seven professors; and one of law, of three. Besides all these, there were to be nine extra professors, a president, secretary, and librarian. For several years there was no president, his duties being discharged by the professors in turn. There were no funds to carry out the scheme of the regents. In 1787 the original charter was confirmed to Columbia college, and it was placed under the care of 24 trustees. These held their first meeting May 8, 1787, and on the 21st elected William Samuel Johnson, LL. D., son of the first president, and one of the most eminent lawyers and statesmen of the day, as president. In 1792 there was a full corps of professors, including one of oriental languages, one of natural history, chemistry, agriculture, and botany, occupied by Dr. Mitchill, and one of law, by James Kent. Dr. Johnson resigned in 1800, and was succeeded by the Rev. Dr. Wharton of Philadelphia. It is believed, however, that Dr. Wharton never entered upon the duties of the office. From this period the president took no part in the instruction, but exercised only a general supervision; and under this arrangement Bishop Moore accepted the presidency, Dec. 31, 1801. He did not reside in the college, nor on ordinary occasions take part in the discipline. In 1810 a new charter was obtained. In June, 1811, Bishop Moore having resigned, the Rev. William Harris was elected president, and the Rev. Dr. John M. Mason provost, the statutes of the college having been altered for the latter purpose. In 1812 Dr. Mason was also elected a trustee, a previous act of the legislature allowing it having been obtained. He was one of the most learned of the clergy of his time, and distinguished for the life and interest which he gave to the exercises of the lecture room. On Nov. 1, 1813, the medical school was incorporated with that of the college of physicians and surgeons. Dr. Mason resigned in 1816, and the office he held was discontinued. In 1817 the college received from the state the gift of the botanic garden ground, and a little after a grant of $10,000. In 1823 the Hon. James Kent delivered the course of lectures which were the basis of his celebrated commentaries. Upon the resignation of President Harris in 1829, William A. Duer, LL. D., was made president. He resigned in 1842, and was succeeded by Nathaniel F. Moore, LL. D., who was succeeded in 1849 by Charles King, LL. D. In 1830 the college opened a "scientific and literary course," accessible to others besides matriculated students, and professors were appointed in engineering, analytic chemistry, and other branches. This course was discontinued in 1843 for want of patronage. The power to endow and nominate to new professorships was extended to religious bodies and individuals, and some 20 free scholarships were constituted, to be in the gift of various religious and civil corporations in the city. In 1843 a professorship of German was founded by a bequest of $20,000 from Mr. Frederick Gebhard. In 1857 the college was removed to its present location in 49th street, the building formerly occupied by the institution for deaf mutes being fitted up for that purpose. The college grounds comprise the block bounded by Madison and Fourth avenues and 49th and 50th streets. In 1858 the law school was opened in Lafayette place. From 1813 to 1860 there was no faculty of medicine; but in the latter year it was revived by the adoption of the college of physicians and surgeons as the medical department of Columbia college. This college is situated on the corner of 23d street and Fourth avenue. The connection, however, is little more than nominal, as the medical college is governed by an independent board of trustees. In 1864 President King resigned, and was succeeded by the Rev. Frederick A. P. Barnard, LL. D., who still retains the office (1873). In 1872 the college purchased at a cost of $375,000 nearly ten acres of land near 160th street, on Washington Heights, extending from the Boulevard to the Hudson river, as a possible future site of the institution.

COLUMBIA (or **OREGON**) **RIVER,** a river of N. W. America, rising in Otter lake on the W. slope of the Rocky mountains, in British Columbia, in lat. 50° 30′ N., lon. 116° W. It flows N. W. to lat. 52° 10′, where it receives the Canoe, which rises in about lat. 52° 40′, then turns W. and S., and flows in a general S. direction to the boundary of the United States, whence, entering Washington territory, its course lies through the great plain between the Cascade and Rocky mountains to the 46th parallel. Here turning somewhat abruptly, it flows in a general W. direction, forming the boundary between Washington territory and Oregon, and falls into the Pacific in about lat. 46° 15′, lon. 124° W. There is a remarkable bend in lat. 47° 55′, lon. 118° 10′, where the river turns

nearly due W., and continues in that direction about 120 m. to the mouth of the Okinakane. It then flows S. W. about 50 m., when it turns S. E., and flows in that direction about 165 m. to the 46th parallel. Throughout its entire length the Columbia is very rapid, often passing through mountain gorges and broken by many cataracts. The tide sets up 165 m. to the Cascades, which are a series of rapids caused by the passage of the stream through the Cascade range. At a distance of about 30 m. from the ocean the river expands into a kind of bay from 3 to 7 m. wide, which forms its mouth. At low tide there is about 20 ft. of water over the flats at the entrance to this bay, while the depth of the channel is 24 ft. Ocean steamers can ascend to Vancouver, 115 m. above the mouth, and steamers of 200 or 300 tons to the Cascades, around which there is a railroad 6 m. long. The Dalles, 40 m. further, again obstruct navigation. Here the river bends like a horseshoe to the south, and flows with a rapid current through a basaltic trough with walls 20 ft. high and 200 yards apart. Other falls, with stretches of navigable water between, are Priest rapids, 179 m. above the Dalles; Buckland rapids, 66 m. further; and Kettle falls, 274 m. above. The last is a perpendicular fall of 15 ft. At high water (from the middle of May to the middle of July) steamers could probably ascend from the Dalles to Kettle falls. Above Kettle falls the river is again navigable about 50 m. to falls just N. of the 49th parallel. Above the head of Upper Arrow lake, lat. 50° 30′, there is no navigable water. At Vancouver the Columbia is a mile wide. Its total length is over 1,200 m. The rise at Vancouver during high water is 19 or 20 ft., and so great is the force of the current as to overcome the effect of the tide, and render the water drinkable even on the bar. The principal E. branches are the Kootenay (also called McGillivray or Flat Bow), which joins the Columbia in British territory about 20 m. N. of the boundary; Clarke's, or Flathead river; the Spokane; and Lewis fork (also called the Saptin or Snake river), which is the great southern tributary, and rises in the Rocky mountains in W. Wyoming, about lat. 44°, lon. 110° 30′. The tributaries from the west are smaller; the chief are the Nehoialpitkwu, Okinakane, and Yakama. Below the great bend several streams empty into the Columbia from the north, the largest of which is the Cowlitz; from the south it receives the Umatilla, John Day's river, the Des Chutes, and the Willamette.—Columbia river was discovered in 1792 by Capt. Robert Gray, who entered it May 11 of that year, in the Columbia Rediviva, of Boston, Mass. It was from this vessel that the river received its name. The first exploration of the Columbia was made in 1804–'5, by Captains Lewis and Clarke, under the direction of the war department.

COLUMBIANA, an E. county of Ohio, separated from Pennsylvania on the S. E. by the Ohio river, and drained by several streams; area, 490 sq. m.; pop. in 1870, 38,299. The southern portion is hilly, the northern level or gently undulating. The soil is fertile. Coal and iron are found. It is traversed by the Sandy and Beaver canal, and by the Cleveland and Pittsburgh, the Pittsburgh, Fort Wayne, and Chicago, and the New Lisbon railroads. The chief productions in 1870 were 270,190 bushels of wheat, 25,175 of rye, 566,242 of Indian corn, 653,001 of oats, 163,484 of potatoes, 45,301 tons of hay, 848,882 lbs. of butter, 573,561 of wool, and 602,978 of flax. There were 8,827 horses, 9,519 milch cows, 9,137 other cattle, 131,527 sheep, and 15,996 swine; 8 flour mills, 18 manufactories of stone and earthen ware, 6 of machinery, 1 of pig iron, 10 of iron castings, 4 of agricultural implements, 8 of bricks, 20 of carriages and wagons, 2 of hardware, 2 of lightning rods, 15 of saddlery and harness, 12 of tin, copper, and sheet-iron ware, 3 of woollen goods, 4 planing mills, 9 saw mills, 17 tanneries, and 16 currying establishments. Capital, New Lisbon.

COLUMBIUM, a metal extracted from the mineral columbite, found in Connecticut. It was first discovered by Mr. Hatchett in 1801, and is identical with the metal called by Rose niobium. Tantalum, afterward extracted by a Swedish chemist from the mineral tantalite, was long supposed, on the authority of Wollaston, to be the same substance, but is now known to be distinct from it. Columbium is of a yellowish white or gray color, and when burnished has a metallic lustre. The name was probably given from its being originally discovered in North America.

COLUMBO, or **Calumba,** the root of *cocculus palmatus* or *jateorrhiza palmata*, and of *J. calumba*, climbing plants of the order *menispermaceæ*, growing in Mozambique. The root is cut into transverse slices, which are from an eighth of an inch to near an inch in thickness, from one to two inches in diameter, and when of good quality of a tolerably bright yellow color in the cortical portion, somewhat lighter in the interior, and covered with a brownish wrinkled epidermis externally. Columbo contains a crystallizable neutral bitter principle, called colombine, and an alkaloid, berberina. Its medical virtues are those of a pure bitter, slightly if at all stimulating, and generally acceptable to the stomach. American columbo, the root of *Frasera Walteri*, of the order *gentianaceæ*, and a false columbo from *coscinium fenestratum*, belonging to the same order with the genuine, have been sold in Europe instead of the genuine.

COLUMBRETES, or **Colombretes,** a group of small islands in the Mediterranean, belonging to Spain, about lat. 39° 54′ N., lon. 0° 44′ E., 29 m. S. E. of Cape Oropesa. They are of volcanic origin, and very picturesque, their broken masses seeming like the fragments of a larger island. There is deep water between them, and a deep and capacious harbor in the

largest island, Santa Maria de Columbretes. On this island there is a hill of some elevation called Monte Colibre. The surface is much broken, and exhibits lavas and scoria, but there is an exuberance of dwarf olives, geraniums, prickly pears, myrtles, and brushwood, and crops are raised of rye, maize, pulse, potatoes, and hemp. The island swarms with snakes, which seem to be harmless. This group is important as a military station.

COLUMBUS, a S. E. county of North Carolina, bordering on South Carolina, bounded S. E. by the Waccamaw river, and N. W. by Lumber river; area, 600 sq. m.; pop. in 1870, 8,474, of whom 2,948 were colored. The surface is level and partly marshy. The Wilmington, Columbia, and Augusta railroad traverses it. The chief productions in 1870 were 65,972 bushels of Indian corn, 79,307 of sweet potatoes, 119 bales of cotton, and 216,964 lbs. of rice. There were 368 horses, 1,960 milch cows, 3,550 other cattle, 5,383 sheep, and 12,759 swine; 3 saw mills and 1 saddle and harness factory. Capital, Whiteville.

COLUMBUS, a city of Georgia, capital of Muscogee co., on the left bank of the Chattahoochee river, 300 m. above Appalachicola bay, and 95 m. S. S. W. of Atlanta; pop. in 1870, 7,401, of whom 3,204 were colored. It enjoys superior advantages for trade and great facilities for the erection of mills and factories. The Chattahoochee is navigable from Columbus to the gulf of Mexico during eight months of the year; and from the end of October to the 1st of July its waters are traversed by numerous steamboats laden with cotton. Opposite Columbus the river rushes over huge, rugged rocks, forming rapids, valuable for the excellent water power which they furnish, and in the improvement of which large sums of money have been expended. A dam 500 ft. long has been constructed at this point. A handsome bridge connects the city with Girard village, Alabama. Columbus is regularly laid out, with streets from 99 to 165 ft. wide. The principal public buildings are the court house, Presbyterian church, temperance hall, bank of Columbus, and two hotels. Three flour and grist mills are in operation, consuming annually 100,000 bushels of wheat and 60,000 of Indian corn. There are two banks, with $150,000 capital, and eight public schools, with 14 teachers and 545 pupils. Two daily and two weekly newspapers are published. The Southwestern (Georgia), the Mobile and Girard, and the Western (Alabama) railroads meet here. Columbus was laid out in 1828.

COLUMBUS, a city and the capital of Lowndes co., Mississippi, on the left bank of the Tombigbee river, which is navigable at all seasons, 25 m. S. of Aberdeen, and 132 m. N. E. of Jackson; pop. in 1870, 4,812, of whom 2,738 were colored. It has regular steamboat communication with Mobile. A branch railroad extends to Artesia on the Mobile and Ohio railroad. It is situated in a fertile region, and is the shipping place of large quantities of cotton. One tri-weekly and four weekly newspapers and a monthly are published. It contains a handsome court house, a United States land office, several churches, and a bank with $300,000 capital.

COLUMBUS, a town of Hickman co., Kentucky, on the Mississippi, 18 m. below Cairo, Ill.; pop. in 1870, 1,574, of whom 761 were colored. It is situated on the S. slope of a high bluff commanding the river for about 5 m. There is some trade in lumber. A weekly newspaper is published. The Mobile and Ohio railroad connects here by ferry with the St. Louis and Iron Mountain line. Columbus was strongly fortified by the confederates, who occupied it Sept. 4, 1861. They regarded it as the northern key to the mouth of the Mississippi, and had in the town and its vicinity about 30,000 men. After the capture of Forts Henry and Donelson by the federal troops in February, 1862, Columbus was abandoned by the confederate forces, March 2.

COLUMBUS, a city and the capital of Ohio, seat of justice of Franklin co., built mostly on the E. bank of the Scioto, just below the mouth of the Olentangy, in the centre of the state, 100 m. N. E. of Cincinnati. It lies in lat. 39° 57′ N., lon. 83° 3′ W., on the great alluvial plain which stretches from the E. part of Ohio to the Mississippi river, and has therefore no great natural features of mountain, lake, or sea to make it remarkable. Its growth and wealth are largely due to the concentration of the state institutions and the liberal expenditure of public money, together with the natural advantage of a rich country. Its population has been as follows: in 1820, 1,400; 1830, 2,437; 1840, 6,487; 1850, 17,882; 1860, 18,554; 1870, 31,274, of whom 7,611 were foreign born, and 1,897 colored. The streets are very wide, and are regularly laid out in squares. Broad street is 120 ft. wide for more than two miles, and is beautifully shaded with maple and elm trees. Many of the handsomest residences are in this street. High street, the principal business thoroughfare, is 100 ft. wide. Capitol square, which is beautifully laid out and surrounded with elms, occupies the square of 10 acres between High and Third and Broad and State streets, in the centre of the city. In it an artesian well has been sunk to a great depth. Goodale park, presented to the city by Dr. Lincoln Goodale, is at the N. end of the city, and contains about 40 acres of native forest, which has been improved. City park, at the S. end of the city, is similar in all respects to Goodale park. The grounds of the Franklin co. agricultural society, 83 acres in extent, on the E. border, are the finest in the state. The gardens of the Columbus horticultural society occupy 10 acres, in the vicinity of the agricultural grounds. Of the five cemeteries the most beautiful is Green Lawn. The most interesting feature of Columbus to the stranger is its numerous and important public

buildings and institutions. In this it is not excelled by any city in the United States except Washington, and much surpasses any other town of the Ohio valley. The state has concentrated here nearly all the public buildings devoted to its business, benevolence, or justice. The most conspicuous among these are the capitol, the penitentiary, the lunatic asylum, the deaf and dumb asylum, and the blind asylum. These are all on a large and liberal scale. The capitol is one of the largest in the United States. It is 304 ft. long and 184 in width, and covers 55,936 square feet. The rotunda is 157 ft. high and 64 ft. in diameter. The building is in the Doric order, of fine gray limestone, approaching marble in its texture and appearance, and is perhaps as fine a specimen of architecture as can be found in this country. The interior is elegantly finished. The hall of the house of representatives is 84 ft. long by 72½ ft. wide. The senate chamber is 56 by 72½. There are rooms for all the state officers, besides 26 committee rooms. All the arrangements for heat, light, water, and grounds are planned with the utmost improvement which modern skill has been able to invent. The penitentiary is another striking building. It is of hewn limestone, and with its yards and shops covers six acres of ground on the E. bank of the Scioto. Its entire front is 456 ft., the centre being 56 ft., containing the warden's house and offices, with two wings, each 200 ft. front and three stories high. These wings each contain 350 cells for prisoners, arranged in five tiers, and isolated from the main wall of the building by open galleries. The central Ohio lunatic asylum was burned in 1868. In 1870 a new series of buildings was commenced on 300 acres of elevated ground W. of the city. These buildings will be in the Franco-Italian style, with a frontage of about 1,200 ft., depth 300 ft., centre tower 165 ft. high, and a capacity for 600 patients. The asylum for idiots, a plain Gothic structure, 272 by 198 ft., occupies grounds 123 acres in extent, adjoining those of the lunatic asylum. The new blind asylum in the E. part of the city, on the grounds of the old one, will be a stone structure, 340 by 270 ft., in the Gothic style of the Tudor period. The deaf and dumb asylum, centrally situated on large and handsome grounds in Town street, is built in the Franco-Italian style. There is a large and well built state arsenal. The United States arsenal, situated on extensive and handsome grounds, beautifully wooded, in the N. E. suburb of the city, comprises, besides an immense central structure, numerous other buildings, used for offices, quarters, storehouses, &c. The city hall, on the S. side of State street, is a Gothic building, 187½ by 80 ft., with a central tower 138 ft. high. The high school building is a fine specimen of the simple Norman or church style of architecture. The Holly water works occupy a building 132 by 98 ft., near the junction of the Scioto and Olentangy rivers, and are abundantly supplied with machinery. The county buildings are the court house and a poorhouse, or county infirmary. There are also a fine opera house and a new odd fellows' building.—Columbus has great advantages for internal commerce. It is situated on a branch of the Ohio canal, at the intersection of the following railroads: Cleveland, Columbus, Cincinnati, and Indianapolis; Central Ohio; Pittsburgh, Cincinnati, and St. Louis; Little Miami; Columbus and Xenia; Columbus, Chicago, and Indiana Central; Cleveland, Mt. Vernon, and Delaware; Columbus and Hocking Valley. The last named road, opened in 1870, penetrates a very rich iron and coal region, and has given a great impetus to the business interests of the city. There are several lines of street railroad. The manufactures are important, the principal establishments being 7 founderies, 7 breweries, 10 machine shops, 8 planing mills, 7 tanning and currying establishments, 2 manufactories of agricultural implements, 3 of boilers, 2 of brushes, 3 of cars and car wheels, 17 of carriages, 7 of chairs, 3 of edge tools, 2 of files, several of furniture, 8 of hair work, 3 of lard oil, 3 of lime, 1 of paper, 3 of ploughs, 4 of pumps, 14 of saddlery and harness, 2 of soap, 1 of tools, 1 of wire work, 6 flour mills, 6 book binderies and blank book manufactories, 2 blast furnaces, 1 manufactory of bolts and nuts, 4 of boots and shoes, 1 of rope, 1 of saws, 3 of silver plating, and 2 rolling mills. There are 24 hotels, 3 national banks, with an aggregate capital of $650,000, 2 state banks, and 5 insurance companies, of which one is a life insurance association.—The city is divided into 9 wards, and is governed by a mayor and a common council of 17 members. The fire department is under the control of a chief engineer. There are 3 steam engines, a hook and ladder company, and 11 fire alarm boxes. In 1870 the penitentiary contained 1,053 prisoners and 72 officers and employees; the lunatic asylum, 320 patients; idiot asylum, 232; blind asylum, 193 patients and 30 employees and officers; and the deaf and dumb asylum, 266 inmates and 15 instructors. There are also several hospitals and orphan asylums. A convent of the sisters of the Good Shepherd has been established at Franklin, in the neighborhood. The board of education consists of a president, secretary, and one member from each ward. In 1871 there were two high schools, with 19 teachers and 621 pupils; and seven evening schools, with 43 teachers and 1,241 pupils. The other schools (grammar and primary) had 102 teachers and 4,003 pupils. The total expenditure on account of schools for the year was $121,255 27, of which $53,158 35 were for sites and buildings, and $53,759 92 for teachers' wages. The Roman Catholics have four parish schools, with an average attendance of 1,020, and several academies and seminaries. Other educational institutions are Capitol university (Lutheran), and Starling medical col-

lege, which in 1871 had 10 professors and 42 students. The Ohio agricultural and mechanical college, endowed with the congressional land grant, was opened in September, 1873. The state library contains over 36,000 volumes. There are two musical societies, two daily newspapers, four tri-weekly (one German), five weekly, and four monthly periodicals (two German). One of the weeklies, "The Mute's Chronicle," is published by the institution for the deaf and dumb. The churches, 44 in number, are as follows: 4 Baptist (one for colored people), 4 Congregational, 1 Disciples, 3 Episcopal, 2 Evangelical Association, 1 Friends, 1 Independent Protestant, 1 Jewish, 4 Lutheran (1 German), 9 Methodist, 5 Presbyterian, 4 Roman Catholic, 4 United Brethren, and 1 Universalist.—Columbus was laid out in 1812; it was incorporated as a borough in 1816, and as a city in 1834. It became the seat of the state government in 1816, and was made the county seat in 1824.

COLUMBUS. I. Christopher, the discoverer of America, born in Genoa, Italy, died in Valladolid, Spain, May 20, 1506. The time of his birth is uncertain. The earliest date given (1430), derived from a statement of Ramusio, is irreconcilable with admitted facts, and must be set aside. Peschel has recently endeavored to show that he was born in 1456, the ultimate evidence for which is a letter of Columbus, dated in 1503, stating that he was then 48 years of age. This is so much at variance with admitted facts that it seems probable that there is an error in writing (48 for 58, or even 68). Between 1435 and 1449 there is hardly a year which has not been fixed upon by different authors. Bernaldez, whose intimate connection with Columbus gives special weight to his statement, says that he died "at the age of 70 years (*setenta años*), a little more or less." This would fix the date at 1435 or 1436, which has been generally accepted. But D'Avezac has recently argued that instead of 70 (*setenta*) years should be read 60 (*sesenta*), and presents plausible reasons for the alteration. This would give the date of his birth at 1445 or 1446. Either date, 1435–'36, or 1445–'6, is reconcilable with ascertained data. According to the custom of the time, he Latinized his name of Cristoforo Colombo into Columbus, and when he went to Spain adopted the Spanish form of it, Cristóbal Colon. He was the eldest son of Domenico Colombo, a wool comber, and Susanna Fontanarossa. They had two other sons, Bartolommeo and Giacomo (the latter called in Spain Diego), and a daughter. Columbus having early evinced a decided inclination for the sea, his education was mainly directed to fit him for maritime life. Besides the ordinary branches, he was instructed in Latin, and made some proficiency in drawing. For a short time he was sent to the university of Pavia, where he studied geometry, geography, astronomy, and navigation. He then returned to Genoa, and assisted his father in his trade of wool-combing. When about 14 years of age he began his nautical career with a distant relative of the same name, an admiral in the Genoese service. Little is known of Columbus during the many years he spent at sea. He is supposed to have served in the naval expedition fitted out in Genoa in 1459 by John of Anjou, duke of Calabria, to make a descent upon Naples in the hope of recovering that kingdom for his father, King René; but he appears to have been principally engaged in commercial voyages on the Mediterranean and up the Levant. About 1470 he went to Lisbon, where he supported himself by making maps and charts. He also sailed occasionally in the expeditions to the coast of Guinea. Soon after he had settled at Lisbon he married Doña Felipa, daughter of Bartolommeo Moñis de Perestrello, an Italian cavalier, lately deceased, who had been one of the most distinguished navigators under Prince Henry, and had colonized and governed the island of Porto Santo. Columbus now resided for some time on that island, where his wife had inherited some property, and where his son Diego was born. Here he studied the papers, charts, and journals which had been left by his father-in-law; and here he was brought into association with persons interested in maritime discovery, among whom was Pedro Correo, a navigator of note, who had married the sister of the wife of Columbus. Columbus determined upon sailing west, not to discover a new continent, but to reach India by a new route; and his confidence in the practicability of this project was greatly enhanced by the recent application of the astrolabe to navigation. His theory, according to his son Fernando, was founded upon the nature of things, the authority of learned writers, and the reports of navigators. He set down as a fundamental axiom that the earth was a terraqueous sphere or globe, the circumference of which from east to west at the equator he divided into 24 hours of 15 degrees each, making 360 degrees. Comparing the globe of Ptolemy with the earliest map of Marinus of Tyre, he concluded that 15 hours had been known to the ancients, extending from the Canary islands to the city of Thinæ in Asia; and that the Portuguese had advanced the western frontier one hour more, by the discovery of the Azores and the Cape Verd islands; leaving 8 hours, or one third of the circumference of the earth, unknown and unexplored. This space might in a great measure be occupied by the eastern regions of Asia; and by pursuing a direct course from east to west through the intervening ocean, a navigator would arrive at the extremity of that country. This supposition was corroborated by the narratives of Marco Polo and John Mandeville, who in the 13th and 14th centuries had visited the remote parts of Asia, far beyond the regions laid down by Ptolemy; and also by the opinion of Strabo, who believed that the earth was surrounded by the

ocean which washed India on the east and Spain and Mauritania on the west. Moreover, various indications of land in the west had been found. A Portuguese pilot had taken from the water, 450 leagues west of Portugal, a piece of curiously carved wood, while a similar piece which had drifted from the same quarter was seen on the island of Porto Santo. Canes of tropical growth had been washed on the Madeiras, huge pine trees on the Azores, and even two drowned men, of appearance unlike Europeans, had been found on the island of Flores—all from the west. The precise time when Columbus first conceived the design of seeking a western route to India cannot be determined; but in the summer of 1474 he opened a correspondence upon this subject with Paulo Toscanelli, a learned cosmographer of Florence, who had already, in a letter to Alfonso V. of Portugal, expressed his views on a western passage to India. In reply to Columbus he said: "I praise your desire to navigate toward the west; the expedition you wish to undertake is not easy, but the route from the west coasts of Europe to the spice Indies is certain, if the tracks I have marked be followed." He also sent him a map projected partly according to Ptolemy and partly according to the descriptions of Marco Polo. On this map Asia was laid down in front of the western coasts of Africa and Europe, with a moderate space of ocean between them, in which were placed Cipango (supposed to be Japan), Antilla, and other islands. This map, by which Columbus sailed upon his first voyage of discovery, has been lost. In 1477 he made a voyage, apparently of exploration, to the northwest, 100 leagues beyond "the island of Thule," supposed to have been Iceland, into lat. 73°, where he was astonished to find the sea not frozen. Next he is reported to have visited the Portuguese settlement of San Jorge da Mina, on the coast of Guinea. It is asserted that Columbus first applied for aid in his undertaking to his native country, Genoa, but without success; and he is supposed to have vainly solicited the patronage of Portugal before the death of Alfonso. But the first application for royal patronage of which there is any clear and indisputable record was made to John II., who ascended the throne of Portugal in 1481. This monarch had imbibed the passion for discovery from his grand-uncle Prince Henry, and with his reign all its activity revived. King John seems to have received the proposition with favor, and referred it to a learned body charged with all matters relating to maritime discovery, and subsequently to a council composed of prelates and persons of the greatest learning in the kingdom, both of which treated the project as extravagant and visionary. Meantime he sent a caravel with the ostensible design of carrying provisions to the Cape Verd islands, but with secret instructions to pursue the route indicated by Columbus. After cruising for several days the caravel returned with the report that no indications of land had been seen. The king was not yet inclined to abandon the project, but Columbus, who had lost his wife and was now reduced to poverty, determined to abandon Portugal and seek elsewhere for patronage. Accordingly, with his son Diego, he left Lisbon for Spain toward the end of 1484, secretly, lest his departure should be prevented by King John, or, as some have asserted, by his creditors. He had already engaged his brother Bartolommeo to apply for aid to the king of England, though he does not appear to have entertained great hope from that quarter. It is said that Columbus after leaving Portugal made proposals to the government of Genoa for the second time, and also to Venice, which were declined. In 1485 he was in the south of Spain, where he endeavored to interest the dukes of Medina Sidonia and Medina Celi. The latter recommended the project to Queen Isabella, who requested that Columbus might be sent to her. Having arrived at Cordova, and while waiting for an opportunity to appear at court, Columbus became attached to Doña Beatriz Enriquez, by whom he had a son, Fernando, born in 1487, who became the historian of his father. Columbus followed the court to Salamanca, where he was introduced to the king by Pedro Gonzalez de Mendoza, grand cardinal of Spain, the most important personage about the court. Ferdinand heard him without disfavor, and referred the matter to a council of learned men, mostly ecclesiastics, under the presidency of the confessor of the queen. The conference assembled in the Dominican convent of San Estevan at Salamanca, but, instead of investigating the project on scientific grounds, controverted it by Scriptural texts; and it was not till 1491, after many renewed applications, that the commission reported "the project in question vain and impossible, and not becoming great princes to engage in on such slender grounds as had been adduced." Columbus, however, appears, during the seven years he attended the court, to have experienced personally the favor of the king and queen, and to have had frequent communication with them, although the king at least could not be brought to believe in his wonderful projects. The Spanish sovereigns were during this period engaged in the war against the Moors of Granada, and Columbus seems to have borne arms as a volunteer. A passage in Diego Ortiz's "Annals of Seville" incidentally mentions his bravery. Records are also extant of his having been provided with free quarters at the king's charge, with pay equal to his personal expenses. During this period of hope deferred, Columbus sustained himself with undiminished confidence. Endued with a poetic temperament, the auguries he sought for in the mystic language of the Scriptures gave a bias to his mind, which in his later years amounted almost to delusion. He sought in prophecy for assurance that the time had come when Christianity should be

extended to the ends of the earth, and came to regard himself as the destined instrument of Heaven for that end. While in this frame, and assisting at the siege of Baza, in December, 1489, two pilgrims having brought to the camp the threat of the sultan of Egypt to raze the tomb of Christ, Columbus registered a vow to devote the proceeds of his discoveries to rescue the holy sepulchre. In 1488 he received a letter from John II. of Portugal, inviting him to return. Henry VII. of England also invited him by letter to that country, and held out promises of encouragement. In 1491 he set out to lay his project before Charles VIII. of France, who had also written to him. On his way he stopped at the gate of the Franciscan monastery of La Rabida, near the seaport of Palos de Moguer in Andalusia, and asked for some bread and water for his boy. The prior of the convent, Juan Perez de Marchena, became greatly interested by the conversation of Columbus, and detained him as his guest. The mariners of Palos were then the most enterprising of Spain, and Juan Perez, himself a learned man, took much interest in their adventures. Dazzled by the stupendous projects described to him, but distrusting his own judgment, the worthy prior consulted with his friend Garcia Fernandez, physician of the village, and also with Alonso Pinzon, an experienced navigator of Palos. Pinzon was enthusiastic, and offered not only to advance money, but to command a ship. Perez had been the queen's confessor, and presuming on this sacred relation, he wrote a letter to Isabella, which he sent by the hands of Sebastian Rodriguez, an influential navigator of Palos, beseeching her to grant him an interview. Receiving a favorable reply, the prior mounted his mule at midnight, and rode to the camp at Santa Fé, where the king and queen were, and procured for Columbus an opportunity to explain his views personally. Isabella, on appointing an interview, considerately sent Columbus 20,000 maravedis (about $216), to put himself in condition to appear at court. Columbus related his story before the king and queen; but the terms upon which he insisted were characterized as exorbitant and ridiculous by the queen's confessor, Fernando de Talavera, archbishop of Granada, who had been appointed one of the negotiators; they were accordingly rejected. Columbus had left the royal presence, and was already two leagues from Granada on his way to Cordova, whence he intended to depart for France, when a messenger from the queen summoned him to return to Santa Fé. The brief space of time that had intervened gave to Spain the empire of the new world. When Columbus left the queen's presence, Juan Perez, Alonso de Quintanilla, Luis de San Angel, receiver of ecclesiastical revenues of Aragon, and the lady Beatriz, marchioness of Moya, remonstrated. Ferdinand coldly signified that the exchequer was empty. Isabella exclaimed, "I undertake the enterprise for my own crown of Castile, and will pledge my jewels to raise the necessary funds." The necessity of raising money by this means was obviated by San Angel offering to advance the funds on behalf of the crown of Castile, and 17,000 florins were advanced out of the treasury of Ferdinand. Accordingly, Columbus on his return had but to join their majesties in signing the agreement, on his own terms, as drawn up by Juan de Colonna, the royal secretary. This document, signed at Santa Fé, April 17, 1492, contained five articles: 1, that Columbus and his heirs male for ever should have the office of admiral over all lands he might discover, with honors equal to those of the grand admiral of Castile in his jurisdiction; 2, that he should be viceroy and governor general, with right to name governors for the sovereigns' approval; 3, that he should receive one tenth of the net value of all pearls, precious stones, gold, silver, spices, and merchandise obtained within his jurisdiction; 4, that he and his lieutenants should be the sole judges in all disputes that might arise between his jurisdiction and Spain; and 5, that he might at any time advance one eighth in any venture, and receive a corresponding share of the profits. A letter of privilege also permitted Columbus to take the title of don. The royal documents were signed both by Ferdinand and Isabella, but her separate crown of Castile defrayed all the expense; and during her life few persons except Castilians were permitted to establish themselves in the new territories. On May 8 young Diego was appointed page to Prince John, the heir apparent, and on May 12 Columbus took leave of the king and queen to superintend the fitting out of the expedition at Palos. He, with the aid of Perez and the brothers Pinzon, contributed an eighth of the expense. Trouble was found in procuring crews. Some were induced to join by four months' pay in advance, and by a decree that volunteers should be free from arrest for two months after their return. The complement was made up by impressment. Three ships, the Santa Maria, a decked vessel, and two caravels, or undecked boats, the Pinta and Niña, were fitted out. The Santa Maria was of 90 ft. keel and had four masts, of which two were square-rigged, and two fitted with lateen sails. It was decked from stem to stern, having besides a poop 26 ft. in length, beneath which was the armament of heavy guns, with small pieces forward, for throwing stones and grape. It was provided with eight anchors and carried 66 seamen. The other two vessels were of small size, which was considered an advantage for exploring rivers and coasts. Columbus commanded the Santa Maria; Martin Alonso Pinzon, having his second brother, Francisco Martin, for pilot, the Pinta; and the third brother, Vicente Yañez Pinzon, the Niña. Three other pilots were attached to the expedition, namely: Sancho Ruiz, Pedro Alonso Niño, and Bartolomé Roldan. Rodriguez San-

chez was inspector general of the fleet; Diego de Arana, principal alguazil; Rodrigo de Escobar, royal notary. There were also a surgeon, a physician, some few adventurers, and 90 seamen; in all, 120 souls. There were provisions for one year. Before leaving, Columbus, with most of his officers and crew, confessed to Juan Perez, and received the sacrament; and from the roads of Saltez, near Palos, on Friday morning, Aug. 3, 1492, they set sail on their expedition. They reached the Canaries without incident, except an accident to the Pinta's rudder, but hastened their departure from those islands, Sept. 6, on learning that a Portuguese fleet of three frigates was near, which the admiral was apprehensive might have been sent to intercept him. When night fell, and they lost sight of the last land on the margin of the sea of darkness, the full measure of their hardihood burst on the adventurers. Many wept, and declared they should never return. Columbus calmed their fears, and excited their cupidity by picturing the gorgeous regions of the east, drawing for descriptions on his imagination of Cathay. After leaving the Canaries the winds were light and baffling, but always from the east. On Sept. 11 they saw floating a tree, or mast, as of a vessel of 120 tons. On the afternoon of the 13th Columbus was startled to find a variance of the needle, which no longer pointed to the pole. The crew becoming alarmed, he invented a plausible theory about the attraction of the polar star, which quieted the pilots' fears. He also took observations of the sun every day with an astrolabe, and kept two logs, one correct for himself, and the other, showing a smaller progress, for his crew, thus keeping them in ignorance of the great distance they were from Spain. As they advanced, the oldest sailors were deceived by frequent indications of land. On the night of the 15th a meteor fell within five lengths of the admiral's ship. On the 16th the ships entered into the region of the trade winds. "This day, and all the following," says Columbus, "the air was so mild that it wanted but the song of nightingales to make it like the month of April in Andalusia." The same day they came into the sea of seaweed, yet known as the Sargasso sea; and on the 18th Martin Alonso, who had been ahead in the Pinta, assured Columbus that, from indications, they would see the land next day. The 19th was calm; they sounded, and found no bottom at 200 fathoms. On the 20th a change of wind to the S. W. cheered the crews with the belief that they were not urged forward by an ever-blowing east wind, against which it would be impossible to return. On the 23d was a storm, during which the crews insisted that the admiral should tempt Providence no further. On the 25th the wind became favorable. Columbus was studying a chart in his cabin, when Martin Pinzon cried "Land!" pointing to the S. W., where a dark mass was visible at the apparent distance of 25 leagues. The *Gloria in excelsis* was sung in all the ships, and the course was altered, only to find on the morrow that they had mistaken a cloud for the shore. For several days they sailed due west with a favoring breeze. On Oct. 1 Columbus estimated that he was 707 leagues from the Azores, and that in 40 more he would make some part of Asia. On the 7th the Niña gave the signal for land; but this was again an illusion. The crews had long been in a state of mutiny, often despairing, at other times turbulent, and even plotting to throw the admiral overboard. Columbus never swerved. Impressed by the one great idea of Asia to the westward, he refused to turn from the course, not even in search of islands which the pilots imagined to be near. During the 8th, 9th, and 10th they sailed W. S. W., following the flight of birds. On the 11th the Pinta picked up a piece of wood rudely carved, and the Niña a branch of thorn, with red berries. As night set in, the course was again changed due west. After evening prayer the admiral ordered a double watch to be set, and promised a silken doublet, in addition to the 10,000 maravedis guaranteed by the crown, to him who should first see the land. At 10 o'clock P. M. Columbus was seated on his deck, gazing wistfully seaward, when he saw a light. He called to Pedro Gutierrez, who also saw it, but Rodriguez Sanchez did not. No one slept that night. At 2 o'clock A. M. of Friday, Oct. 12, 1492, after having been 71 days at sea, the Pinta fired a gun, the signal for land. Rodrigo Triana, a sailor of the Pinta, was the first who saw the new world; but the reward was afterward adjudged to Columbus, for having previously perceived the light. When morning dawned a wooded island was seen about two leagues distant, with crowds of natives running along the beach. At sunrise, the boats being lowered, Columbus with the royal standard of Castile, and the brothers Pinzon bearing each a flag with a green cross, were rowed to the shore. Columbus first stepped on the beach. All knelt down, kissing the ground with tears and thanks to God. Then rising and drawing his sword, Columbus, as grand admiral and viceroy, unfurled the royal banner, took possession in the name of the crown of Castile, and named the island (one of the Bahama group) San Salvador. The astonished natives gazed in silence at their visitors, whom they imagined to be gods come down from heaven. Presents were exchanged of toys and trinkets for cotton yarn and cassava bread. Some of the natives, who wore ornaments of gold, on being interrogated whence the metal came, indicated by gestures a country in the south, whereon Columbus carried off seven of them and set out in search of this auriferous region, which he supposed to be Cipango. In the search, which proved fruitless as far as gold was concerned, he discovered the islands of Conception, Exuma, Isla Larga, and Cuba. The last he at first thought was the Cipango he

sought, but afterward concluded it was the mainland of India. He also discovered Hayti, which he thought was the Ophir of Solomon, but which he called Hispaniola, or Little Spain. On the bay, since called bay of Caracola, of this island, he built a fort with the timbers of the Santa Maria, and leaving in it 39 men, sailed on Jan 4, 1493, for Spain, taking with him several natives in the Niña, Martin Pinzon having already gone in search of gold on his own account in the Pinta. During the voyage a storm threatened the Niña with destruction. Columbus, fearful lest the knowledge of his discovery should perish, prepared a written statement of it, and heading it up in a cask committed it to the deep. On March 15, 1493, the ship reached the port of Palos, having a few days before been driven by storm into the Tagus, where he was favorably entertained by King John. The Spanish sovereigns, then at Barcelona, received him with great relaxation of court etiquette, ordered him to relate his adventures seated in their presence, confirmed all the dignities previously bestowed, and placed him in command of a fleet of 17 ships and 1,500 men, to prosecute the discovery. With this fleet he sailed from Cadiz, Sept. 25, 1493. From this day his good fortune forsook him. Many of those who sailed with him were adventurers in search of gold. Mutinies and quarrels broke out, and many of those who expected to find fortunes, but met nothing but disappointment, threw the blame on the admiral. Having discovered the Windward islands, Jamaica, and Porto Rico, and founded a colony in Hispaniola, of which he left his brother Bartolommeo *adelantado*, or lieutenant governor, he returned home against the trade winds, and reached Cadiz June 11, 1496. He was successful in clearing himself of the clamor against him. On some courtiers depreciating the value of his discovery, he invited them to make an egg stand on end. When they had exhausted their efforts to accomplish the feat, Columbus struck the egg on the table, breaking the shell, and thus left it upright. "Any one can do that!" cried the courtiers. "When I have shown you the way," replied Columbus, leaving them to make the application. Columbus sailed on his third voyage to the new world, May 30, 1498, from San Lucar de Barrameda, with six ships. On this occasion he kept further to the south, discovering the mouth of the Orinoco, which he imagined was the great river Gihon, having its rise in the garden of Eden; also the coast of Pará, and the islands of Trinidad, Margarita, and Cubaqua; then he bore away to Hispaniola, there to recruit his enfeebled health. He found the colony disorganized, and in his efforts to restore it became again the victim of malice and misrepresentation. A commissioner, Francisco de Bobadilla, was sent from Spain ostensibly to inquire into the difficulties. His first act was to put Columbus and his brother in chains, and send them to Spain. The account given of this indignity is touching. "Are you taking me to death, Vallejo?" inquired Columbus sadly, when that officer came to lead him from his cell. "Your excellency is to be conducted to Spain," replied the officer, whereupon the admiral relapsed into silence. The officers of the ship offering to liberate him from his fetters, he replied proudly that the chains had been put upon him by authority of their majesties, and he added, "I will wear them until they shall order them to be taken off, and I will preserve them afterward as relics and memorials of the reward of my services." The indignation expressed throughout Spain at this outrage caused the king to disclaim having authorized it; but it is evident that the nobles were jealous of the superior rank of the admiral, and the king dissatisfied with the unproductiveness of the new countries. After nine months' polite evasion of his entreaties for redress, Ferdinand appointed Nicolas Ovando governor of Hispaniola in his stead. Bobadilla had meantime been recalled, and was drowned on the way. The only subsequent employment of Columbus, now old, was the command of four caravels with 150 men, to search for a passage through the sea now known as the gulf of Mexico to the East Indies. He sailed from Cadiz, May 9, 1502; was refused permission to refit at his own colony, Hispaniola; coasted the south side of the gulf of Mexico; and after much suffering from famine and hardship returned home, reaching San Lucar Nov. 7, 1504. He lay sick some months at Seville, and recovered only to have his claims for redress finally rejected by the king, Queen Isabella being now dead. An old man, broken in body, although in full possession of his mental faculties, having, in his own words, "no place to repair to except an inn, and often with nothing to pay for his sustenance," the discoverer of the new world died, in the act of repeating the words, in Latin: "Lord, into thy hands I commit my spirit." Seven years afterward a marble tomb was placed over his remains, with an inscription ordered by the king:

Á Castilla y á Leon
Nuevo mundo dió Colon.

("To Castile and Leon a new world gave Colon.") Death did not end his voyages. His remains, first deposited in the convent of St. Francis, were transferred in 1513 to the Carthusian monastery of Las Cuevas; were taken in 1536 to Santo Domingo, and deposited in the cathedral of that city; thence were conveyed with great pomp in 1796 to the cathedral of Havana, where they now repose.—The character of Columbus is impressed on his life: lofty, daring, and ambitious in design, indomitable in conduct, moderate in success, undepressed in adversity, and in all imbued with a spirit of devotion. In person he was above the middle height, his countenance oval, with aquiline nose, bluish gray eyes, and fresh complexion. His hair had been auburn in youth,

but whitened early. The nobleness of his bearing commanded respect. He spoke fluently, and his conversation was vivacious, although at a later period, when he had been tried by misfortune, he says his "speech was abrupt and little amiable." In personal habits he was temperate, and toward his family entertained the warmest affection. His sons were more fortunate than himself. Diego sued the king in the high council of the Indies, and, recovering the viceroyalty of Hispaniola, married Maria de Toledo, niece of the duke of Alva. Their eldest son, Luis, exchanged the hereditary dignity of admiral for a pension and the title of duke of Veragua, marquis of Jamaica. Luis's eldest daughter married her cousin Diego, and died without issue, the male line thus becoming extinct. Finally the property and titles became in 1608 merged by marriage through the female line in a branch of the house of Bragança.—See Fernando Colon, *Historia del Almirante Cristoforo Colombo, suo padre* (Italian translation from the Spanish MS., Venice, 1571); *Navigatio Christophori Columbi* (Vicenza, 1507); *Codice diplomatico Colombo-Americano* (Genoa, 1523); Oviedo, *Historia general de las Indias* (1535–'7); Herrera, *Indias Occidentales* (1601); Robertson's "History of America" (1777); Bossi, *Vita di Colombo* (Milan, 1818); Navarrete, *Relacion de los quatro viajes de Cristóbal Colon* (1825); Washington Irving, "Life and Voyages of Columbus" (New York, 1828); Prescott, "Ferdinand and Isabella" (Boston, 1838); Schneidawind, *Christoph Columbus, Americas Entdecker* (1843); A. Harrisse, *Bibliotheca Americana Vetustissima* (New York, 1866); D'Avezac, *Année véritable de la naissance de Christophe Colombe* (in the *Bulletin de la société de géographie*, July, 1872). The complete works (*Raccolta completa*) of Columbus were published by Torre in 1864 (Lyons). **II. Bartolommeo,** elder brother of the preceding, born in Genoa about 1432, died in 1514. In 1470 he was established as a mariner and constructor of maps at Lisbon, whither many adventurous navigators had been drawn by royal patronage. He is believed to have visited the Cape of Good Hope with Bartholomew Diaz. It is not known how long he was absent when his brother sent him to England to seek the aid of Henry VII., but it appears certain that Christopher was ignorant of his fate, further than that he was captured by pirates. He did, however, attain the ear of the English monarch, and presented him with a map of the world, but it does not appear that he succeeded in procuring English aid. On his return through France he learned that his brother had already discovered the new world, and had sailed on a second voyage. Hastening to the Spanish court, he was received as became the brother of the admiral. Queen Isabella sent him in command of three store ships to the new colony of Hispaniola, where Christopher received him with joy, and appointed him *adelantado* or lieutenant governor of the Indies. In this position Bartolommeo showed great bravery and decision. He shared his brother's imprisonment, and with him was liberated on reaching Spain, where the Spanish monarchs confirmed his title, and gave him the lordship of the small island of Mona near Santo Domingo, with 200 Indians as his personal body guard. The fierce energy of his character, however, made them jealous of giving him too much latitude in affairs. He died childless.

COLUMELLA, Lucius Junius Moderatus, a Roman writer on rural affairs, flourished about A. D. 40. He was a native of Gades (Cadiz), but resided chiefly at Rome. His treatise *De Re Rustica* is one of the most valuable works on agriculture which have come down to us from antiquity. It is divided into 12 books, of which the 10th is in verse. The earlier editions of this work contain also his treatise *De Arboribus*, in one book. According to Pliny, Columella wrote a work on ancient sacrifices for obtaining the fruits of the earth, but this is lost. The *editio princeps*, printed in folio by Jenson at Venice, in 1472, and forming part of a collection of *Rei Rusticæ Scriptores varii*, is very rare. The most complete edition is contained in the *Scriptores Rei Rusticæ* of Schneider (4 vols. 8vo., Leipsic, 1794).

COLUSA, a N. county of California, bounded E. by the Sacramento river and W. by the Coast range of mountains; area, 2,376 sq. m.; pop. in 1870, 6,165, of whom 271 were Chinese. Several streams rise in the Coast range, but sink before reaching the Sacramento; Stony and Sycamore creeks traverse the county. Quicksilver, sulphur, and salt are found. The soil is fertile. The chief productions in 1870 were 701,174 bushels of wheat, 386,468 of barley, 11,214 tons of hay, and 1,086,599 lbs. of wool. There were 5,905 horses, and 231,537 cattle, sheep, and swine. Capital, Colusa.

COLVIN, Sydney. See supplement.

COLWELL, Stephen, an American merchant and author, born in Brooke co., W. Virginia, March 25, 1800, died in Philadelphia, Jan. 15, 1871. He was educated at Jefferson college, where he graduated in 1819; was admitted to the bar in 1821, and practised his profession for seven years in St. Clairsville, Ohio, and from 1828 to 1836 in Pittsburgh. He afterward became an iron merchant in Philadelphia, and a manufacturer of iron, first at Weymouth, N. J., and afterward at Conshohocken on the Schuylkill. He was an active member and officer of many philanthropic societies, a director of several railroads, a trustee of the Presbyterian general assembly, and a commissioner under an act of congress in 1865 "to inquire and report upon the subject of raising

by taxation such revenue as may be necessary to supply the wants of the government." He had long before made himself known as an original thinker and an able writer on political economy and other subjects. His principal writings, besides articles in reviews and magazines and reports from the revenue commission, are: "Letter on the Removal of the Deposits from the United States Bank" (1834); "New Themes for the Protestant Clergy" (1851); "Politics for American Christians" (1852); "Hints to a Layman" (1853); "The Ways and Means of Payment" (1859); "The Five Cotton States and New York" (1861); "Southern Wealth and Northern Profits" (1861); "The Claims of Labor and their Precedence to the Claims of Free Trade" (1861); "Gold, Banks, and Taxation" (1864); "Financial Suggestions and Remarks" (1867).—See "A Memoir of Stephen Colwell," by Henry C. Carey (Philadelphia, 1872).

COLZA OIL. See RAPE, a plant.

COMA (Gr. κῶμα, lethargy), a condition resembling profound sleep, in which the activity of the sensory ganglia is more or less completely suspended. The sensorium consists of the ganglionic masses lying along the basis of the skull in man, and partly included in the medulla oblongata, described in the article BRAIN, as the tubercula quadrigemina, olfactory lobes, corpora striata, and optic thalami, in which the nerves of special sense and of common sensation have their central terminations. In complete coma the activity of these ganglia is suspended, so that the individual is neither conscious of impressions derived from the organs of sense, nor has any perception of self-existence from the recognition of cerebral changes; shut off from the external world, and from internal sensation, his existence is to all intents and purposes a nonentity, a state of psychical annihilation. In the simpler forms of coma there is only a suspension, not a perversion, of the cerebral functions; but in the graver cases the accompanying delirium shows an affection of the hemispheres. Coma may be produced by congestion or hæmorrhage in the brain, by any abnormal pressure on this organ, by the agency of narcotic poisons and alcohol, by exhaustion from loss of blood, by concussion of the brain, and by action on the blood of various morbid products generated within the system. Slight coma differs but little from profound sleep; the heavy sleep of the drunkard, or that after severe and long mental or physical exertion, is almost comatose, the person being quite insensible to ordinary external stimuli; this condition cannot be regarded as disease, but as the rest required for the regeneration of the body by the slow and unobstructed performance of the nutritive processes; so in the coma from concussion or deficient supply of blood to the brain, the person cannot be aroused from his deep sleep without danger of violent and perhaps fatal reaction. Medical writers describe two varieties or stages of coma: *coma vigil*, in which the patient opens his eyes when spoken to, instantly shutting them again, with delirium, muttering, and agitation, as in unnatural wakefulness; and *coma somnolentum*, in which, after momentary revival, the patient sinks immediately into an apparently profound sleep; they are simply two different degrees of the same affection.

COMACCHIO, a fortified town of Italy, in the province and 28 m. S. E. of the city of Ferrara, 3 m. from the Adriatic; pop. about 6,500. It is the seat of a bishop. The chief occupation of the inhabitants is pisciculture. A series of canals has been constructed to connect the lagoon in the midst of which the town is situated with the Adriatic, so as to admit the fry of the eel, the mullet, the sole, and other fishes into the lagoon, where they are fattened. The annual product now averages 1,000,000 lbs. The manufacture of salt is also of importance, about 2,000,000 lbs. being obtained annually.

COMAL, a S. W. central county of Texas, bounded S. W. by the Cibolo river, and intersected by the Guadalupe; area, 575 sq. m.; pop. in 1870, 5,283, of whom 377 were colored. The surface is rolling, and in some parts mountainous; live oak and mezquite cover about one third of the land. The soil is fertile in the valleys, but fit only for grazing elsewhere. The county was settled by Germans. The chief productions in 1870 were 169,250 bushels of Indian corn, 3,972 of rye, 8,913 of sweet potatoes, 1,309 tons of hay, 69,305 lbs. of butter, and 1,303 bales of cotton. There were 3,993 horses, 5,978 milch cows, 15,413 other cattle, 1,783 sheep, and 2,671 swine; 1 cotton and woollen mill, 3 flour mills, 1 saw mill, 5 tanneries, and 15 manufactories of saddles and harness. Capital, New Braunfels.

COMANA. I. An ancient city of Cappadocia (supposed to be the modern Bostan), on the river Sarus, celebrated in antiquity for its temple of Ma (the moon-goddess), or according to others of Enyo (Bellona), and for the great devotion of its inhabitants to the worship of that goddess. Over 6,000 persons were engaged in the service of the temple. The city was governed by the high priest, who was always a member of the reigning family, and took rank next to the king, if he did not exercise royal functions himself. **II.** A city of Pontus, on the river Iris, devoted to the same goddess as the Cappadocian Comana, of which it was believed to be a colony. On its site is now Gümenek, about 7 m. N. E. of Tokat, and about 70 m. S. S. E. of Samsun on the Black sea.

COMANCHE. I. A N. W. central county of Texas, intersected by Leon river; area, 1,050 sq. m.; pop. in 1870, 1,001, of whom 24 were colored. A mountain ridge forms its S. W. boundary; the rest of the surface is generally undulating and well timbered, about a third part being covered with oak, ash, elm, &c. The soil is fertile in the river bottoms, but unproductive in other places. Stock raising is the leading occupation. The native mustang grape

is abundant. The chief productions in 1870 were 3,368 bushels of wheat, 39,292 of Indian corn, 1,722 of sweet potatoes, and 28 bales of cotton. There were 275 horses, 17,246 cattle, and 5,337 swine. Capital, Comanche. **II.** A S. W. county of Kansas, bordering on the Indian territory; area, 780 sq. m.; yet unsettled. It is intersected by the Nescatunga and Cimarron rivers.

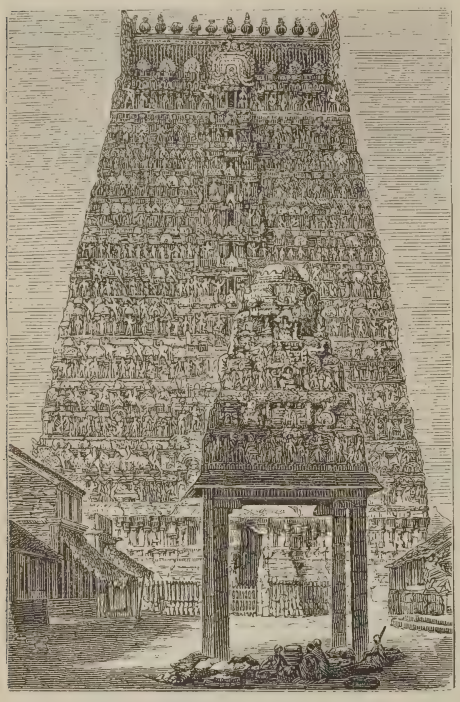
COMANCHES, a tribe of American Indians belonging to the great Shoshone family. They are a roving race, living in skin lodges with no fixed villages, roaming when first known from the head waters of the Brazos and Colorado to those of the Arkansas and Missouri, and in some bands penetrating to Durango in Mexico and to Santa Fé in New Mexico. They are great hunters and warriors, and have been at war with the Spaniards, and with the Osages, Pawnees, and other tribes of the plains, from

A Comanche Warrior.

an early period. Their traditions are vague, but they claim to have come from the west. They believe in a supreme being called Niatpo (my father), and have medicine men called *puhacan*. They call themselves Naiini ("live people"); but the Kansas called them Padoucas, the name adopted by the French, and the Spaniards Comanches, a term adopted in the United States. They are divided into eight bands. The Comanches have a martial air, and, though rather heavy and ungraceful on foot, are splendid on horseback. They procured horses from the Spaniards at an early day by theft, accident, or purchase, and becoming expert riders acquired additional power. —The French under Dutisné first reached their country in 1719, and began to buy horses from them. In 1724 an expedition under De Bourgmont visited their principal bands and made a treaty with them. They were then scattered over a tract of 200 leagues, those near the Spaniards in villages more or less fixed, those remote moving as game required. One village visited by De Bourgmont contained 140 lodges, 800 warriors, 1,500 women, and 2,000 children. Both sexes were then and have always been more decently dressed than Indians generally, the men wearing a regular pantaloon and good moccasins, those of the women extending up till they reached the tunic. They had long and bloody wars with the Spaniards till Anza in 1783, in a vigorous campaign, defeated and killed 30 chiefs, among them the great war chief Tabivonaritgante, called by the Spaniards Cuernoverde. This established peace for some time, and a chief named Maya sent his son to Mexico, who after receiving a little education returned to succeed his father, and thus kept up the good feeling. Morfi, the historian of Texas, about 1780 estimated them at 5,000 warriors. In 1816 they lost 4,000 by smallpox, and in 1822 were estimated at about 9,000 in all; but Catlin some years later put their numbers much higher. President Burnet in 1847 estimated them at 10,000 or 12,000, 2,000 or 2,500 being warriors. They have always been dangerous and troublesome. They were at one time on a reservation in Texas, but were expelled and have since been unrelenting enemies of that state. The United States government has collected some of them on a new reservation in the western part of the Indian territory. One part, the Quauhada, or Staked Plain Comanches, ridicule the idea of settling down, but were chastised by Col. McKenzie at McClellan's creek in 1872. The Comanches were estimated in 1872 at 3,218, the roving bands numbering perhaps 1,000 more. Their individual property was estimated at $400,000. They have consequently lost greatly, their numbers not being recruited as formerly by young Mexican captives of both sexes.

COMAYAGUA. I. A department of Honduras, Central America; area, 4,800 sq. m.; pop. about 75,000. It occupies the S. central portion of the state, and consists chiefly of the plains of Comayagua and of Espino, both watered by the Humuya river. In the S. E. part are the mountains of San Juan or Guajiquero, occupied exclusively by Indians descended from the aboriginal Lencas, who cultivate the cereals and the fruits of the higher latitudes, and raise a fine and hardy race of mules. The soil is rich, and the plains are well adapted for the production of cochineal, coffee, and the other staples of semi-tropical regions. Like the rest of Honduras, it possesses great mineral wealth, which however is neglected from want of enterprise and capital. Rich silver mines exist in the mountains, and copper ores abound. There are also vast deposits of blue and veined marble and inexhaustible beds of ochre of various colors and fine quality. Pine and oak abound on the hills, and mahogany, cedar, lignumvitæ, and other useful woods are found in the valleys.

The district is famed for its superior breed of cattle. Among the principal towns are Las Piedras or Villa de la Paz, Villa de San Antonio, Opoteca, Espino, San Antonio del Norte, Goascoran, and Caridad. **II.** The capital of the department and of the state of Honduras, situated on the S. border of the plain of Comayagua, in lat. 14° 28′ N., lon. 87° 39′ W., on the Humuya river; pop. about 12,000. It is very nearly midway between the two oceans. Previous to 1827 it was a flourishing town, embellished with fountains and monuments, and having many fine buildings; but in that year it was taken and burned by the monarchical faction of Guatemala, and it has never since recovered. It is the seat of a bishopric, and has a large cathedral, a university, a hospital, and several churches and convents. Its trade is small on account of the difficulty of communication with the coast; but as it is on the route



Comayagua.

of the interoceanic railway now building from Puerto Cavallos to the bay of Fonseca, it will probably increase in importance. Comayagua was founded in 1540 by Alonso Cáceres, and originally called Valladolid. The country around it has many remarkable ruins, and bears evidences of having sustained in ancient times a large and flourishing population.

COMB (Sax. *camb*), an instrument of wood, horn, shell, ivory, or other material, cut on one or both sides into a series of teeth, serving to disentangle and adjust the hair, and often worn by women as an ornament to the head, or to retain the hair in place. Its invention belongs to the remotest antiquity. The combs of the ancient Egyptians were usually of wood, having on one side large, and on the other fine teeth, the central portion being sometimes inlaid or ornamented with carved work. When having but a single row of teeth, the opposite side was often surmounted by a figure of the ibex or some other animal. They were about four inches long and six deep, the teeth on either side being over two inches in length. The Greeks, who dressed their hair with great care, used combs made of boxwood obtained from the shores of the Euxine. Golden combs were ascribed by the poets to the goddesses. Three combs, similar to modern small-tooth combs, are represented on the Amyclæan marbles. Roman combs, like the Greek, were made of boxwood, especially that obtained from the mountains of Cytorus, in Asia Minor, and remains of them have been found at Pompeii. Wood long continued the common material for combs, but during the later middle ages horn, ivory, and gold were sometimes employed, and pearls and precious and artificial stones were added for ornaments; and the comb was thus made an elegant part of the coiffure. Some modern sculptors, as Canova, have introduced it with fine effect as a part of feminine costume in statuary.—Ornamental combs of gold or silver have often been in general use by women; but the material longest and most commonly employed for this purpose is tortoise shell. The pieces of shell, as found in commerce, are never of suitable forms for combs. They are therefore softened with boiling water and put between iron or brass moulds of the desired shape until they cool. The place for the teeth is next marked. The interstices of the teeth were formerly cut with a thin steel saw, but a machine has been invented in which, by means of pressure, two combs are cut at the same time from the same strip of shell or ivory. The sides of the strip are to be the backs of the two combs, the teeth lying in the middle portion. The strip is fastened to a carriage, which is moved forward until it comes under the action of a ratchet wheel toothed upon a part of its circumference. The teeth of this wheel bring down a lever furnished with a chisel, which cuts out the two combs from the flat piece, the teeth of one lying between those of the other. This process is called parting, and is performed very rapidly and with great precision. So delicate are some of the saw machines, that from 80 to 100 teeth may be cut in an inch of ivory. Combs are now manufactured from vulcanized India rubber.

COMBACONUM, or **Kumbakonam,** a city of British India, in the Carnatic, 20 m. N. E. of Tanjore; pop. about 40,000. It is a place of great antiquity, is esteemed a holy city, and has several pagodas, gateways, and water tanks of

very superior construction. One of these tanks is said to be filled every 12th year by the waters of the Ganges, 1,200 m. distant, which enter the reservoir by a subterranean channel.

Great Gopura at Combaconum.

This water is held capable of purifying from sin and uncleanness every one who bathes in it, and thousands journey thither at the proper season to participate in its benefits. The great gopura or gate pyramid, at one of the entrances to the town, is referred to by Fergusson in his "Architecture" as one of the most imposing structures of its class. It has 12 stories, the lowest of granite, and the others of brick covered with the most elaborately ornamented stucco. A multitude of figures of men and animals cover it from top to bottom, forming a mass of peculiar ornamentation which greatly detracts from the imposing effect of the whole.

COMBALOT, Théodore, abbé, a French priest and author, born at Châtenay (Isère), Aug. 21, 1798, died in Paris, March 15, 1873. He studied philosophy and theology, was ordained priest in 1821, and acquired celebrity as an eloquent ultramontane preacher. Pope Gregory XVI. appointed him apostolic vicar, and in the latter part of his life he was vicar general of Rouen, Arras, and Montpellier. In 1844 he was sentenced to a month's imprisonment in consequence of his violent *Mémoire adressé aux évêques de France et aux pères de famille sur la guerre faite à la société par le monopole universitaire.* His other writings include *La connaissance de Jésus-Christ*, &c. (4th ed., 1852); *Conférence sur les grandeurs de la Sainte Vierge* (1845; new ed., 1854); and *Nouvelles conférences prêchées à Paris, à Lyons, en Belgique*, &c., *depuis le décret dogmatique de l'immaculée conception* (2 vols., Lyons, 1864).

COMBE. I. George, a Scottish phrenologist, born in Edinburgh, Oct. 21, 1788, died at Moor Park, England, Aug. 14, 1858. He studied law, and continued in practice till 1837, when he resolved to devote himself to science. On the visit of Spurzheim to Edinburgh in 1816 Combe became a convert to his system of phrenology, and advocated it in his lectures and writings. In 1819 he published "Essays on Phrenology, or an Inquiry into the System of Gall and Spurzheim," which was subsequently developed into his "System of Phrenology" (2 vols. 8vo, 1824). His principal work, "The Constitution of Man considered in relation to External Objects" (1828), produced a wide and deep impression. It has passed through numerous editions and been translated into several languages. The object of this work was to show that the intellectual and moral procedure of man, as well as the physical procedure of the universe, is regulated by natural laws which must be studied in order to carry out successfully his physical, moral, and social improvement. In 1823, assisted by a few friends, George and Andrew Combe established the "Edinburgh Phrenological Journal," and for more than 23 years gratuitously contributed to its pages. In 1833 he married a daughter of Mrs. Siddons, the celebrated actress. In 1837 he visited Germany; and in 1838, accompanied by his wife, he visited the United States, delivered 158 lectures in various parts of the country, and returned home in June, 1840. In 1842 he revisited Germany, and in the summer of that year delivered in Heidelberg a series of lectures on phrenology, in the German language. He was the first to spread a knowledge in England of the new religious movement in Germany, of which Ronge was the chief leader, by writing "Notes on the Reformation in Germany" (London, 1845). Among his other works are: "Elements of Phrenology" (1824); "Lectures on Popular Education" (1833); "Moral Philosophy, or the Duties of Man, Individual, Domestic, and Social" (1840); "Notes on the United States of America" (3 vols., 1841); "Thoughts on Capital Punishment," and "Remarks on National Education" (1847); "Principles of Criminal Legislation and Prison Discipline Investigated" (1854); "Phrenology applied to Painting and Sculpture" (1855); and "Relation between Science and Religion" (1857). **II. Abraham,** elder brother of the preceding, born Jan. 15, 1785, died Aug. 11, 1827. He was a disciple of Owen, and sacrificed his fortune in establishing "the coöperative society" in Edinburgh, in furtherance of his socialistic theories. Long after this had failed, he made

a new attempt in 1825, by forming a similar establishment on a large scale at Orbiston, near Glasgow, which however proved unsuccessful. He wrote "Sketches of the Old and New Systems," and "The Religious Creed of the New System." **III. Andrew,** a Scottish physician and author, brother of the preceding, born in Edinburgh, Oct. 27, 1797, died there, Aug. 9, 1847. He studied medicine in Edinburgh and Paris, and began practice in Edinburgh in 1823. In 1836 he was appointed physician to King Leopold of Belgium, and afterward physician in Scotland to Queen Victoria. He contributed largely to phrenological and medical journals. His principal works, all of which have passed through many editions, are: "Observations on Mental Derangement" (1831); "Principles of Physiology" (1834); "The Physiology of Digestion" (1836); and "The Management of Infancy" (1840). His death was hastened by exposure to the vitiated atmosphere of an emigrant ship in which he made a voyage to America; the knowledge which he gained on this voyage was embodied in a letter to the "Times," published a month after his death, which led to the passage of a law regulating the sanitary arrangements in emigrant vessels. His "Life and Correspondence" was published by his brother, George Combe (2 vols., Edinburgh, 1850).

COMBERMERE, Stapleton Cotton, viscount, a British soldier, born in Denbighshire, Nov. 17, 1773, died at Clifton, Feb. 21, 1865. He entered the army at an early age, and served in India in the war against Tippoo Saib. In 1808 he was sent to the peninsula in command of a brigade of cavalry, and participated in nearly all the great actions, from Talavera to the close of the war. In 1810 he was appointed to the command of the whole allied cavalry under the duke of Wellington. He was repeatedly thanked by parliament for his services, and upon the conclusion of peace was elevated to the peerage. He was afterward governor of Barbadoes, and commanded the British forces in India from 1822 to 1826. He also distinguished himself at the capture of Bhurtpoor (1826), for which he was made a viscount. In 1834 he was made a privy councillor, and in 1852 succeeded the duke of Wellington as constable of the tower of London and lord lieutenant of the Tower Hamlets. In 1855 he became field marshal.

COMBES, Edmond, a French traveller, born June 8, 1812, died in 1872. He was vice consul at Scala Nova, Asia Minor, and at Rabat, Morocco; explored the coasts of the Red sea, a portion of Arabia, Abyssinia, and E. Africa, where he was the first to ascertain the altitude of the mountains of the Moon; and in 1841 he travelled in Nubia and Egypt. With his companion, M. Tamisier, he published *Voyage en Abyssinie, dans les pays des Gallas, de Choa et d'Ifat, précédé d'une excursion dans l'Arabie Heureuse* (4 vols., Paris, 1837–'8).

COMBINATIONS, Theory of, in mathematics, a statement of the laws which determine the possible variations in the grouping of any number of given signs. The signs and groups are known as elements and forms. There are three processes of combination. The first, which is termed permutation, consists in changing the order of the given elements so that the same arrangement is never repeated. The second, which is specially termed combination, consists in arranging the elements into partial groups, so that, without regarding the arrangement, precisely the same elements are not repeated in any form. In permutation, all the elements are contained in each form. In combination, each form may consist of two, three, or any other number of elements less than the whole number given. The third process, termed variation, is a union of the other two. It consists in first making all the forms possible by combination, and then multiplying each of these forms by permutation. In permutation there is a change in the order; in combination, in the contents or matter; and in variation, in both. The complication and possible number of forms is greatly increased when the elements are repeated. The theory of combinations has application to ideas, sounds, colors, and even to food and other material compounds; but its principal use is in mathematical analysis and in the calculation of chances. The first important contribution to its development was by Buteo (1559), who represented all the throws possible with four dice. Pascal applied it to games, Mersenne to musical tones, and Guldin reckoned the number of words which could be formed from 23 letters. Leibnitz recognized its significance, and sought in vain to make use of it in discovering philosophical truths. Bernoulli and Euler labored upon it, but the first who gave it a scientific character was Hindenburg in 1778; and it was subsequently developed by Lagrange, Laplace, Poisson, Pfaff, Eschenbach, and Rothe. See *Lehrbuch der combinatorischen Analysis*, by Weingärtner (Leipsic, 1800–1801), and *Vollständiger Lehrbegriff der reinen Combinationslehre*, by Spehr (Brunswick, 1824).

COMBS, Leslie. See supplement.

COMBUSTION, a chemical process, in which bodies combine to form a new compound, with the evolution of heat, and usually light. In ordinary cases of combustion, oxygen is one of the combining bodies, and the substance with which it unites disappears with it in a gaseous form. It was formerly regarded as an essential element in combustion, but the phenomena of light and heat, characteristic of rapid combustion, are observed when chlorine combines with phosphorus and with some metals when these are in a powdered state; also in the action of cyanogen and potassium, and of sulphur upon iron filings and copper leaf. Some bodies also burn in the vapors of iodine, bromine, and fluorine. As commonly witnessed, combustion is a process taking place in the presence of atmospheric air, which furnishes the oxygen to support it; and it is conducted, not, as most other chemical operations are, for the sake of its products, but

for the phenomena which attend it. The development of these depends upon the rapidity with which it goes on, and this distinguishes it from the other cases of oxidation, which are sometimes called slow combustion, as when metals rust, spirituous liquors turn to acetic acid, and the blood by respiration is oxidized. The views which prevailed respecting the nature of combustion before the discovery of oxygen gas by Priestley in 1774, and the development of its properties by Lavoisier in the succeeding year, were necessarily incorrect. With the ancients, fire was an element that devoured other bodies and converted them into itself. Dr. Hooke in 1665, and Mayow soon after, advanced the opinion that there existed in the air a "nitrous spirit," which dissolved bodies susceptible to its influence when their temperature was suitably raised, and that the light and heat were the sensible effects of the rapid motions taking place. This theory, though close to the truth, was for a long time lost sight of in the general acceptance of the celebrated phlogistic theory, which was advanced soon afterward by Becher, professor at Mentz, and ably sustained by Stahl, professor at Halle. They considered that in combustion a certain element, which Stahl named phlogiston (from Gr. φλογίζειν, to burn), left the burning body, and the product was this body deprived of its phlogiston, by regaining which it was restored to its original character; as sulphur or phosphorus when consumed became sulphuric or phosphoric acid, and on regaining their phlogiston were again sulphur or phosphorus. It was known that the earthy "calx," into which some of the metals were transformed by fire, gained rather than lost weight; but this was explained by attributing to phlogiston a principle of levity. Notwithstanding the defects of the theory, it was still an important step in the progress of chemical science, serving first to group correctly together the phenomena of combustion, acidification, and respiration. Its nomenclature was incorporated with the science, and when Priestley made his great discovery of the new kinds of air, he gave to nitrogen, which he supposed to be a combination of air with the phlogiston of the combustible, the name of phlogisticated air, and to oxygen or pure air that of dephlogisticated air. Lavoisier, by subjecting the products of combustion to the test of weighing, showed that the combustible gained weight by the process, and he proved, on restoring it to its former condition (as in the case of a metallic oxide), that the substance taken up and given out again was the pure air of Priestley, to which he gave the name of oxygen, from its acidifying property (ὀξύς and γεννάω). Thus was established the antiphlogistic theory, that in every case of combustion oxygen combines with the burning body. Dr. Black's theory of latent heat was adopted to account for the production of light and heat; the latter being evolved or rendered sensible when substances without change of form pass from a rarer into a denser state, also when a gas becomes liquid or solid, or a liquid solidifies. The oxygen of the air was supposed to contain heat and light in a latent state, which were evolved with its change into a more condensed form, and the products of combustion were supposed to have less combined or specific heat than the original substances. But this application failed in the case of combustion of solid bodies by explosion, the gaseous compounds expanding in some instances to 2,000 times their original bulk, and yet producing intense heat instead of cold, as the theory would require; and the specific heat of the new compounds, in this as in the combustion of charcoal, it was shown by Dulong and Petit, was often quite equal to, and sometimes exceeded, that of the combining bodies, and this, moreover, bore no relation to that evolved in combustion. Davy considered that the burning body and the supporter of combustion were in opposite electrical conditions, and that the heat and light were evolved in the discharge of these electricities; which view was also held by Berzelius, though unsustained by any positive proof. Despretz ascertained the number of pounds of water which the burning of 1 lb. of different combustibles would heat from the temperature of 32° to 212° F. The following are some of his results:

1 lb. of	Lbs. of water.
Pure charcoal	78
Charcoal from wood	75
Baked wood	36
Bituminous coal	60
Wood containing 20 per cent. of water	27
Turf	25 to 30
Alcohol	67·5
Olive oil, wax, &c	90 to 95
Ether	80
Hydrogen	236·4

Carbon and hydrogen are the two common elements, which by uniting with oxygen produce combustion. They are furnished in a variety of forms suitable to this application, the source of all which is traced to vegetable growth; and this ever continues to gather up the products of combustion, and, separating them by decomposition, places them again in condition to renew the process. In combination they assume a volatile form, and float upward with the air rarefied by the heat, thus allowing the admission of fresh supplies of oxygen to constantly reach the ignited body. Though the combustible bodies are enveloped in the atmospheric air, and are ever disposed to unite with its oxygen, the process cannot commence until the temperature of the combustible has been raised to a certain point, when it is said to catch fire; the process thus begins, and afterward evolves the heat necessary for its continuance.—The condition of the air as to temperature, density, and the presence of aqueous vapor, variously affects the process of combustion. Increase of density adds to the quantity of oxygen in a given volume, and consequently may be expected to increase the rate of combustion. The effect of

temperature is less understood, but so far as it diminishes the density of air it must retard combustion. A sensible difference is perceived in the rate of combustion of large fires connected with metallurgical operations in summer and winter, which is no doubt correctly attributed to the volatile products of combustion not so freely quitting the burning bodies to rise up in the rarefied air of summer as in the denser winter atmosphere, and thus retarding the operations. Aqueous vapor in some circumstances is found to retard combustion, in others to accelerate it. Unless subjected to the degree of heat necessary to decompose it, it takes the place of atmospheric air, and diminishes the proportion of effective oxygen present. Steam is employed as an active agent for extinguishing fires, and also in small quantity to increase their effect. For this purpose a jet of steam is discharged under the grate bars of a furnace, or the ash pit is made a reservoir for water, which is evaporated by the heat radiated downward, and the vapor carried up by the draught is decomposed in passing through the incandescent coals. Its oxygen takes up a portion of carbon, forming carbonic oxide, which, as it meets more oxygen, is converted into carbonic acid gas with the production of much heat. So its hydrogen seizes a portion of the highly heated carbon, and is converted into carburetted hydrogen, or in part escapes, till meeting an equivalent of oxygen it is burned with the reproduction of water. It was shown by the numerous experiments of Bunsen and Fyfe that a considerable increase of heat was thus gained over that consumed in the decomposition of the vapor. Its use, however, in practical operations, demands the exercise of some judgment; for in excess, or with insufficient supplies of air, its effect would be the reverse of that intended. So also the vapor should be made to come up through the bars, and not be raised from among the coals at the cost of a portion of the available heat generated by their combustion.—An opinion has long been current, and not among the unlearned alone, that combustion was retarded by the light of the sun shining upon the fire. This apparent effect is accounted for by some on the principle that all flames are less visible in a strong light. On the other hand, a series of experiments made by Dr. Thomas McKeever of England, and published in the "Annals of Philosophy" in 1825, support by their results the popular impression, and these conclusions are referred to by Gmelin in his "Handbook of Chemistry," without questioning their soundness. In these experiments tapers and candles were burned alternately in a dark room and in the sunshine in the open air, the result always being a more rapid combustion in the former. The chemical rays of the solar beam were supposed to interfere with the oxidation of the fuel, and this was confirmed by the apparent greater rapidity with which a taper was made to burn in the red than in the violet extremity of the solar spectrum. In 1857 a paper was read before the American association for the promotion of science, by Prof. J. L. Le Conte, describing a series of experiments recently made by him with the object of further testing this question. In these he adopted the precaution of securing absolute calmness in the atmosphere around the burning body, and of depriving the beam of light of its sensible heat, which might, by rarefying the air, retard combustion. He also by concentrating the rays increased the intensity of the solar light nearly tenfold, with the view of thus exaggerating and rendering more apparent their supposed influence. The cone of sunlight was made to strike upon the flame of a wax candle, counterpoised in a balance, its lower margin illuminating the charred portion of the wick, while the upper boundary of the pencil traversed the flame near its apex. In each experiment the candle was allowed to burn for 10 or 15 minutes, till a steady flame was obtained; and then, as soon as its weight was reduced to that in the opposite scale, a certain quantity (60 or 100 grs.) was removed from this, and the combustion was continued till the equilibrium was again established. Whether in the dark or in the sunlight, no sensible difference was found in the rate of combustion; but this decidedly varied with the conditions of the atmosphere as to barometric pressure and temperature.

COMBUSTION, Spontaneous, the ignition of inflammable bodies without the application of fire, and without obvious cause of increase of temperature. Occurrences of this sort, formerly very mysterious, are now explained by the well understood liability of certain bodies to undergo chemical changes which develop sufficient heat to set them on fire. Recently expressed fixed oils are particularly disposed to oxidize when exposed to light and air. They then absorb oxygen, and give out carbonic acid and hydrogen. If the process goes on rapidly, as it usually does when the oil is diffused through light inflammable substances, as cotton, tow, the waste used for lubricating machinery, oatmeal, &c., the heat may be sufficient to set these on fire. This is the most frequent cause of spontaneous combustion. Cloths saturated with oil, or covered with varnish of oil and turpentine, have thus been inflamed. By being piled together in quantity, the danger is increased by the accumulation of heat. In consequence of the frequent occurrence of cases of spontaneous combustion in "charged silks," or silks that have been treated with grease or oil for the purpose of increasing their weight, the German railways in 1872 refused to receive them for transportation. Bituminous coal lying in large heaps is liable to be ignited by the heat evolved in the decomposition of the sulphuret of iron which it commonly contains. At the mouths of the pits the slates and refuse coal, which contain the most of this mineral, and in which the process of de-

composition is hastened by the heaps being wet with the rains, are often seen in combustion from this cause. The liability to it seriously affects the value of those coals in which pyrites is found in considerable quantity, rendering it hazardous even to transport them by ships. In 1794 a fire occurred from this cause in the royal shipyard in Copenhagen, which consumed 1,600 tons of coal and 1,400 houses. The rapid absorption of water by quicklime is also attended with development of heat sufficient to ignite combustible bodies in contact with the lime. Freshly burned charcoal has the property of absorbing moisture and rapidly condensing it in its pores, generating thereby so much heat that it is set on fire. This often occurs about collieries and in the wagons used for transporting the coal from the woods, and is commonly attributed to the fire not being entirely extinguished in all the pieces of charcoal. Several cases are recorded in the "American Journal of Science" (vol. xlii., 1842, pp. 169 to 195) of combustion occurring in heaps of hard-wood ashes which had long lain undisturbed. The cause not being understood, they were in several instances regarded as cases of spontaneous combustion. It would seem, however, that addition of fresh ashes had been made to the heaps within a few days, or 14 at the most. Still no satisfactory explanation is given of the manner in which a heap of 25 bushels, accumulated during two years previous, could become completely ignited, as occurred in the cellar of President Lord of Dartmouth college; nor how the combustion could commence in the centre of a box of ashes which had received no addition for about two weeks, as described by Dr. J. T. Plummer of Richmond, Ind. Such instances, however they may be explained, exhibit the danger incurred by placing ashes in wooden vessels or in contact with combustible bodies; and the danger would appear to be at all times imminent, though the ashes may have thus remained quietly for two years.—**Human Spontaneous Combustion.** This is now generally believed to be a fiction; but it has been used with great effect by modern temperance lecturers and by novelists. Herman Melville so disposes of an obnoxious character in "Redburn" (1849); and Dickens, in "Bleak House" (1853), made the case of Krook famous, and excited an animated discussion which revived public interest in the subject. But that it has been firmly believed by many eminent medical authorities, and has been a matter of earnest though not entirely satisfactory inquiry by others, will be evident from the citation of the following authorities and cases. Foderé notes an instance which occurred in Lyons in 1644. Devergie, in his *Médecine légale*, records 20 cases, the earliest in 1692, and two thirds of them before the beginning of the present century. The *Dictionnaire de Médecine*, article *Combustion humaine*, cites the opinions of different writers down to the year 1833. Dr. Apjohn, in the "Cyclopædia of Practical Medicine," gives what he considers authentic cases. The fullest information on the subject is in the *Journal de Physique*, in an article by Pierre Aimé Lair, translated and published in "Philosophical Transactions," vol. vi. Among the remarkable cases recorded are the following: Le Cat narrates that while he was lodging in the house of Millet at Rheims, on the morning of Feb. 20, 1725, the body of Mme. Millet, a habitual inebriate, was found at the distance of a foot and a half from the hearth in her kitchen. A part of the head only, with a portion of the lower extremities and a few of the vertebræ, had escaped combustion. A small portion of the floor under the body had been consumed, but a kneading trough and a tub which stood very near were uninjured. Millet was arrested for the murder of his wife, a supposed intrigue with his servant girl furnishing the motive. He was tried and convicted; but on appeal to a superior court he was acquitted on the plea of spontaneous combustion. A more celebrated case, six years later, was that of the countess Cornelia de Baudi Cesenati, of Verona. She was 62 years old, and was accustomed to bathe in camphorated spirits of wine. Retiring one night in good health, the next morning her body was found on the floor, four feet from the bed, a mass of cinders. The walls and furniture of her room, and the walls, shelves, and utensils in an adjoining kitchen, were coated with a moist black soot, and a crust of bread was so contaminated that it was rejected by the cat. Prebendary Giuseppe Bianchini minutely investigated the case, and published an account of it at Verona in 1731, and afterward at Rome. It furnished, as is intimated in the preface to "Bleak House," the precedent for the remarkable death of Krook. "The appearances beyond all rational doubt observed in that case," says Dickens, "are the appearances observed in Mr. Krook's case." The case of Mary Clues first appeared in the "Annual Register" for 1773. She was 50 years old, and was much addicted to intoxication. One night she retired, leaving a lighted candle on a chair near her bed. The next morning her remains were found on the floor between the bed and the chimney. The skin, muscles, and viscera were destroyed; the bones of the cranium, breast, spine, and upper extremities were calcined and covered with a whitish efflorescence; one leg and a thigh were still entire. The room was filled with a very disagreeable vapor; the walls and everything in the room were blackened; but, except the body, nothing exhibited any very strong traces of fire. An almost parallel case is that of Grace Pitt, aged 60, published in the "Transactions of the Royal Society of London" in 1774. Foderé records the remarkable death of Don Gio Maria Bertholi, in 1776. The account is abridged by Paris and Fonblanque in their "Medical Jurisprudence," and the case is one of the best authenticated to be found.

In 1840 the *Bulletin de Thérapeutique* published an account by M. Bubbe-Liévin, surgeon in the army in Algeria in 1839, of the death of a Moor, a habitual drunkard, where the phenomenon was a bluish flame running all over the body, making frightful burns; but the surgeon saw only the results of the combustion, and derived the details from the natives, who probably embellished the facts. In 1839 Dupuytren investigated a supposed case of spontaneous combustion. The victim was an excessively fleshy woman, and addicted to drink; but Dupuytren discovered that she had been sitting over a foot stove filled with burning charcoal, and his theory was as follows: Stupor, due first to alcohol, and heightened by the fumes of the charcoal; the clothes take fire; the epidermis cracks open and streams of melted human fat run out and burn; combustion continues as long as any fragments of cloth saturated with fat remain unconsumed; the room is filled with dense black smoke; and, finally, the victim presents only a mass of charred flesh and bones. The case of the countess of Görlitz, found dead in her chamber, June 13, 1847, excited attention throughout Europe. The upper part of her dress was burned, and her head, neck, and arms were charred. The floor and furniture were much damaged by fire. The physician who examined the remains pronounced the case one of spontaneous combustion. In the year following, Aug. 11, the remains were exhumed, and Liebig and Bischoff, who examined them, published in 1850 their report, exploding the theory of spontaneous combustion. In March of that year Stauff, the count's valet, was tried and convicted for murdering the countess. Subsequently he confessed the crime, and said that the countess having surprised him in an attempt to rob her room, he strangled her, and afterward piled furniture around her body and set it on fire. In 1850 a supposed case had a wide circulation in the French and English journals, and was quoted by Dean in his "Medical Jurisprudence." It was that of a laborer, drinking in a cabaret near the barrière de l'Étoile, Paris. He wagered that he would eat a lighted candle, and had hardly brought it near his mouth when, with a faint cry, he fell lifeless. A bluish flame flickered about his lips, he consumed inwardly, and in half an hour his head and part of his chest were reduced to charcoal. On the publication of this extraordinary case, Liebig at once wrote to Professors Regnault and Pélouze, and to Carlier, the prefect of police, asking for further information. This he immediately received from Carlier, to the effect that the case was wholly imaginary, originating only in the fertile fancy of a sensational journalist. In two cases in England, one in 1854 and the other in 1860, where all the accepted phenomena of spontaneous combustion were present, rigid examination by experts discovered that the victims had been murdered, and an attempt made to burn the bodies to conceal the crime. But in the apparently authenticated cases cited above, as the victims were generally drunkards, the hypothesis has been that their bodies were rendered exceptionally combustible, and for a long while this theory obtained credence. But after a while chemists began to discredit the cases. It was shown that combustion could not occur without an abundant supply of oxygen; that the soft parts of the human body contain 72 per cent. of water, which must be evaporated before consumption by fire can take place; and instances of the extraordinary difficulty of consuming the bodies of persons burned at the stake were adduced. It is noteworthy, too, that nearly all of the supposed authentic cases agree essentially in the following particulars: That the victim is almost always a fat woman, an inebriate, and in some instances addicted to getting up in the night to smoke a pipe, or to sit by the fire; nine out of ten of the supposed cases have occurred in cold weather; and in nearly every case the remains were found near a grate, fireplace, or candle. Dr. Robert Macnish, in his "Anatomy of Drunkenness" (Edinburgh, 1827), says that when "writers like Vicq d'Azyr, Le Cat, Maffei, Jacobæus, Rolli, Bianchini, and Mason and Good, have given their testimony in support of such facts, it requires some effort to believe them unfounded in truth." But he thinks that the witnesses in supposed cases "have been led into an unintentional misrepresentation," and says further: "The subject has never been satisfactorily investigated; and notwithstanding the cases brought forward in support of the doctrine, the general opinion seems to be that the whole is fable, or at least so much involved in obscurity as to afford no just grounds for belief." This was written long before the thorough examinations by Liebig, Bischoff, and other experts, since 1850, whose reports are decidedly adverse to the hypothesis of spontaneous human combustion.

COMEDY. See Drama.

COMENIUS, John Amos, a Czech, whose real name was Komensky, remarkable for his early attempts at reforming education, born at Komna in Moravia, March 28, 1592, died in Holland, Nov. 15, 1671. He studied in Heidelberg and Herborn, and was a teacher in Prerau and Fulneck from 1614 to 1620, when, in the general persecution of Protestants which followed the reverses of the insurgents in Bohemia and Moravia, he lost all his fortune and was expatriated, and for some time lived as a teacher in a retired part of the Bohemian mountains. From 1632 he was pastor of the sect of the Bohemian Brethren at Lissa, then in Poland. In 1641 he was invited to England to reform the schools, in which however he did not succeed, on account of the civil dissensions. At the request of Oxenstiern he now applied himself to the organization of a system for Swedish schools, though residing in Elbing, W.

Prussia. He subsequently repaired to Transylvania, and in 1650 elaborated rules for the Protestant college of Sáros-Patak in Hungary. Returning to Lissa in 1654, he again lost all his books, manuscripts, and fortune by the Polish war of 1657, and spent the latter part of his life in Holland. As a writer in the Czech language he is highly esteemed for his classical style. As a school reformer he was the forerunner of Rousseau, Basedow, and Pestalozzi, suggested a mode of instruction which renders learning attractive by pictures and illustrations, and wrote the first pictorial school book, *Orbis Sensualium Pictus* (Nuremberg, 1658). For instruction in foreign languages he recommended combining with the teaching of the foreign words explanations of the ideas they express. His most celebrated works in this department, *Janua Linguarum Reserrata* (Lissa, 1631), and *Pansophiæ Prodromus* (Lissa, 1639), were translated into many languages.

COMET (Gr. κομήτης, long-haired), a celestial body presenting a nebulous aspect, and travelling under the sun's attraction. Many of these bodies are distinguished by a remarkable tail-like appendage. The greater number of those hitherto known have revolved round the sun on a path whose observed portion belonged to an exceedingly elongated ellipse, or was even parabolic or hyperbolic. A few, however, travel in closed orbits around the sun in known periods. It has been supposed that some among the ancients suspected the periodic motions of the planets; but the only evidence we have on the subject is vague and indefinite. Tycho Brahe was the first to prove by direct observation that comets are not mere phenomena of our own atmosphere, but certainly further away than the moon. Newton, after establishing the theory of gravitation, asserted that comets obey the laws of solar attraction, and therefore move either on elliptic, parabolic, or hyperbolic paths. From observations of the comet of 1680 (commonly called Newton's comet) Dörfel, a clergyman of Saxony, was led to the conclusion that the course of this object was parabolic. But the first real proof of the nature of cometary orbits was afforded by the researches of Halley into the motions of the comet of 1682 (Halley's comet). Halley computed the orbit of this comet, and having found that the figure of the orbit was either parabolic or a very extended ellipse, he examined the records of ancient comets, and after incredible labor succeeded in discovering two whose motions agreed very closely with those of the comet of 1682. One had been observed by Appian in 1531, the other by Kepler in 1607; and Halley noticed that the intervals between the three years 1531, 1607, and 1682 are near enough to equality to suggest that one and the same comet had been observed on all three occasions. Finding that comets were observed in 1305, 1380, and 1456, he was further confirmed in the idea of the periodicity of this comet's returns; and he was thus led to predict the return of the comet about the end of 1758 or the beginning of 1759. He placed the return somewhat later than the former observed intervals would have suggested, because he found that the attraction of Jupiter would retard the comet. When the time for its return approached, many eminent mathematicians recomputed the date of its perihelion passage, and Clairaut announced that this passage would occur between March 13 and May 13, 1759. The event actually took place on March 13, 1759; and it has been shown that a large part of the discrepancy between this date and the mean date of Clairaut's two months would have been removed had Clairaut known of the existence of Uranus, and so taken the disturbing influence of that planet into account. On the next return of the comet in 1835, the epoch of perihelion passage was predicted much more accurately; indeed, the actual event occurred within two or three days of the dates severally announced by Pontécoulant and Rosenberger. The observations of other comets have still further confirmed Newton's theory of cometic motions.—All comets show a *coma* or haze of light. In nearly all cases there is a bright nucleus within this haze, and in a considerable number of instances, but not by any means in all, the comet shows a tail. When a large and complete comet, that is, a comet which possesses a coma, nucleus, and tail, is approaching the sun, the haze of light usually changes from a rounded to an elongated figure. Afterward the comet's light presents a streaky or "combed out" appearance, and then presently a tail is thrown out on the side away from the sun. The tail usually grows longer and brighter as the comet approaches the sun, and continues in existence for some time after the comet has begun to pass away from the sun's neighborhood. But there is a considerable variety in this respect among different comets. Some which have shown beautiful tails as they neared the sun, have reappeared after the perihelion passage with only a short tail or without any tail at all. Others which have shown only insignificant tails while approaching their perihelion, have "reappeared magnified and glorified, throwing out an immense tail and exhibiting every appearance of violent excitement." Most of the comets of short period are tailless or have tails barely discernible. An examination of the drawings prepared for the third volume of the "Annals of the Observatory of Harvard College," to accompany the record of Prof. Bond's observations on Donati's comet of 1858, will teach more respecting the actual processes of change which large comets undergo than any amount of verbal description. It has been justly remarked by Sir John Herschel that these "engravings, in point of exquisite finish and beauty of delineation, leave far behind everything hitherto done in that department of astronomy."—Among the comets most remarkable either for great splendor or enormous real dimensions in recent times

must be mentioned those of 1780, 1807, 1811, 1815, 1819, 1825, 1843, 1847, 1858, and 1861. Among the most remarkable phenomena presented by individual comets we may mention the six tails of the great comet of 1744, and the division of Biela's comet into two distinct comets, each having coma, nucleus, and tail. The latter phenomenon was first observed on Jan. 12, 1846, at the Washington observatory. Three days later European observers noted the same phenomenon. The two comets pursued their course side by side, with singular interchanges of lustre, now one, now the other appearing the brighter. At the return of the comet in 1852 both the comets were still visible in the same telescopic field of view. The perihelion passage of 1859 took place (if at all) under circumstances unfavorable for observation. The return of 1865 should have been readily observable; but the comet was not seen, nor has it since made its appearance. "Can it have come," says Sir John Herschel, "into contact with some asteroid as yet undiscovered, or peradventure plunged into and got bewildered among the rings of meteorites, which astronomers more than suspect?"—The recent discovery of the fact that the November and August meteor systems follow in the track of two comets (the November meteors following the telescopic comet No. I., 1866, and the August meteors following the conspicuous comet of 1862), has led to some interesting speculations respecting the nature of comets and meteors. Schiaparelli, to whom the discovery is in part due, considers the meteors to be dispersed portions of the comet's original substance, that is, of the substance with which the comet entered the solar domain. Thus comets would come to be regarded as consisting of a multitude of relatively minute masses. Others, however, regard comets as chiefly gaseous, and the meteors as due to the solidification of portions of the gaseous coma which have been swept off by the repulsive action which forms the tail. Spectroscopic analysis has thrown some light on cometic structure, though hitherto only faint comets have been subject to careful analysis according to recent methods. Four comets examined by Dr. Huggins of England showed spectra indicative of gaseousness, so far as the nucleus and the brighter part of the coma are concerned. The outer part of the coma seems to shine in part by reflecting solar light. Two of the comets thus examined have shown a spectrum singularly like one of the spectra of carbon. Yet it is difficult to understand how carbon can be present in the form of luminous gas under the conditions actually existing in the case of these comets. The spectroscopic observations by Dr. Huggins on the latest arrival, Encke's comet, have been in all respects confirmed by Prof. Young of Dartmouth college. The motions of Encke's comet, observed on many successive returns, seem to indicate the existence of a resisting medium; but Sir John Herschel has suggested another explanation; and Prof. Asaph Hall has shown in the "American Journal of Science and Arts" for December, 1871, that if resistance is actually in question, such resistance affects Encke's comet in an exceptional manner, for other well known periodic comets show no traces of its effects. All the comets having a period not exceeding seven years travel in the same direction around the sun as the planets, as well as five sixths of those which have periods less than 80 years long. See supplement.

COMFREY (*symphytum officinale*), a plant of the order *borraginaceæ*, a native of Europe, but raised in our gardens. It was formerly imagined to promote the healing of wounds, or even of broken bones, a superstition of which

Comfrey (Symphytum officinale).

traces have remained until the present time. Its virtues are simply those of a demulcent.

COMINES, or **Comynes, Philippe de,** a French statesman and historian, born at the château of Comines, near Lille, in 1445, died at his domain of Argenton in 1509. He stood high in the favor of Charles the Bold of Burgundy, and on occasion of Louis XI.'s imprisonment by Charles at Péronne succeeded in bringing about a treaty of peace between them. In 1472 he forsook the cause of the duke of Burgundy and became councillor and chamberlain of Louis XI., who compensated him so amply for the loss of his property, which had been confiscated by Charles, that he soon became one of the most wealthy and influential noblemen in France. The death of Louis, however, proved fatal to his fortunes. He was no favorite with Anne de Beaujeu, the regent, and was imprisoned on a charge of conspiracy against her. On the accession of Charles VIII. he was again employed in the public service, but went into retirement after the advent of Louis XII., who seemed reluctant to favor him, although he left him in possession of a pension. The fame of Comines rests not only upon his astuteness as a statesman, but still

more upon his *Mémoires*, which give a complete view of the political affairs of his time, and present a vivid picture of the character of Louis XI. They have been frequently printed. Lenglet Dufresnoy's edition (4 vols. 4to, London, 1747) is especially valuable on account of its annotations; but the best and most recent is that published by Mlle. Dupont for the society of French history (3 vols. 8vo, Paris, 1850). Comines figures in Scott's romance of "Quentin Durward."

COMITAN, or **Comitlan,** a town in the state of Chiapas, Mexico, on the river Grijalva, an affluent of the Tabasco, about 40 m. S. E. of San Cristóbal; pop. 10,000. It is well built, and has a fine church and a large Dominican convent, and some trade in cochineal, sugar, and cotton. Its inhabitants are generally in prosperous circumstances, living on the incomes of their haciendas in the neighborhood, which they cultivate by the labor of Indians.

COMITIA, the public assemblies of the Roman people for the transaction of important political business. There were three different kinds of comitia, corresponding to the three great divisions of the Romans: the *comitia curiata*, the *comitia centuriata*, and the *comitia tributa*. The comitia curiata, or assemblies of the *curiæ*, were the original assemblies said to have been instituted by Romulus, and managed all the great concerns of state prior to the establishment of the comitia centuriata. They elected the kings and other chief magistrates, enacted and abrogated laws, and judged capital offenders. After the institution of the comitia centuriata, their prerogatives were gradually abridged, till almost all the great powers which they once exercised were wrested from them, and hardly any remained with them, save those minor ones which they had possessed from the beginning, in common with the higher rights annulled. The comitia curiata were originally called together by the kings, but in republican times generally by some great secular or sacerdotal magistrate. They were composed of those Roman citizens who were members of the curiæ, dwelt within the *pomœrium*, and conformed to the customs and rights of their respective wards. The meetings were not held periodically, but as often as there was business to transact. When the members were assembled, and the omens propitious, the *rogatio*, or matter to be considered, was read, and then each curia, after deciding apart on the question, gave its vote, and the votes of the majority of the curiæ determined the fate of the measure, or, if it was a case of election, that of the candidates. These assemblies were held in that part of the forum called the *comitium*. The comitia centuriata were instituted by Servius Tullius, the sixth king of Rome, with the view apparently of uniting in one body the different sections of the Roman people. Having compelled every man to give in an accurate account of his property, he divided the citizens into six classes, according to their wealth, which he subdivided, according to Dionysius, into 193 centuries. Of these centuries he composed the comitia centuriata, which were held in the Campus Martius, for the election of consuls, censors, and prætors, for the trial of persons accused of what was termed *crimen perduellionis*, or treason, and for the confirmation or rejection of such laws as might be submitted to their consideration. The most usual time of meeting was about the end of July or beginning of August in each year. When the centuries were assembled, they cast lots for priority of suffrage, and the century to which the lot fell voted first, and was styled *centuria prærogativa*. All the others voted in the order of their classes, and as they were summoned, and were thence termed *jure vocatæ*. The presiding magistrate having ordered the prerogative century to be called out to give their suffrages, its members came forward and entered an enclosed space named *septum* or *ovile*, where, if it was a case of election, every man received as many tablets as there were candidates, every tablet having inscribed on it the initial letters of one candidate's name. The *septa* contained numerous large ballot boxes, and into one of these the voter cast that tablet which bore the initials of the name of the candidate whom he favored. If, however, it was a question of the confirmation or rejection of a law, only two tablets were handed to each voter, on one of which were written *U. R.*, the initial letters of *Uti rogas*, "As thou desirest," and on the other *A.*, the first letter of *Antiquo*, "For the old," *i. e.*, the old law (against the new). At each ballot box were stationed certain officers called *custodes*, who took the tablets of every century out of the ballot box, and numbered them by putting a puncture in another tablet for every one deposited. Before the introduction of the ballot system, however, when every citizen voted *viva voce*, an officer called a *rogator*, stationed at the entrance of the septum, asked each individual for his vote. In the election of magistrates, or the confirmation or rejection of laws, equality of suffrages nullified the vote of the century; but in juridical cases equality of suffrages was deemed an acquittal of the accused. The *comitia tributa*, or assemblies of the tribes, were not established till 491 B. C. They were sometimes presided over by the tribunes of the people, sometimes by the consuls or prætors, and were summoned for the election of tribunes, ædiles, quæstors, and other inferior magistrates, for the trial of minor criminals, and for the enactment of special and general statutes. Their place of meeting was not fixed; occasionally they were convened in the Campus Martius, occasionally in the forum, and at times in the circus Flaminius. These were the democratic comitia. Their laws were termed *plebiscita*, or decrees of the plebs, and, unlike the other comitia, they could be called together without the sanction of the senate. Besides these great assem-

blies, there were in the later ages of the republic lesser comitia, termed *comitia calata*, which were held for the election of priests and the regulation of testamentary matters, and in which the people acted only as witnesses.

COMMANDERY, a species of benefice, or an honorary dignity, belonging to certain of the orders of chivalry, and conferred upon aged knights who had rendered worthy services to the order or to the state. The term was first used in the 13th century, and was applied to sums saved from the revenues of the order for the support of warriors fighting against the Mohammedans. It was afterward applied to benefices distant from the residence of the order, and over which a knight was set to collect the revenues. Subsequently, the system of benefices having been abolished with the decline of feudalism, the orders of chivalry preserved the name after they had lost the substance, and conferred the honorary dignity and the title of what had formerly been a revenue. Among the knights of Malta, those to whom commanderies were given were called commanders, and were rather the farmers than the beneficiaries of the order, since they paid a certain rent or tribute to the common treasury. The grand commander was the first dignitary of the order after the grand master. When the religious houses in England were suppressed by Henry VIII. there were more than 50 commanderies in the country. There were commanderies also in the orders of St. Bernard and St. Anthony, and in the Spanish orders of Santiago, of Calatrava, and of Alcántara.

COMMODORE (It. *commendatore*, a commander), a naval officer who usually commands a squadron of ships upon particular service, his own ship being distinguished by a broad pennant worn at the main. In the navy of the United States, by an act of congress of July 16, 1862, a commodore ranks between a rear admiral and a captain; the grade corresponds with that of a brigadier general in the army. Previous to that act commodore was only a title of courtesy in the American navy, captain having been the highest actual rank till 1857, when a law of congress created the title of flag officer for the commander of a squadron.

COMMODUS ANTONINUS, Lucius Aurelius, emperor of Rome, born at Lanuvium, A. D. 161, assassinated Dec. 31, 192. He was the son of Marcus Aurelius and the younger Faustina, daughter of Antoninus Pius. He inherited all the vices of his mother, without any of the virtues of his father, and his advent to the throne in 180 was the signal for a series of cruelties, rivalling if not surpassing those of Caligula and Nero. Hastily making peace with the Quadi and other German tribes, he gave himself up to the vilest debauchery, and even his own sisters became the victims of his lust. Appearing as Hercules before the people, he slew thousands of beasts with bow and spear, and fought publicly as a gladiator many hundred times, while the affairs of the government were left in the hands of the freedmen Perennis, Anterus, Cleander, Lætus, Eclectus, and other worthless favorites. The enormous taxes requisite to support his extravagance, a conflagration of Rome, and a famine, at length drove the people to despair, and disturbances broke out which caused the death of Cleander. Finally, his own favorites, finding that they were marked for execution, resolved upon his death; and the poison administered by his concubine Marcia working too slowly, the gladiator Narcissus was called to strangle him. The senate declared him an enemy of the republic, and commanded his statues to be broken, and his name to be erased from the public inscriptions. Several detected conspiracies, some victories over the Caledonians achieved by Ulpius Marcellus, and the addition of an African corn fleet to that of Egypt, are the principal events of his reign.

COMMON, Rights of, the use for certain purposes of land belonging to another. In the ancient law they were designated as common of pasture, of piscary, of turbary, and of estovers, and this classification is retained by Blackstone; but it lacks precision, for piscary does not belong to lands at all; and again, the right to the use of the water for fishing, &c., is in many cases all the estate that can be claimed by any one, and there are instances where such use is common to all persons without distinction. There is but one case which would come within the definition, and that is common of piscary in inland waters, the land under which is by the common law held to belong to the owner of the soil adjoining the water. This would give such owner the exclusive use of the water, except for navigation, but a prescriptive right may be acquired by another having no interest in the fee. The other rights relate altogether to husbandry, and consist of the right to pasture cattle or other animals belonging to farmers upon lands of another, and to cut turf and wood for necessary fuel and repairs. The common of pasturage is the most important of these, and has been treated of in the books much more fully than the others, but the principles applicable to each are substantially the same. This right is in the old cases held to be appendant, appurtenant, because of vicinage, or in gross. It was appendant when it belonged to arable lands which were originally part of the manor in which the common was claimed, and the commonable right was in such case limited to beasts of the plough, and such as were used for manure. Common appurtenant had no necessary connection of tenure, but might be claimed in other manors than that to which the land whereto the common was appurtenant originally belonged. Nor was it limited to any particular animals, but included every description, as hogs, goats, &c., as well as those which were used in tillage. The difference in origin between these two was that the former grew out of the origi-

nal tenure, and was a general right incident to all smaller estates parcelled out from larger ones, which did not need prescription to sustain; the latter was founded solely upon grant, or upon prescription which always implied a grant. Both continued to exist notwithstanding the alienation of the lands to which the common was appendant or appurtenant, and in case of alienation of part of such lands, the alienee acquired a commonable right in the proportion the lands conveyed bore to the entirety to which the right originally belonged. This equitable principle was adopted to prevent the overcharge of commonable lands by the multiplication of rights from the successive division of estates, so that there could be no increase of the original right; but whatever number of tenants became entitled, they could each have only their proportionate share. Thus the claim of a tenant who by the process of subdivision had become the proprietor of one yard of land, but set up a right of common appendant for the pasturage of 64 sheep (which was the whole right that belonged to the entirety of the original premises), was rejected. (Bennett *v.* Reeve, Willes's Rep., 227.) This case attracted much attention on account of the great amount of learning and ability which it elicited, but the principle had been long before recognized by Coke as applicable both to common appendant and appurtenant. In Wilde's case, 8 Coke's Rep., 156 (Coke being at that time chief justice of the common pleas, in which the case was argued), it was held: 1, that common appendant or appurtenant was apportionable; 2, that the commonable land ought not to be subject to any other or greater charge than originally existed; though the court perhaps erred in assuming as matter of fact that there could be no increase if limited to cattle levant and couchant on the original premises, although the land might have been subsequently divided among several owners; 3, that in case of purchase of a part of the commonable land by a tenant claiming a right of common appendant, the right is diminished in proportion to the land purchased; but in the case of common appurtenant, it would be wholly extinguished by such purchase. And it was said in this case that if alienation was not allowed, all common appurtenant in England would be destroyed, for no land continues in so entire a manner, every acre together with another, as it had been *ab initio*, but for preferment of younger sons, advancement of daughters, payment of debts, &c., part has been severed. In Tyrringham's case, 4 Coke, 36, the origin of common appendant is thus stated: "When a lord enfeoffed another of arable land to hold of him in socage (*per servitium socæ*), as every such tenure at the beginning was, the feoffee should have common of the lord's wastes for his cattle which ploughed and manured his land; because it was *tacite* implied in the feoffment, for the feoffee could not plough and manure the land without cattle, and they could not be kept without pasture. The second reason was for the maintenance and advancement of tillage, so that such common appendant is of common right, and it is not necessary to prescribe therein." In case of the purchase, by the proprietor of the commonable lands, of any part of the lands to which common is appendant or appurtenant, the right is wholly extinguished as to the purchased lands, and the same rule if the whole should be purchased. Unity of possession of the lands to which and the lands in which the common belongs is an extinguishment of the right. It has long been settled that the proprietor of lands in which there is a right of common may enclose and improve part, provided he leave a reasonable amount for common.—Common because of vicinage is when the inhabitants of towns contiguous to each other have intercommoned without hindrance on either side. Yet this is merely permissive so far as to excuse what in strictness is a trespass; but no length of time, according to the opinion of Blackstone, will establish a prescription, but either town may bar out the other.—Common in gross is not attached to lands at all, but merely to the person. This right is not, however, multipled according to the number of a man's heirs. By the English law, if the right descend to several, as in the case of coparceners (*i. e.*, where the descent is to daughters), the eldest shall take, but be liable to contribution. In the United States a different rule is held, viz.: that all the heirs must jointly possess or convey.—The right of common has been comparatively less important in this country than in England; but the principles of the common law have been, with few exceptions, recognized here. It would probably not be admitted in any of the states, not even in those newest settled, that the grant of a piece of land parcel of a larger tract held by the grantor would carry with it common of pasturage or fuel. It can arise only by express grant or by prescription, which, as before mentioned, is always founded upon a supposed grant. The common of estovers, or the right to take wood for fuel, or for other use of the house or farm of the party entitled on the land of another, is held in New York not to be apportionable; so that if partition is made of the premises among several, without reserving the right of common to one, it is gone entirely.—Other somewhat analogous privileges are sometimes spoken of as rights of common; as where the inhabitants of a town or village are permitted to pasture their beasts upon lands owned by the municipality, or in the public highways.

COMMON CARRIER, one who undertakes for compensation to carry goods from place to place for all who see fit to employ him. Of this class are proprietors of stage coaches, owners of vessels, railroad and express companies, and also wagoners and others, who,

either on particular routes or as they may be directed, hold themselves out as carriers for the public indifferently. Persons who thus become general carriers assume peculiar obligations, and are subjected by the law to responsibilities from which mere private carriers, or those who only undertake to carry on particular occasions or for certain persons, are exempt. A common carrier is considered as in a public employment, and he is bound to carry without discrimination for all who may offer to employ him, and is liable for a refusal so to do. His business may be the transportation of all kinds of movable property, or it may be restricted to particular kinds or descriptions; or he may carry movables generally, but exclude particular articles the carriage of which would be peculiarly inconvenient or extra-hazardous to persons or property carried, such for instance as nitro-glycerine; and where the business is thus restricted, the public cannot insist upon an obligation to carry beyond what has been voluntarily assumed. (23 Vermont Rep., 186.) The liability of the carrier is to carry safely, and to deliver within a reasonable time; and he is said in general terms to be an insurer against all loss or damage to the property carried, except such as may occur by the act of God or of the public enemy. A loss by lightning, tempest, the perils of the sea, or any inevitable accident which human care and foresight would not have guarded against, he is not responsible for; but he must respond to the owner for fires occurring by negligence, whether of himself or his servants, or of third persons; for injuries through defects of machinery and vehicles; for losses by collisions, thefts, embezzlements; and for those occurring in consequence of unreasonable delay in carriage or delivery. If, however, he be plundered by the public enemy without his fault, or robbed by pirates, he is excused. But in any case where the carrier relies upon matter of excuse, he will nevertheless be held responsible if his own act or default concurred in producing the injury. (12 Maryland Rep., 9; 30 New York Rep., 630; 41 Penn. State Rep., 378.) A carrier may contract with his employer for a limitation of his common-law liability (6 Howard, 344), and this is very often done by provisions inserted in the bill of lading or other corresponding instrument; but he cannot impose restrictions by his own act merely, and it has accordingly been held that notices posted at his office or other place of business that he would not be responsible beyond a specified amount, or for losses caused by particular perils, were of no force unless it could be shown that they were brought home to the knowledge of the consignor, and that he assented thereto. (19 Wendell, 234, 251.) Notices, however, prescribing reasonable regulations for the conduct of the business, are not regarded as limitations of liability, and the consignor must conform to them, as he must also to the general regulations established by custom, and which, being generally understood, are supposed to be known by every one having transactions which would come within them. A common regulation is one requiring the nature or value of the property offered for carriage to be stated, and limiting the liability of the carrier to the value actually stated, where untruthful information has been given. It is a disputed point how far a common carrier may contract for exemption from responsibility for losses caused by his own negligence. In some cases it has been held that certain new kinds of business from their very nature imposed certain restrictions; as, for instance, the transportation of live cattle, which are always understood to be accompanied by the owner or his servant, whose charge and supervision are inconsistent with the unlimited liability of the carrier as insurer, and must be understood to modify it accordingly. (21 Michigan Rep., 165.) Limitations upon the carrier's liability are sometimes imposed by statute; as in the case of the act of congress of March 3, 1851, which exempts the masters and owners of vessels from liability for losses by fires happening without their design or neglect, and for the loss of certain valuable articles not made known to them and entered truly in the bill of lading.—The character of delivery to be made by the carrier will depend upon the nature and usages of the business and modes of conveyance. A wagon will be expected to deliver at the consignee's place of business; but in the case of goods transported by railroad, the consignee is expected to receive them at the warehouse of the railroad company, unless the company adds to its ordinary business that of draymen also. By some courts it is held that the responsibility of a railroad company as common carriers ceases as soon as the goods are received at the point of destination and placed in their warehouse; while others hold that it continues until the consignee has been notified of the receipt of the goods, and has had reasonable time to take them away; after which time, if they remain in warehouse, the company is no longer insurer, but liable like other warehousemen for negligence. A carrier is entitled of right to demand payment of his charges in advance; but if he does not do so, he has a lien therefor on the goods carried, and also for any advances which may have been made by him in payment of the charges of other carriers over whose lines the goods have come to him. In England, where a railroad company receives goods to be carried over a connecting line and gives receipt accordingly, it is held liable as carrier to the point of ultimate destination (8 Meeson and Welsby, 421); but this doctrine is rejected in America, and it is held liable to the extent of its own route only and for safe and prompt delivery to the next carrier, unless by contract, express or implied, it has assumed a further liability. (6 Hill, 157; 18 Vermont Rep., 140; 22 Conn. Rep., 1.) The responsibility of the carrier begins as soon as the goods

are delivered to him for carriage, unless they are retained for the convenience of the owner, or awaiting his orders.—Common carriers of persons are those who hold themselves out as carriers for hire of such as may offer, and who thereby become bound to carry all who offer. Their undertaking is to furnish suitable vehicles and to carry with reasonable despatch and without negligence. They are not, however, insurers for the safety of their passengers, but are held to the highest degree of care and vigilance, and must supply themselves with the most approved appliances for the conduct of their business. An injury through defect of machinery renders the carrier liable, unless the defect was one which no degree of watchfulness on his part would enable him to detect and guard against. The negligence of the carrier's agent or servant is his own negligence; but he is not liable for the servant's intentional wrongs, except where they are perpetrated in the exercise of an authority which the carrier has conferred, and on his behalf; as, for example, when a railroad conductor thrusts a passenger from the cars to his injury on a wrongful charge of non-payment of fare. (See MASTER AND SERVANT.) Where, however, the injury occurs through the concurring negligence of the carrier and the passenger, the former is not liable, as the law will not undertake to apportion the responsibility in such cases. But if the want of prudent conduct on the part of the passenger is in consequence of fright or alarm caused by the carrier's negligence, he cannot excuse himself on that ground. The common law does not make a carrier liable civilly for a death caused by his negligence; but this has been regarded as a serious defect, and now by Lord Campbell's act (9 and 10 Victoria, ch. 93), and by statutes in the United States, all persons by whose wrongful act, neglect, or default a death is caused, are made liable to the payment of a pecuniary compensation for the benefit of the family or next of kin. An injury to a passenger while he is on the carrier's vehicle in the proper place for carriage is *prima facie* through the carrier's negligence. The carrier may, however, establish reasonable rules and regulations for the management of his business, which passengers must observe at their peril, and may eject from his conveyance any who refuse to comply; and the reasonableness of such rules and regulations is a mixed question of law and fact, except where they are so palpably improper as to be void on their face. Every passenger has a right to take with him reasonable baggage and money for his journey, and for these the carrier is liable as insurer to the same extent as any carrier of goods. What is baggage and what a reasonable amount will depend upon the nature and extent of the journey, and upon the passenger's condition and circumstances in life. Such articles of clothing and personal convenience as are usually taken on going abroad, a watch and common articles of personal ornament, would be included, but not articles taken in connection with the passenger's business, or money beyond what might in prudence be provided for the contingencies of the journey. If, however, the carrier is accustomed to take with his passengers other goods besides their baggage, for a compensation to be paid him, he assumes as to such goods all the responsibilities of a common carrier of goods, and consequently may be liable for a loss thereof, though occasioned by such circumstances as would excuse him from liability to the passenger for a personal injury. The carrier may always demand his compensation in advance; but if he fails to do so, the non-payment prior to an injury will not excuse him from liability.

COMMON LAW. By this term in English jurisprudence is sometimes designated that part of the law of England which has grown up from usage, as distinguished from acts of parliament; the former being also classified as *leges non scriptæ*, the latter as *leges scriptæ*. This last classification is, however, far from accurate; for, as we shall have occasion to show more particularly in another part of this article, the laws were at an early period repeatedly collected and promulgated by royal authority, and in later times have been contained in reported decisions of the courts and treatises of writers upon law; and again, many ancient statutes, the records of which are now lost, were incorporated into the common law, many others of which we have the record being merely declaratory of the common law as it was claimed to have existed before. Such was the *Magna Charta*, as confirmed by parliament, 9 Henry III., the oldest of the statutes of which an original record is now extant; so the statute 25 Edward III., relating to treason, the petition of right, which was passed in 1628, and various other statutes of more modern date, purporting merely to declare the existing law, and not to enact any new provision. The definition of common law above given includes not merely the indigenous customs of the English people, but also so much of the Roman and canon laws as have been introduced in the admiralty and ecclesiastical courts, as well as the rules or maxims which were borrowed by English judges and writers from either of those systems. The term is also sometimes used to express the whole law, statutory or customary, as administered in the most ancient or what was termed common law courts, in distinction from the system of equity as developed in the court of chancery, the latter being of more recent growth, and intended for relief in cases where there was no adequate remedy by the strict rules of the common law. In a still larger sense, it is the common appellation of the entire English law, including even the foreign elements intermingled with it, in distinction from the civil law generally received among European nations, and from the canon law, except so far as adopted in the

ecclesiastical courts of England. It is in the last sense that it is commonly understood in the United States, yet with some modifications, growing out of its limited application under our peculiar political organization. In all the states except Louisiana the common law has been received, but this has been understood not to include statutes, except so far as they had by their antiquity become merged in the common law, or had been recognized by colonial legislation or by general usage. The general course has been to reënact the English statutes which it was deemed important to retain. In some of the states, however, many of the statutes have been admitted as having acquired legal validity without such reënactment. The ecclesiastical administration of law is also excluded, but this has been chiefly by a statutory establishment of courts in which the ecclesiastical has been united with civil jurisdiction. The principles of the canon law, with that exception, have remained in force in this country so far as they had become part of the common law.—In the exposition of the subject it will be proper to consider it in a twofold aspect, viz.: the development of the common law from its primary sources, and the peculiar principles by which it is distinguishable from other systems of law. The first branch of our inquiry is deeply interesting, as containing the true history of the English people, and thus illustrating the chief element of our own nationality. No other modern European nation has produced for itself an entire system of law. The Roman is the basis of all continental jurisprudence, and in some countries, as Italy and some of the German states, is still in full force as an original authority, modified only by political changes and local usages, which, however, have a similar relation and as limited a proportion to the original as the statutory has to the common law in England. In other countries, as Spain, it has been digested in common with the modern additions, but this does not supersede a reference to the original source for the resolution of any difficult questions; and lastly, in other countries, as France, Prussia, and Austria, it has been reconstructed into the form of a code, though it still furnishes the elementary principles, legal language, modes of reasoning, and in general the forms of proceedings of all these compilations. On the other hand, whatever foreign element may have been intermingled with the English law has been assimilated by a process that may be compared to chylification in the animal system. The primitive constituent of this law may be safely assumed to be the Saxon. Nothing can be traced from the Britons, either of local usages or of the Roman law as administered while they were subject to the imperial government. Whatever has been derived from the latter source was introduced long afterward, and chiefly through the Normans. The very language which we may suppose to have been spoken by the common people when Britain was a Roman province was lost, or is to be traced only in Wales and Brittany. Sir John Fortescue, who wrote in the reign of Henry VI., in his zeal to magnify the common above the civil law, maintained that the former was the more ancient, for that the customs upon which it was founded had existed from the earliest period, without interruption by the Roman, Saxon, Danish, and Norman conquests; and Selden, in his notes upon Fortescue, does not dispute the assertion, further than that he says customs were also introduced by the Saxons, Danes, &c. Coke also asserts that the common laws of England were of greater antiquity than any other human laws (Pref. 2d Reports), and quotes the opinion of Fortescue at full length (Pref. 6th Rep.). This extravagant hypothesis is worthy of mention only as an illustration of the singular partiality of the English mind for whatever was of native origin, and the prejudice existing at every period against whatever was of foreign growth. In estimating the proportion that Saxon usages contributed in the formation of English law, it would be too limited a view if we should take into account only the records now extant of particular laws and forms of proceedings. These records are imperfect, and even if we had the entire body of laws so far as they were ever reduced to writing, it would furnish but a part of what then existed and was perpetuated, and again it would be leaving out the self-developing power inherent in the habits of the people. The nation continued to be essentially Saxon even after the Norman conquest. The tenure of real estate was indeed radically changed by the introduction of the feudal laws, yet with steady perseverance the middle class gradually obtained amelioration of that system, and ingrafted upon it many peculiar rules and forms congenial with the national character. So the Norman sovereigns undertook to revolutionize the whole judicial administration. The *aula regis*, consisting of the king and council, sought to convoke to itself the judicial business, which had before been chiefly transacted in the Saxon county courts, presided over by a sheriff and bishop. The Norman language was introduced as the law language at least of the *aula regis*, and of the superior courts into which that tribunal was subsequently resolved, and Norman lawyers and judges sought to introduce the forms of practice and even rules of decision to which they had been accustomed. Yet in spite of these disadvantages, Saxon customs still maintained their hold of the people. Terms were invented in Norman phraseology to express many of the judicial proceedings. The pleadings were indeed in Latin, but trials were conducted and decisions reported in the Norman. But underlying these exterior forms can be seen the same principles of right which constitute the earlier law of the country, and the administration of justice was still in fact practically in accordance with Saxon

usages. This may be attributed in a considerable degree to the large amount of business which continued to be transacted in the county courts, where the Saxon language and usages were strictly adhered to. The appointment of itinerant justices to go into the several counties of the kingdom for the trial of civil and criminal causes, which became a fixed custom in the reign of Henry II., must have also contributed largely to the perpetuation of provincial forms. Hence it may be justly said that the laws continued to be formed as new cases arose, by the same habit of mind after the conquest as before, and that the common law continued to be developed from the Saxon original even under the Norman sovereigns. Of the collections of Saxon laws there are mentioned: 1. The *Dom Bok* or *Liber Judicialis* of Alfred the Great, which was designed as a code for the government of the whole kingdom, and is supposed to have consisted of the local customs of different parts of the country, viz.: *a*, the Mercian laws, which prevailed in the counties bordering on Wales, and which may have retained some of the old British customs; *b*, the West Saxon, which appertained to the southern and southwestern counties; *c*, the Danish, which had been introduced on the eastern coast, where the Danes had settled. It appears that some laws were taken from the Old Testament, and it is likely that Alfred may have taken some liberty with existing regulations, particularly with the penal laws, as by a new enactment making murder a capital offence. But whatever was not in accordance with the spirit of the people came very little into use, and the whole was much interfered with by wars and consequent civil disorders. It has been said by some writers (Blackstone and others) that this code was extant as late as the reign of Edward IV., but it is now lost. Hallam, however, questions the authenticity of the work referred to. 2. The compilation of Edward the Confessor, the basis of which was the previous code of Alfred, and was intended to be a complete collection of laws both customary and statute. This obtained great celebrity, being the system which was in force immediately prior to the conquest, and consequently identified by the Saxons with their nationality. When therefore they often demanded of the Norman kings confirmation of the laws of the confessor, they meant only the guarantee of the laws by which they had been formerly governed. This compilation is also lost. In some old writers there is a reference to a compilation begun by King Edgar, grandfather of the confessor, but this is supposed to be the same that was afterward completed by the latter. 3. A collection of ancient Saxon laws, canons, decrees of councils, and other public acts, was made by Lambard in the reign of Elizabeth, under the title of *Αρχαιονόμια, sive de Priscis Anglorum Legibus.* These laws are in Anglo-Saxon, and among them are some of Ethelbert, king of Kent (about 560). To this collection additions have been since made by Dr. Wilkins.—The extent of the change of the laws made by the Normans has been the subject of much debate. It was chiefly in the tenure of real estate and the incidents resulting therefrom. On the one hand, it has been maintained by Coke, Selden, and others, that the feudal tenure existed among the Saxons before the conquest, but by Hale, and especially by Sir Martin Wright, that it was first introduced by the Normans. Without entering upon that discussion, it will be sufficient here to say that principles relating to real estate are apparent soon after the conquest, radically differing from those recognized by the Saxons before that time. Among these may be specified, that landed property according to the Saxon laws was hereditary, that, with some exceptions, it descended to all the sons, and that it could be aliened, mortgaged, or devised at the pleasure of the owner; whereas, not long after the accession of the Norman sovereigns, we find the descent of lands to the heir depending, at least in theory, upon the consent of the superior lord, as shown by the exaction of a compensation, called a relief, which the heir was compelled to pay; that the land descended to the eldest son, in exclusion of the others, and during the infancy of the heir the seignior or lord had the custody of his person and the care of his estate; the land could not be aliened nor mortgaged, nor devised without the consent of the lord, nor sold under judgment for the payment of debts. Some of these restraints were relaxed in no long period afterward, as by a law of Henry I., which allowed a man to alien lands he had himself acquired, and which had not come to him by descent; this was modified in the reign of Henry II. by allowing alienation of purchased lands if he had other lands by descent sufficient to provide for his children, and if he had not, then he could only alien a part. So likewise in the reign of Henry II. alienation of a part of the inheritance was allowed upon the same conditions. But disposal of lands by devise was never allowed until the reign of Henry VIII., when the statute relating to wills was passed. In the system of judicature, among other changes was one which at the time was perhaps not designed to affect the mode of administering the laws, but which became the occasion of a vast extension of the jurisdiction of ecclesiastical courts and the bringing in of a foreign canonical law. This was an ordinance of William the Conqueror, by which the bishop, who had formerly sat in the county courts with the sheriff (the two together disposing of all causes, civil and ecclesiastical), was directed to hold a separate court for the trial of ecclesiastical cases. The bishops, being thus made independent of the secular courts, proceeded to appropriate to their separate jurisdiction a large number of cases, under pretence of their

involving something of a spiritual nature, as tithes and benefices. So they claimed exclusive cognizance of all questions relating to marriage, on the ground that it was a spiritual contract, and this claim involved not merely the power of annulling marriages and granting divorces, but also of determining questions of legitimacy and bastardy. The probate of testaments, it appears, had previously belonged to them, and this carried with it the cognizance of legacies. Thus, for a considerable time, any questions relating to either, when incidentally involved in a civil court, were referred to the ecclesiastical court for an answer to the particular question, when the civil court proceeded with the determination of the case. Jurisdiction of the estates (that is to say, the personal effects) of persons dying intestate was obtained under a custom which is spoken of in a law of Henry I., that such effects were to be disposed of *pro anima sua*. This custom must have grown up after the conquest, for by the Saxon laws both real and personal estate descended in the same manner in case of intestacy. What would be most for the benefit of the soul of the intestate, it was maintained, the bishops were most competent to decide. In King John's charter (the original Magna Charta) it was expressly provided that the chattels of an intestate should be disposed of by the next of kin *per visum ecclesiæ*. This clause, though it is said to have been also contained in the charter of Henry III., was left out in the exemplification on the roll, 25 Edward I., from which the Magna Charta was copied in the statute books. Under this it became an admitted right of the ecclesiastical courts to issue letters of administration in cases of intestacy. The law to which ecclesiastical courts had been formerly subject had been first established by a national synod held in 670, and was called the *codex canonum vetus ecclesiæ Romanæ*. Various laws were passed after that time for the regulation of ecclesiastical matters, all of which, together with the original code, were reviewed by William the Conqueror with the assent of his great council. There was, therefore, a national canon law which had been prescribed or sanctioned by the legislature, and which did not depend upon pontifical authority. Under the new constitution of ecclesiastical courts, the clergy now, however, sought to introduce the entire canon law as promulgated at Rome. A compilation by Ivo de Chartres, in the reign of Henry I., contained many innovations upon the ancient law; but after the digest of the whole pontifical canon law by Gratian had been adopted at Rome, it became a favorite object with the English clergy to procure its recognition as the basis of their ecclesiastical law. As this compilation was derived chiefly from the Roman or civil law, the latter was also regarded with much favor by ecclesiastics, and they introduced public instruction at Oxford upon both the canon and civil law. Such, however, was the national jealousy, that in 1152 the king prohibited the reading of books of canon law, referring, it may be presumed, to the two compilations by Ivo de Chartres and Gratian. The doctrines of this foreign canon law being in many respects subversive of the authority previously exercised by the civil government over the ecclesiastical courts, a struggle took place in which the whole pontifical power was brought to bear in their favor. The constitutions of Clarendon, which were enacted by Henry II. with the assent of the great council, in 1164, and confirmed at a council held at Northampton in 1176, were intended as a final settlement of the disputed points. By these it was determined that questions concerning benefices (that is to say, the right of presentation) should be tried by the king's secular courts; that ecclesiastics should be bound to come into the king's courts to answer to any matters cognizable there; that there should be no appeal from the archbishop's court except to the king in person; questions in relation to benefices, when the matter involved was whether the benefice were lay or eleemosynary, were to be determined in the king's court by a recognition of 12 men (a jury); lastly, the ecclesiastical courts were excluded from jurisdiction of pleas of debt, which they had lately assumed upon pretence that they were due *fide interposita*. In consequence of the king's remorse for the murder of Becket, these constitutions were not strictly executed during the rest of his reign, but they were not repealed.—It would exceed our limits to trace further the history of the ecclesiastical laws of England. It will be sufficient to say that by various legatine and provincial constitutions, the former being enacted by national synods, the latter by provincial synods, held either by the archbishop of Canterbury or of York, the canon law has been settled with sole reference to the exigencies of the church and kingdom of England, and its authority now rests upon a statute of Henry VIII., by which it was declared that all canons, constitutions, &c., then existing, and which were not repugnant to the law of the land or the king's prerogative, should remain in use. An incidental effect of the enlargement of ecclesiastical jurisdiction was that the civil law was referred to for the decision of many questions, and the rules thus adopted were of course recognized by other courts; but in addition to this, the law of England relating to personal property, which was comparatively deficient, received a large accession from the civil law, with which the judges had now become somewhat acquainted. The rules of consanguinity and therefore of descent, except the law of primogeniture, were taken wholly from the canon law, which in this particular differed from the civil. And even as to primogeniture, there was for a time an alternation between the feudal principle, which gave to the eldest son the entire inheritance, and the

Jewish or canonical rule, which allowed a double portion to the eldest, but gave to the others also a share of the estate. Thus in the reign of Henry I. it appears that the eldest son took only the *primum patris fœdum* (the principal manor), the rest being left to descend to the other sons; but this rule was of short duration, for in the reign of Henry II. the eldest son was considered the sole heir of the whole inheritance. This related to lands held by military tenure or knight's service; socage lands (which were held by other services, and finally for a mere pecuniary compensation), even as late as the reign of Henry II., descended to all the sons, but the eldest was entitled to the capital messuage. This was not, however, universal. The doctrine of representation was not entirely settled, and Glanville (who wrote in that reign) says that it was a question, when a man left a younger son, and a grandson by an elder son, which should succeed; and he expresses the opinion that if the elder son had been provided for by an appointment of land during his life, the grandson should have no claim against the uncle for the remainder, though perhaps the eldest son might himself have done so had he survived. Gradually, however, all lands became subject to the strict feudal rule of primogeniture, except in certain places, where, by special custom which had been unbroken, it was otherwise.—As to personal property and contracts, how extensively the rules of the civil law were adopted may be seen in the treatise of Bracton, *De Legibus et Consuetudinibus Angliæ*, which was published in the reign of Henry III. The arrangement of the subject is similar to that of Justinian's Institutes, and many principles are extracted from the Pandects, sometimes in the very language of the original. But Bracton was no servile copyist. He had a great legal mind, and he selected and applied the rules of law, from whatever sources derived, with much discrimination, and defined and explained them with precision. Such was his adaptation of legal principles to the peculiar circumstances and habits of the English people, that it was not understood by his contemporaries how largely he had drawn upon the civil law. During a long period, down even to the time of Coke, he held much the same relation to the common law that in later times Pothier had to the French law, with only this difference, that Bracton was also profoundly versed in the practice of the courts and forms of proceeding.—As our object is simply to develop the primitive sources of the common law, and the general principle or process of its formation, it will be unnecessary to trace minutely the successive changes, from its earlier form to the later and more complicated system. It will be sufficient to refer summarily to some of the important incidents. 1. The relaxation of the feudal principle of nonalienation, until all restriction was removed by the statute *Quia emptores*, 18 Edward I., and other acts; then the introduction of conditional fees, or estates tail, which, by the statute *De Donis*, 13 Edward I., were restricted from alienation, and the evasion of the statute by new forms of conveyance, viz., fines and common recoveries. 2. The prohibition of conveyances to religious houses and persons. This was first by the Magna Charta of Henry III., which was construed to relate to religious houses only; and in consequence the act *De Religiosis*, 7 Edward I., commonly called the statute of mortmain, was passed, by which the prohibition was extended to all persons holding for similar purposes; and in the statute *Quia emptores*, above referred to, which gave general liberty of alienating lands, a proviso was inserted that this should not authorize any kind of alienation in mortmain. Common recoveries were resorted to by the ecclesiastics to avoid the effect of these disabling statutes; but this device was checked by statute 13 Edward I., which provided that the fiction should be disregarded, and the real right should be tried, and if not found in the religious corporation, the land should be forfeited. Next the ingenuity of the clergy devised a form of conveyance, by which, instead of the fee, the use only was given to the religious beneficiary, while the seisin remained in a nominal feoffee; and courts of equity, which were then under the direction of the clergy, held that the feoffee was bound in conscience to account to the *cestuy que use* for the profits of the estate. This device was, however, defeated by the act 15 Richard II., which enacted that uses should be subject to the statutes of mortmain as well as the lands. When the statute relating to wills, 32 Henry VIII., was passed, devises to corporations were excluded. By a subsequent act, 43 Elizabeth, a devise to a corporation for a charitable use was allowed, and this is now the sole right which religious corporations have for the acquisition of real estate either by deed or will. 3. The introduction of uses, as before mentioned, gave rise to a complicated part of the English law of real property. Great landed proprietors, for the purpose of perpetuating estates in their families, and to prevent alienation, resorted to the expedient which had been invented by the clergy, of conveying the use instead of the fee, and in the court of chancery such conveyance was held binding for any length of time. This gave rise to the statute of uses, 27 Henry VIII., by which the use was transferred into possession, or in other words, the estate vested in the *cestuy que use*. By a narrow construction of the act, its operation was to a great extent evaded by the substitution of trusts for uses, and under that denomination conveyances have been introduced which are enforced in chancery, but with some important modifications in regard to their legal effect. (See BARGAIN AND SALE.) 4. The various provisions of law in relation to personal liberty and rights. This is perhaps the most important part of the common law, but it would greatly exceed our limits to attempt to give even a summary of its

history. A multitude of statutes were passed, at various periods, declaratory of the common law, or in aid of what was claimed as constitutional rights, the most important of which were the Magna Charta of King John, confirmed by Henry III.; the petition of right, passed in the reign of Charles I.; the *habeas corpus* act, in that of Charles II.; the bill of rights, in that of William and Mary; and the act of settlement under William III.—Three subjects remain to be considered, viz.: chancery, admiralty, and the modern commercial law. As to the equity law as administered in the court of chancery, see CHANCERY. The courts of admiralty have jurisdiction of maritime causes, which were considered to be out of the reach of the ordinary courts of justice. It was a peculiarity of the common law that every action was considered local, and was triable in a particular county. Hence causes of action which arose at sea, or in foreign ports, whether upon contracts or for injuries, could have no venue in any county in England. The objection in cases of contracts or injuries in foreign places has been obviated in later times by a fiction which represents the transaction to have taken place in an English county, and the common law courts have taken jurisdiction of that class of cases, with the exception only of what are purely maritime in their nature, which have been left exclusively to the admiralty. The proceedings in these courts are analogous to those of the civil law, yet not directly or entirely derived therefrom. The maritime laws of other countries are referred to, as well in respect to rules of decision as to the mode of proceeding, yet not as binding authority; for the law of England recognizes no foreign law as such. Common usage limited by divers acts of parliament has, however, admitted to a certain extent the principles contained in maritime codes, especially the Rhodian laws and laws of Oléron. The modern English commercial law has grown up chiefly within the last 200 years, and has attained its present complete state by the mere development of principles recognized by the common law. It is a memorable instance of the expansive power of law from natural resources. Statutes have had but little to do with it. The civil law, and the modern codes or systems founded thereon, have been no otherwise availed of by English judges than to aid their own reasoning. Lord Mansfield and other eminent judges were familiar with foreign jurisprudence, but they were able to decide commercial questions by a process of reasoning entirely congenial with the common law.—The second inquiry which was proposed at the beginning of this article was a summary of the peculiar principles by which the common law is distinguishable from other systems of law. 1. Security for life, liberty, and property. We have already referred to the declaratory statutes by which personal rights are guaranteed. But it would be a mistake to suppose that these statutory provisions have constituted the real defence of English liberty. They are in fact but the expression of the stern, indomitable spirit of independence which has been the honorable distinction of the national character, and without which no charter or statutes could have availed anything against arbitrary power. The statutes themselves at an early period were in fact too general in their terms to have furnished any sure protection against corrupt judicial construction by subservient courts, had it not been for the constantly renewed exhibition of persistent public feeling which could not be safely trifled with. The famous clause in the Magna Charta, which has been often called the foundation of civil freedom in England, was in these words: *Nullus liber homo capiatur vel imprisonetur, aut disseisiatur de libero tenemento suo, vel libertatibus vel liberis consuetudinibus suis, aut utlagetur aut exulet, aut aliquo modo destruatur, nec super eum ibimus nec super eum mittemus, nisi per legale judicium parium suorum vel per legem terræ. Nulli vendemus, nulli negabimus, aut differemus rectum vel justitiam.* (No free man shall be arrested, or imprisoned, or disseised of his freehold, or disfranchised of his liberties or customary rights, nor be outlawed or expelled from the country, or in any other manner destroyed, except by the judgment of his peers or by the law of the land. We will sell justice to no one, nor deny it to any, nor delay its due administration.) These are energetic expressions, yet of what avail would they have been against a tyrannical Henry VIII., who would have held, as he did in some instances, that his own will was the law of the land, or a faithless Charles I., who could assent to the petition of right and evade its effect by falsifying the record, if the liberties of the commoners had depended upon a mere charter? Some of the later statutes are more specific in their provisions. The petition of right required the cause of arrest to be specified in the warrant under which any man was imprisoned. The *habeas corpus* act further provided for a determination of the sufficiency of the cause of arrest, and a discharge if such arrest should be found to be illegal. Other acts provided against the exaction of bail for an excessive amount, in cases where the arrest was lawful. It is to be remembered that all these and many similar statutes purported only to guard against encroachments upon rights claimed to exist by common law. It has always been customary in the United States to incorporate in the constitutions of the several states, or to declare by statutes, some of the most important of the personal rights which have been the subject of controversy in England. There is, however, but little occasion for such reënactment. The privileges thus declared are inherent in the very structure of our society, and recognized by our common legislation. Our danger does not lie in that direction, but rather in too unchecked license. The Athenian state would, perhaps, furnish us a more apt precedent of

the evils to which we are exposed, and the appropriate counteraction. 2. Trial by jury has been the most noticed of common law rights, because it belongs exclusively to the English, having been admitted in no other country until within a very recent period. It has been attended with doubtful success in France and some other states where the French code has been introduced either as law or precedent. Sir John Fortescue insisted that this mode of trial had not been introduced in other countries because a class of men could not be found there fitted to serve on juries. "For though there be in them men of great power and of great riches and possessions, yet they dwell not nigh one to another, as such great men do in England; neither so many inheritors and possessors of land are elsewhere as in England." (Fortes. *De Laud. Ang.*, c. 29.) The meaning of this is, that in his time there was no middle class of men between the nobility and the impoverished peasantry; and it was undoubtedly true that no country in Europe then had a common people as well provided and intelligent as the English. But although at the present time there may not be the same difference that then there was, between England and other countries, in the comforts of the commonalty, yet it is equally true in our time that there is a comparative deficiency of qualification still existing in continental countries for that office. It requires a training for many successive generations to fit men for judicial functions; it requires above all an individual independence, which has been peculiarly the characteristic of the English people. Possession of a competence is also important. It is related by the old writers that during a considerable period after the conquest, when the common people were oppressed and impoverished, it was difficult to maintain the Saxon administration of justice in the county courts, by reason of the lapsed integrity of the freeholders, who were usually assembled in those courts as jurymen. This led to a proceeding called an attaint, by which a jury was put upon trial for a false verdict, and a severe penalty followed conviction. The English character afterward improved, however, and the trial by jury has always been maintained in a great degree of purity. 3. The mode of proof in trials. The English law of evidence is an extensive branch of the law, and has been founded upon good sense. In criminal cases, the accused parties are not compelled to testify against themselves; and although, upon preliminary examination before magistrates, the accused is permitted to make his statement, he is not compelled to do so. Much less was it ever permitted in England, except for a short period under the Tudors and the first Stuart, to put a man to torture to extort his confession. This is mentioned by Fortescue as one superiority of the English laws, from which it may be inferred that the practice did not then exist, though the introduction of the rack is referred by Coke to the duke of Exeter, in the reign of Henry VI. It was not used in England after the reign of James I. 4. The rules of the common law relative to husband and wife cannot challenge the merit of superiority to the corresponding law in other countries. The personal property of the wife became the husband's so far as he could get possession; and it was with extreme difficulty, and only by the aid of the court of chancery, that she could formerly be protected in the enjoyment of any part of her property. The law has within a recent period, and especially in the United States, been ameliorated in favor of the wife, but this change has been by statute and not by any self-amelioration of the common law. Marriage can be dissolved only for one offence committed after the marriage, viz., adultery. For some preëxisting causes, as impotence, fraud, &c., the contract may be declared null; but no subsequent cause but the one above mentioned is a ground of divorce. Under the same head we may mention the steady persistence in the ancient doctrine that a child born before the marriage is illegitimate. There has always been a special prejudice against any change of the law in this respect, perhaps at an early period, owing to the general opposition to the canon law. *Nolumus leges Angliæ mutari quæ hucusque usitatæ sunt et approbatæ*, said the barons when it was proposed in the reign of Henry III. to legitimate children born before marriage. Fortescue praises the good sense of the rule of the common law, and Blackstone maintains the same view. It is enough for our present purpose to say that in that respect it differs from the laws of most other countries. 5. The English law of descent, including primogeniture, is another peculiarity which has been already sufficiently noticed. 6. Passing over many other points of lesser consideration, the last and principal circumstance distinguishing the common law is the mode in which it has been promulgated. This has been by the decisions of courts. Treatises of writers have no authority, except as sustained by decisions. It was thought as early as the time of Bacon that the decisions had become so numerous that they needed to be digested, and digests were in fact prepared, though not by public authority. Still the cases have gone on accumulating; abridgments and digests have followed; the older books are no longer cited, but the rules and reasons have been reproduced in other forms. The law seems to be still in growth, while the richness of our legal learning is the detritus from ancient tributaries, the sources of which we can no longer trace with distinctness.

COMMON PRAYER, Book of, the formulary of public worship of churches of the Anglican communion. The early British church appears to have adopted, many years previous to the departure of the Romans from Britain, a liturgy almost identical with that of the Gallican churches, and which, like the latter, was

derived from the Ephesine liturgy of St. John. To this the remnant of native Christians in the west and southwest, who had escaped the fury of the Saxon invaders, clung with great tenacity, and Augustin upon his arrival in England in 596, on his mission to convert the Saxons, found it in common use wherever Christian worship was tolerated. Being desirous of establishing the Roman ritual, to which the British bishops strongly objected, he applied for instructions to Pope Gregory the Great, who authorized him to choose either the Gallican or the Roman services, or selections from various forms, as he might find most suitable. The result was a species of amalgamation of liturgies. Different dioceses or districts adopted different modifications of the forms of public worship, in all of which, however, the influence of the early English liturgy was more or less perceptible. After the Norman conquest a vigorous effort was made to secure uniformity in the performance of divine service, and about 1085 Osmond, bishop of Salisbury, compiled the "Sarum Use," or prayer book of the diocese of Salisbury, which eventually became the principal devotional rule of the Anglican church for nearly four centuries and a half. Other local uses, however, prevailed, such as those of Bangor, Hereford, York, and Lincoln; and the Roman system was recognized in most of the monasteries. The service books of the several English uses were in the Latin language; but long before the period of the reformation books of private devotion in the vernacular, called "Prymers," had been introduced, of which three, containing the Lord's prayer, the creed, the ten commandments, and other offices of worship, were put forth between 1535 and 1545. Early in the reign of Henry VIII. amended editions of the Salisbury breviary and missal appeared, and subsequent to 1538 many editions of the Epistles and Gospels in English were published. In 1544 the litany was translated, with the omission of the names of saints which had accumulated in the Latin litanies. These publications were but the preliminary steps toward the introduction of a reformed prayer book. In 1542 a committee of convocation was appointed, with the sanction of Henry VIII., to consider what revision should be made in the existing service books. The committee sat for several years, and during the life of Henry were compelled to act with extreme caution, as the "statute of six articles," passed through his personal influence, made their labors penal. After his death in 1547 their number was enlarged, and, the obnoxious statute having been repealed, they produced at the close of the year "a form of a certain ordinance for the receiving of the body of our Lord in both kinds, viz., of bread and wine," which was ratified by parliament in March, 1548, and was authorized to be used until the whole of the projected service book should be prepared. In the following December they laid before parliament a reformed book of common prayer, which, together with an "act for uniformity of service," was adopted by that body in January, 1549, and came into general use on Whitsunday, June 9. This book, known as the first service book of Edward VI., was the result of six years of diligent labor on the part of the revisers, who endeavored to reduce the different uses prevalent in England to one, the reformed Salisbury use of 1516 and 1541 forming their basis, and to make their work simple and intelligible. They translated into English from the existing service books the prayers, psalms, hymns, epistles, and gospels, omitting what appeared to them to have been derived from other sources than Scripture or primitive practice, and expunging, especially from the communion service, the prayers of invocation to the Virgin Mary and the saints. Where new elements of thought are visible, the sources which supplied them were the reformed breviary of Cardinal Quignones, recommended by Pope Paul III., and especially the "Consultation" of Hermann, archbishop of Cologne, compiled in 1543 with the aid of Bucer and Melanchthon. To the latter formulary the baptismal office was largely indebted, and through it to one of Luther's compilations, made as early as 1523. The new book comprised the order for matins and even song, corresponding with morning prayer and evening prayer in the modernized prayer book, and which were a condensation of the "seven hours of prayer" in the breviary; the introits, collects, epistles, and gospels used at the celebration of the holy communion; the office of the communion; the litany; the rite of baptism; confirmation, which included the catechism; matrimony; the visitation and communion of the sick; the burial of the dead; the purification of women; and a form of service for Ash Wednesday. The psalms appointed to be sung at matins and even song were taken from the "Great English Bible" of Cranmer, and this version is used in the "Book of Common Prayer" to the present day in preference to that contained in the authorized version of the Scriptures. This service book did not require absolute uniformity in outward observances, but allowed the practice in minor details of public worship to be guided by individual tastes and preferences. But a statute passed both houses of parliament in January, 1549, enjoining under the severest penalties that after the feast of Pentecost following, all ministers of the church within the realm of England should be bound to use the form of the said book and no other. In 1550 a "Form for the Ordering of Bishops, Priests, and Deacons" was drawn up, which was subsequently incorporated with the prayer book.—Scarcely had the new book come into use when it encountered opposition from the more radical school of reformers, headed by Hooper, bishop of Gloucester, and several continental Protes-

tants, of whom the most eminent were Peter Martyr, Martin Bucer, and John à Lasco, who had come to England after the accession of Edward VI., and made their way to important posts. Calvin also urged upon the protector Somerset the necessity of pushing the reformation in England further than it had gone. The court yielded to these influences, and the young king declared himself in favor of a more thorough revision of the prayer book. Cranmer, archbishop of Canterbury, one of the framers of the first book, was induced to give his consent to the undertaking, and another committee of divines, who are conjectured to have been the same who prepared the ordinal of 1550, undertook the preparation of a second prayer book, which was duly ratified by parliament, and came into use on All Saints' day, 1552. This is substantially the "Book of Common Prayer" in use at the present day. The difference between this book and that of 1549 consists chiefly in the following particulars: To the offices of matins and even song, which began with the Lord's prayer, were prefixed the sentences, exhortations, confession, and absolution. In the communion service the ten commandments were added, the title of the prayer "for the whole state of Christ's church" was changed to that of a prayer "for the whole state of Christ's church militant here on earth," and the commendation of the departed to divine mercy was omitted. In the prayer of consecration the invocation of the Holy Spirit to sanctify the elements was omitted, and in the administration of the elements a different form of words was used. In the office of baptism the practices of exorcism, anointing, putting on the chrisome, and trine immersion, prescribed in the first book, were abolished in the second. In the burial service the prayers for the dead were changed into thanksgiving, and the service for Ash Wednesday was entitled "A Commination against Sinners." Certain changes were also made in the vestments of the clergy. A few months after this book came into use Edward VI. died, and the first parliament of his successor, Mary, by an act passed in October, 1553, restored the services to the condition in which they were in the last year of Henry VIII. In November, 1558, Elizabeth succeeded to the throne; and early in April, 1559, the second book of Edward VI. was restored to use, with certain slight modifications, prominent among which was the omission of the litany clause, "from the tyranny of the bishop of Rome, and all his detestable enormities." The "ornaments" of the church and the ministers which had been in use under the first book of Edward VI., but had been curtailed by the second, were also restored. The prayer book thus modified, of which a Latin version was also published, was at length acquiesced in by the great body of the English people, and, according to Sir Edward Coke, was even approved by Pope Pius IV., who offered to give it his full sanction "so as her majesty would acknowledge to receive it from the pope, and by his allowance." This statement of Coke's, however, is not accepted as authentic by Catholic authorities. With the exception of a revision of the calendar, no further changes were made in the prayer book until the accession of James I. in 1603. The Puritan or nonconformist party had meanwhile gathered strength, and soon after the arrival of the new sovereign in London they presented to him a petition in favor of a further revision and purification of the liturgy. The result was the so-called Hampton Court conference, participated in by eminent clergy of the established church and of the nonconformist bodies, and which met on Jan. 14, 1604, in presence of the king and the privy council. The king considered the demands of the Puritans untenable, and broke up the conference on the third day; but under the clause of the act of uniformity by which Elizabeth had authorized a revision of the calendar, he directed a few changes to be made in the prayer book, of which the most important seem to have been the questions and answers concerning the sacraments subjoined to the catechism, and the restriction of the administration of baptism to regularly ordained ministers. With the triumph of parliament in the reign of Charles I. the opponents of the prayer book succeeded in 1645 in getting it entirely suppressed, and for fifteen years it passed almost out of sight. The restoration of the royal family brought it again into favor, and subsequent to July, 1660, as Evelyn records, it was publicly used in the churches. In March, 1661, Charles II. summoned a number of divines, representing equally the established church and the nonconformists, to meet in London and review the "liturgy of the church of England, contained in the Book of Common Prayer, and by law established." This assembly, called from its place of meeting the "Savoy conference," was the last official attempt to reconcile the differences of opinion between the advocates and the opponents of the prayer book. Its sessions extended from April 15 to July 24, 1661, and were barren of any practical result. A strong reaction had taken place in favor of the church party, and the nonconformists, though represented by such men as Baxter and Calamy, were not sufficiently united in their plan of opposition to accomplish their object. Baxter even drew up a substitute for the prayer book, which failed to meet the approval of his friends. The work of revision was then committed to the convocations of the provinces of Canterbury and York, by which a number of slight changes were made, which seem to have been in the opposite direction from that desired by the nonconformists. A service was also provided for the baptism of those of riper years, and a form of prayer to be used at sea. The prayer book thus revised, together with an act for uniformity of public worship, was approved by parliament in 1662, and went into immediate use.

A further attempt in the reign of William III. to revise it proved unsuccessful, and the prayer book of 1662 remained unaltered till 1872, when a new lectionary or course of lessons from the Scriptures was introduced, which is made optional till 1879. In the new lectionary many chapters from the Apocrypha are omitted. Previous to 1859 it was customary to include in modern editions of the Book of Common Prayer four services for special days of the year, known as "state services," which, however, properly formed no part of the book. Three of these services, being forms of prayer for the 5th of November, in commemoration of the discovery of the gunpowder plot of 1605; the 30th of January, the anniversary of the execution of Charles I.; and the 29th of May, the birthday of Charles II. and the anniversary of the restoration of the royal family, were in the year above mentioned abolished by act of parliament. The fourth, a form of prayer for the accession of the reigning sovereign, has been retained.—For many years after the reformation no attempt was made to introduce a uniform system of worship in Scotland, although Knox's "Book of Common Order" was very generally used. In deference to the wishes of James I. the general assembly in 1616 decided in favor of a uniform order of liturgy; but nothing was done in the matter till after the accession of Charles I., who was very desirous of having the English prayer book adopted by the church of Scotland. The Scottish bishops, however, preferred to frame a liturgy of their own, and eventually an episcopal committee was appointed to carry this design into execution. The committee after several years' labor, in which they were aided by suggestions from Archbishop Laud, completed their prayer book in 1636, and in 1637 it was imposed upon the church of Scotland by letters patent and the authority of the bishops, without having been submitted to the general assembly. It was modelled after the English prayer book of the time, with a number of slight variations; but the communion office rather followed the form in the first book of Edward VI. The book encountered vehement opposition, and was almost immediately suppressed. From that time until the close of the 18th century the Scottish Episcopal church and its liturgy remained in comparative obscurity, being for many years under the operation of penal laws. The prayer book was several times revised, notably in 1765, and is now in most respects identical with that of the church of England. The communion office, however, retains many features peculiar to the first book of Edward VI.; and certain ancient usages, such as the sign of the cross at confirmation. the mixture of water with wine at the eucharist, and the dismissal previous to the consecration of the elements of those not intending to communicate, are still enjoined by rubric.—Until the disestablishment of the Irish Episcopal church on Jan. 1, 1871, its prayer book was identical with that of the church of England, except that it contained a few additional services, such as a form for the visitation of prisoners, a form of consecration or dedication of churches and chapels, and a prayer for the lord lieutenant. One of the declarations prefixed to the constitution of the disestablished church enjoins the use of the Book of Common Prayer, "subject to such alterations only as may be made therein from time to time by the lawful authority of the church." In the first synod, which met in April, 1871, a number of attempts to alter the liturgy and formularies failed of success, and the subject of revision was referred to the bishops and to a mixed committee of clergy and laymen, who were directed to report in the succeeding year. The synod of 1872 declared the word priest to be synonymous with presbyter, and authorized the shortening of the services on week days and the dividing of them. It also approved of a recommendation for the omission of the rubric on ornaments. Propositions to remove the damnatory clauses from the Athanasian creed, and to allow deacons to pronounce absolution, were defeated, which was declared to be equivalent to a withdrawal of those subjects from further consideration by the synod. The committee was then reappointed and directed to report in 1873.—Previous to the American war of independence members of the church of England in the British North American colonies were under the episcopal supervision of the bishop of London, and used the English Book of Common Prayer. Immediately upon the acknowledgment by Great Britain of the political independence of the United States, measures were taken to establish an American Episcopal church, and to compile a service book for its use. The initiatory step was taken by Connecticut, where in March, 1783, a convention of Episcopal clergy recommended Dr. Samuel Seabury to the English bishops for consecration to the episcopate. Owing to certain technical legal difficulties, this could not at once be effected, and Dr. Seabury went by advice to Scotland, where on Nov. 14, 1784, he was consecrated at Aberdeen by the bishops of the Scottish Episcopal church. Meanwhile a convention, participated in by Episcopalians from various states, had met in New York in October, 1784, and adopted a series of articles, one of which provided "That the said (American) church shall maintain the doctrines of the gospel as now held by the church of England; and shall adhere to the liturgy of the said church, as far as shall be consistent with the American revolution, and the constitutions of the respective states." Pursuant to the recommendations of this body, another convention assembled in Philadelphia in September, 1785, which put forth a volume known as "the proposed book," embodying many important variations from the English Book of Common Prayer. These were of two kinds, political and doctrinal. Under the former head all passages referring to the royal fam-

ily and government of Great Britain were either entirely omitted or adapted to the new political relations of the country, and the so-called "state services" of the English prayer book were stricken out. The chief changes under the second head were the rejection of the Nicene and Athanasian creeds, and the omission of the words "He descended into Hell" from the apostles' creed. The convention of 1785 also recommended to the English church for consecration as bishops Dr. William White of Philadelphia and Dr. Samuel Provoost of New York. But before this act was consummated a copy of the "proposed book" reached England, and elicited from the archbishops of Canterbury and York an expression of disapprobation, not only at various verbal alterations that seemed uncalled for, but at the radical changes made in the three ancient confessions of faith which had always been accepted by the church of England. Whether or not in consequence of this remonstrance, the American Episcopal convention which met at Wilmington, Del., in October, 1786, restored to the prayer book the Nicene creed, allowing it to be used as an alternative instead of the apostles' creed both in the communion and daily offices. The clause "He descended into Hell" was also restored to the apostles' creed, with the rubrical provision that "any churches may omit the words, 'He descended into Hell,' or may instead of them use the words, 'He went into the place of departed spirits,' which are considered as words of the same meaning in the creed." No change, however, was made in the resolution of the convention to discontinue the use of the Athanasian creed in divine service. These concessions having removed the scruples of the English prelates, Drs. White and Provoost were consecrated bishops of Pennsylvania and New York in February, 1787. The general convention which met at Philadelphia in September, 1789, undertook the final revision of the liturgy. A house of bishops was now for the first time organized as a distinct branch of the convention; and although but two of the three members composing it, Bishops Seabury and White, were present, the influence which they exerted prevented any such radical alteration of the prayer book as was desired by a strong party in the house of clerical and lay deputies. The bishops were determined to hold the English prayer book as the basis of their work, and to avoid as far as they could all unnecessary changes; and to their tenacity of purpose and ready coöperation is due the fact that in all their main features the liturgies of the Anglican church in the United States and the mother country are identical. Apart from the changes above noticed, the chief differences between the English and the American Book of Common Prayer, as the latter was settled by this and subsequent conventions, are the following: Many changes of words and phrases have been made with a view to the removal of what was obsolete, or in order to attain greater correctness of expression. In morning prayer and evening prayer the Lord's prayer is directed to be said but once; in both offices the versicles and responses have been abridged; and from evening prayer the *Magnificat* or song of the Virgin and the *Nunc dimittis* have been excluded. The lectionary, or lessons from the Bible, has been in part remodelled, the portions from the Apocrypha being omitted. A "Selection from the Psalms," instead of the portion of the Psalms appointed for the day, is allowed to be used at the discretion of the minister. The *Gloria in excelsis*, found only in the communion service in the English book, is allowed in morning and evening prayer as an alternative with the *Gloria Patri;* and the form of absolution peculiar to the communion service is similarly introduced into morning and evening prayer. The communion service, owing to the influence of Bishop Seabury, was borrowed from the Scottish office, although the order of the English office is generally retained; the distinguishing feature consisting in the incorporation into the prayer of consecration in the American book of the oblation and invocation according to the new Scottish office as revised in 1765. In the baptismal office the minister is permitted to dispense with the sign of the cross after sprinkling the candidate. In the office for the visitation of the sick the rubric directing the minister to advise sick persons to confess their sins, and also the form of absolution, are stricken out. The marriage service is considerably abridged, and the commination service for Ash Wednesday is omitted. From the calendar all names of saints not commemorative of persons and facts of Scripture history have been excluded; and services for the visitation of prisoners, for the consecration of a church or chapel, and for the institution of ministers have been added. Finally, to show their desire to adhere substantially to the English liturgy, the American revisers state in the preface to their Book of Common Prayer that "this (American) church is far from intending to depart from the church of England in any essential point of doctrine, discipline, or worship; or further than local circumstances require." It is customary to include in the English and the American Book of Common Prayer the "Articles of Religion" adopted by the churches of the Anglican communion; also metrical versions of the Psalms and a collection of hymns to be used in divine service. These, however, are not properly a portion of the book, the standard edition of which ends with "The Psalter or Psalms of David." The American prayer book came into general use on Oct. 1, 1790, and in its essential features has remained unchanged to the present day.

COMMON SCHOOLS. Under the general head of Education will be found a condensed history of instruction, public and private, so far as there are data for such a history. Under

the present title will be given only an outline of the development of the great principle of the free elementary education of every child in the community. It would naturally be supposed that in every well regulated state the advantage of the universal education of the community would be so obvious that measures would be taken to effect it almost from the origin of the state. This, however, has been only partially the case. In Sparta under the system of Lycurgus the state undertook the education of the children, but the instruction imparted was mainly physical, and did not reach the peasant classes. In Attica there were public schools for all classes, and this had its influence in making Athens the university city of the ancient world. The education of the children was a religious duty among the Jews, and after the captivity they developed an excellent system of parochial schools in connection with the synagogues. In Rome, while private schools were numerous, their advantages only accrued to the patricians and such plebeians as possessed property; yet after the conquest of Gaul important schools were established in the imperial cities. After the introduction of Christianity and its accession to power, the duty of the authorities to educate the young was speedily recognized by the bishops and clergy. The object of this education was of course their training in the doctrines of Christianity, but it was the recognition of the duty of giving instruction to the masses. In 800 a synod at Mentz ordered that the parochial priests should have schools in the towns and villages, that "the little children of all the faithful should learn letters from them. Let them receive and teach these with the utmost charity, that they themselves may shine as the stars for ever. Let them receive no remuneration from their scholars, unless what the parents through charity may voluntarily offer." A council at Rome in 836 ordained that there should be three kinds of schools throughout Christendom: episcopal, parochial in towns and villages, and others wherever there could be found place and opportunity. The third Lateran council in 1179 ordained the establishment of a grammar school in every cathedral for the gratuitous instruction of the poor. The ordinance was enlarged and enforced by the council of Lyons in 1245. This idea of popular education has been carried out by the zealous efforts of the Jesuits and other religious orders. While in the large towns and cities considerable numbers of the poor thus received the rudiments of knowledge, in the more scattered population of the rural districts very few could read or write. At the era of the reformation the cause of popular schools received a further impulse. In 1524 Luther wrote an "address to the common councils of all the cities of Germany, in behalf of Christian schools;" and in 1526 he wrote to the elector of Saxony strongly urging the application of the monastic funds to the support of schools for the poor. In 1528, with the aid of Melanchthon, he drew up the Saxon school system, as it was called, and through life the education of the young of all classes in free schools was one of the objects nearest his heart. The labors of Luther in this field were continued by his followers, and the Germans seemed destined to become the best educated people in Europe; but the breaking out of the thirty years' war in 1618 arrested the progress of all educational improvements. About the middle of the 17th century several of the German states passed laws making it compulsory on parents to send their children to school during a certain age. In the latter part of that century two men appeared whose labors introduced a new era into the history of education in Germany. They were Philip Spener and August Francke. The latter gave an impulse to the cause of popular education which, through the influence of his disciples and followers, such as Zinzendorf, Steinmetz, Hecker, Basedow, Campe, Salzmann, and Pestalozzi, has been continued to our own times. In Prussia the movement in behalf of a thoroughly popular system of education, though more fully sustained than in any other country on the continent, did not commence till the early part of the present century. Enactments rendering the attendance of the children at the schools compulsory had been upon the statute book since 1717, but it was not till 1809 that the habits and good will of the people were enlisted on the side of education. The Prussian schools are by law as accessible to the poorest as to the richest, and every provision is made for adapting them fully to the wants of the people and the government. Scotland is the only other country of Europe which had at an early period a system of common or popular schools. These, like those of the early church on the continent, originated with the clergy. In 1560 John Knox urged the necessity of schools for the children of the poor, to be sustained at the charge of the kirk. The act of 1696 established common schools in every parish, to be supported in part by the parish, and in part by rate bills. These schools, which have diffused a more general elementary education among the people of Scotland than exists in any other nation in Europe except perhaps Prussia, have always been under the charge of the kirk; and since the secession of the Free church in 1843, schools have been organized in connection with each of its congregations.—The fullest and most complete development of the common school system, however, has taken place in America. The Puritan settlers of New England were fully convinced of the necessity of universal education; and as soon as they had provided temporary shelter for themselves, they reared the church and the school house. But the first schools established in the country were not common or public schools. Free grammar schools, as

they were called (that is, schools in which Latin was taught, and which were supported in part by the proceeds of land, houses, or money granted either by the town or by individuals, and in part by tuition money, and which were free only to the donors, and to them only in part), were established in Charles City, Va., in 1621, in Boston in 1636, in New Haven in 1638, in Salem in 1641, in Roxbury prior to 1645, and in most of the towns of New England within four or five years after their settlement; but these, though comprising at first perhaps the major part of the children of the settlement, were not common schools in the present sense of that term. The free public school (the common school of our time) was of New England origin, but whether it was first established in Massachusetts or Connecticut is a mooted point. Acts in regard to popular education were passed by the general court of Massachusetts in 1642 and 1643. The law of the latter year provided as follows: "It is therefore ordered that every township in this jurisdiction, after the Lord hath increased them to the number of 50 householders, shall then forthwith appoint one within the towne to teach all such children as shall resort to him to write and reade, whose wages shall be paid either by the parents or masters of such children, or by the inhabitants in generall by way of supply, as the maior part of those that order the prudentials of the towne shall appoint, provided those that send their children be not oppressed by paying much more than they can have them taught for in other townes." But if the general assembly of Massachusetts were foremost in legislative action for popular education, the town authorities of Hartford, although a younger colony, had at an earlier date taken broader and more liberal ground for the education of all classes; and as Hartford was the central and controlling settlement of the Connecticut colony, its action was but the precursor of the legislative action which followed a very few years later. A town school was established prior to 1642, and the funds for its support were voted from the town treasury; and in 1643 a vote was passed, which in its spirit still governs the educational system of the state, "that the town shall pay for the schooling of the poor, and for all deficiencies." The colonies of New Hampshire and Vermont followed the example of Massachusetts and Connecticut, and established schools in every hamlet where the number of inhabitants and of children was sufficient to furnish employment and support to a teacher. The records of the general courts and of the towns show that the prosperity of these "fountains of intelligence," as they appropriately called the common schools, was an object of common solicitude; and though very heavily taxed for other objects, they never forgot to support and sustain the common school. We have seen that in Germany the thirty years' war broke up the system of public schools which Luther and his successors had reared with so much care; but in New England, amid almost incessant conflicts with the Indians and French, when the male population was greatly reduced in the successive campaigns, the abandonment of the schools was not even thought of. In 1670 the commissioners of foreign plantations addressed to the governors of the colonies several questions relative to their condition. To one respecting the means of education, the governor of Connecticut replied: "One fourth of the annual revenue of the colony is laid out in maintaining free (common) schools for the education of our children." To the same question Gov. Berkeley of Virginia replied: "I thank God there are no free schools nor printing, and I hope we shall not have these hundred years." Soon after the close of the revolutionary war, the lands in Ohio known as the Western Reserve, belonging to Connecticut, came into market. The proceeds of that vast tract, amounting at the time of sale in 1795 to $1,200,000, were consecrated to the support of the common schools of the state. To the same cause Massachusetts set apart a portion of her wild lands in the then province of Maine. The New England school system at the commencement of the present century was based upon the following ideas: 1, the instruction of all the children of the state in the rudiments of an English education, viz., reading, writing, elementary arithmetic, elementary geography, and grammar—this to be accomplished by schools in every precinct or district containing 50 householders, or even a smaller number; 2, each district to be independent of every other in its financial matters, hiring of a teacher, &c.; 3, a superintendent or board of visitors in each town or school society, generally consisting of professional men, and almost invariably including the clergy, to examine the teachers, inspect the schools, prescribe text books, &c.; 4, the support of these schools by taxation and rate bills, the poor being exempted from the latter; 5, power of compelling attendance on the part of the town authorities. Under this system, which was extended to New York, Ohio, Pennsylvania, and the other northern and northwestern states, a moderate amount of education was diffused through the entire community. In time, as the result of a routine system, it became apparent that the standard of education had been lowered rather than raised. The attention of philanthropic men in all parts of the country was directed to the subject, and in 1817 and the following years commenced a revival of education, the influence of which is still felt. The movement resulted in the establishment of the public school society in New York, and of improved school organizations in many other cities; the revision of the school systems of most of the New England and of several of the middle and southern states between 1821 and 1828; the efforts of Thomas H. Gallaudet, James G. Carter, and Walter R.

Johnson, through the press, to elevate the standard of instruction and to create institutions for the professional training of teachers; the establishment of the "American Journal of Education" in January, 1826, afterward called the "American Annals of Education;" the improvement of text books; conventions, town, county, and state, held throughout New England from 1826 to 1830 in behalf of common schools; the subsequent organization of teachers' institutes and associations; the founding of normal schools; the zealous and unwearied efforts of Horace Mann, Henry Barnard, and others; the plan of lecturing in every precinct in the states on the subject of education; and the establishment of local school periodicals, as well as of those of a more general character. In the United States the organization and control of the common schools are left to the respective states; hence there is no uniform common school system, but a wide diversity of plans is presented. The variances, however, relate chiefly to details, while the following leading features may be regarded as common: 1. A system of graded schools for each town, embracing (*a*) primary schools for the younger pupils; (*b*) grammar schools for the older, in which are taught, in addition to the ordinary branches, natural philosophy, chemistry, history, and frequently drawing, vocal music, algebra, geometry, French, and German; (*c*) high schools for the more advanced, in which are taught the studies necessary for a business education, and in most cases the languages and higher mathematics. 2. The placing these under the constant supervision of one or more efficient visitors, who ascertain by thorough examination the qualifications of the teachers. 3. The enforcement of uniformity of text books, and regularity and punctuality of attendance. 4. Regular and frequent public examinations. 5. The establishment of school libraries in connection with all the schools. 6. The introduction of blackboards, globes, orreries, maps, charts, outline maps, and other apparatus for instruction. 7. The proper construction of school houses, for ventilation, warming, convenience of instruction, and promotion of order. 8. The establishment of normal schools for the instruction of teachers, and the holding of teachers' institutes for exercise and drill of those already engaged in instruction. 9. The organization of state teachers' associations for comparison of methods of teaching, and the establishment of state periodicals devoted to schools. 10. The extension of the privileges of these schools to all the children of school age in each state, either by supporting the schools entirely by taxation and the income of funds where they exist, or by taxation and small rate bills, which are abated where there is inability to pay, and the furnishing the necessary text books to the children of the poor. The study of drawing, music, and German as regular branches in the common school has recently been widely extended. The introduction of evening schools into the common school system is of recent origin; but there has been a marked development in this department of public instruction. These schools are intended for those whose employment prevents them from attending the day schools, and are found chiefly in cities and the larger manufacturing towns. Some of the states have the advantage of considerable funds to aid in the support of their schools. The western states generally will be largely endowed, as the 16th section of every township is granted for school purposes by the national government, and other lands also are granted by the states. The land granted by the United States for school purposes amounts to about 68,000,000 acres, which has been estimated to be worth more than $60,000,000. In most of the states the schools are under the supervision of a board of education or a state superintendent, generally elected by the people, but in a few instances receiving their appointments from the governor or legislature. In some of the states the system also comprises county superintendents. In several of the states laws have been passed making attendance at public or private schools compulsory for a specified period, varying from 16 months between the ages of 5 and 18 years, to 4 months each year; while in other states those districts in which schools are not open for a specified period are not entitled to any portion of the school fund. Provision for compulsory attendance at school has been made in the constitutions of Arkansas, Missouri, North Carolina, South Carolina, Texas, and Virginia, and in other states laws are in force compelling parents to send their children to school. In Kansas, Nevada, Arkansas, Nebraska, Ohio, and South Carolina sectarian instruction and control are forbidden by the constitution. Prior to the civil war the southern states had no well organized school system; but in the adoption of new state constitutions after the war provision was generally made for the establishment of free common schools. Much progress has been made toward carrying into effect these provisions and perfecting the free school system. The common school funds in the various states generally consist of such grants of land as have been made by the general government for school purposes, and the investment of funds arising from sales of the same, together with those accruing from state and individual endowments, and the proceeds from taxation, including poll and property taxes. In 1867 a law was passed by congress establishing a bureau of education for the purpose of collecting such statistics and facts as shall show the condition and progress of education in the several states and territories, and of diffusing such information respecting the organization and management of school systems and methods of teaching as shall aid the people of the United States in the establishment and maintenance of efficient school systems, and otherwise promote the cause of education through-

out the country. This bureau is in successful operation, and publishes annually a report showing the condition of the common schools and other educational institutions in each state.—According to the census of 1870, the number of public schools in the United States was 125,059, employing 183,198 teachers, of whom 74,174 were male and 109,024 female. The number of pupils in attendance was 6,228,060, including 3,120,052 males and 3,108,008 females. The total income during the year ending June 1, 1870, was $64,030,673, including $144,533 from endowments, $58,855,507 from taxation and public funds, and $5,030,633 from other sources, including tuition. These statistics do not include private schools, or classical, professional, and technical institutions. The following statistics of common schools in the United States are from the report of the bureau of education for 1872:

STATES, AND TERRITORIES.	Between the ages of—	Number enrolled.	Average attendance.	No. of schools or school districts.	Average duration of school in months and days.	No. of teachers.			Average salary of teachers per month.		Income.	Expenditures.	Amount of permanent school fund.

COMMONS, House of. See PARLIAMENT.

COMMUNE DE PARIS. **I.** The name of a revolutionary committee which played a most important part in France from July 14, 1789, to July 27, 1794. On the first insurrection the Parisian electors convened, and under the above name appointed a standing committee, which, on the eve of the taking of the Bastile (July 13, 1789), established the Parisian militia or national guard. A decree of the constituent assembly, May 21, 1791, divided the commonalty of Paris into 48 sections, electing a mayor and 16 administrators, to which a municipal council of 32 members and another board of 96 notables were added. On Nov. 10, 1791, Pétion was elected mayor; Robespierre, Billaud-Varennes, and Tallien entered the general council, while Manuel held the office of attorney, and had Danton as his first assistant. Henceforth the commune acted in concert with the Jacobins, and on the night of Aug. 10, 1792, established themselves as the insurrectionary commune, declared all other authorities suspended, and soon became the ruling power, and spread terror among the royalists by the slaughters of September. Next they joined the Montagnards, and organized the insurrectionary movements which resulted in the fall of the Girondists, May 31 and June 2, 1793. During the reign of terror they remained faithful adherents of Robespierre until his overthrow. Their very name was suppressed by the constitution of the year III., under which the city of Paris was divided into 12 distinct municipalities, and the commune entirely lost its political importance. **II.** A revolutionary attempt to establish absolute municipal self-government in Paris in 1871. First openly begun by the resistance of the national guard to the regular forces on March 18, in some degree organized by the municipal elections of the 26th, and assuming definite shape through the

formal proclamation of the commune on the 29th, it was finally suppressed by the troops of the national government two months later, after having in the interval become complicated with attempts to carry out various notions of socialism, and with other schemes of revolution apparently not comprehended in the original design, and certainly not stated as a part of it. The red republicans and the more violent reformers of Paris had, since the dethronement of Napoleon III. and the proclamation of the republic in September, 1870, never ceased to attack what they considered the conservative character of the government of national defence then established, and to demand more radical measures, especially such as should tend toward decentralization, municipal independence, and the introduction of something approaching a federative system made up of self-governing communes. Diligently and sincerely advocated by many of the leading radical politicians, and industriously propagated for their own purposes by political agitators, revolutionists, and adventurers in the city, these opinions gained ground very rapidly among the people. They already formed one of the many articles in the political programme of the working men's societies, especially in that of the widespread *internationale*. By many they were undoubtedly accepted understandingly and with due knowledge of the end to be gained; but they were largely used as a political device by demagogues and the lowest order of revolutionary popular leaders, who represented to the laboring classes the establishment of municipal self-government as the beginning and the means of various more or less vaguely stated reforms in their condition. Thus the cry of "*Vive la commune!*" used intelligently by the few, became besides, like so many similar cries before it, the expression of the discontent and the somewhat aimless though violent agitation of the revolutionary proletarians. This agitation, though its expressions were generally confined to the radical clubs—like that of the Salle Favié at Belleville, that of the Alcazar, and many others—had already broken out several times during the German siege of Paris in riotous demonstrations originating in one of the suburbs Montmartre, Belleville, or La Villette, and having for their object the possession of the hôtel de ville. The most important of these was that of the 31st of October, 1870, when the mob, infuriated by the news of the surrender of Metz and the defeat at Bourget, fairly gained possession of the place, and even of the members of the government in session there at the time, but were compelled to withdraw by the national guard, though only on condition that a vote determining the confidence or want of confidence of the people of Paris in the government of national defence should immediately be taken. This vote was ordered for Nov. 3, when the government was sustained by overwhelming majorities; but the radical leaders had shown their growing power, and this riot was the most unmistakable herald of the coming insurrection. Finally, when the long series of French defeats and unsuccessful sorties terminated in the surrender of the capital to the Germans, and the idea, "The government has betrayed us," gradually gained ground among the people, the national guard began to waver, then to join openly in the clamor, until finally, by making the first really formidable insurrectionary movement, they themselves became as it were the leaders in the revolutionary attempt from which they had before comparatively stood aloof. On the triumphal entry of the German army into Paris, March 1, 1871, detachments of the nationals, who had by express stipulation been suffered to remain under arms "for the preservation of order," made hostile demonstrations in violation of the agreement of the government, erecting barricades in several portions of the city, and remaining in an attitude of resistance; and they placed themselves in still more decided opposition to the authorities by their refusal, in spite of the formal order of Gen. Aurelle de Paladines, the commandant, to give up the artillery which had been removed on Feb. 26 from the parc Wagram and other places, ostensibly to preserve it from falling into the hands of the Germans. Thus taken into their possession under cover of a purpose which, though in direct violation of the armistice agreement, passed for a patriotic one, this artillery proved one of the chief sources of their strength in the beginning of the insurrection. The government did not at first attribute to this direct resistance to its authority the importance which it possessed; and in the interval of temporizing policy which followed, the insurrection grew stronger with great rapidity. The first step taken, the commune leaders won adherents by thousands. The negotiations of the authorities with the Germans aided them; for not only was there a great number of the people to whom the thought of peace on the apparently inevitable terms was, from purely national pride and patriotic feeling, almost unbearable, but there was also a perhaps still larger class, composing the worse portion of the national guard especially, which saw in the end of the war the end also of their living at government expense, and looked forward to the return of hard labor, the enforcement of creditors' claims, the collection of rents, and a thousand evils they had evaded during the war. Both these classes, and many more, flocked eagerly to the standard of the commune, whose leaders raised the cry, "The republic is in danger!" and in a few days the insurrection became too formidable to be checked. An organized body now appeared as its head. This was the central committee of the national guard, a council of leading insurgents, at first under the controlling influence of Blanqui, which had long acted as a half-concealed conspiracy, but now came forward openly. Its power was for a time threat-

ened by another committee claiming to be the regularly elected representatives of a federation of battalions; but a fusion was effected between the two, and the central committee, thus reconstructed, found itself with even greater influence than before. Acting under its orders, the insurgents had taken the cannon on Feb. 26; directed by it, they now possessed themselves of great quantities of arms and ammunition from the fortifications, and took up their principal position in an intrenched camp on Montmartre. They took magazines, compelled the release of public prisoners, and even came into open conflict with small bodies of regular troops, some of whom were induced to join them. They began to call themselves the "federated guards," in distinction from those nationals who had remained loyal. From its stronghold at Montmartre the central committee issued inflammatory proclamations, demanding that the national guard should have the right to elect all its own officers; that the daily pay (war standard) of one franc and a half should be secured to each of its members until he could obtain work, or the government could obtain it for him; that Gen. Aurelle de Paladines should be displaced to make room for a commandant of their own choosing. In what concerned general politics they demanded universal suffrage, and the formal subjection of all military power to the civil authority of the Paris municipality. The greater part of these demands were sent to the minister of the interior, with much of the formality attending the presentation of an ultimatum from a hostile power. —Such was the position of affairs when the new national government, headed by M. Thiers, at last perceiving with what they had to deal, determined upon the employment of force. They rapidly collected the troops that could be spared from other employment, and brought the detachments stationed in Paris up to the strength of 30,000 men, including that minority of the national guard that remained loyal. On March 11 Gen. Vinoy, to whom the task of dealing with the matter was largely intrusted, had, just after the receipt of the demands of the reds, suppressed six of the most violent radical journals, *Le Vengeur* (the organ of Félix Pyat), *Père Duchêne*, *Le Cri du Peuple*, *La Bouche de Fer* (the organ of Paschal Grousset), *La Caricature*, and Rochefort's paper, *Le Mot d'Ordre*. With the exception of this, however, no decisive act had revealed the intentions of the government; the quieter classes of Parisians, with singular blindness, seemed to have no idea of an approaching conflict; the difficulty, if referred to at all, was spoken of lightly as "the cannon question;" the insurgents on Montmartre remained quiet for several days; and a lull preceded the final crisis which promoted a general sense of security, and gave the outbreak when it came additional violence. On the night of March 17–18, 10,000 of the government troops finally took up positions of attack about the base of Montmartre. These occupied, they pressed on to the summit of the hill, easily overcame the few guards stationed about the camp of the insurgents, took 400 prisoners and several cannon, and before daylight made themselves masters of the place without encountering formidable resistance. So quietly was this done, that no general knowledge of the movement spread through the other quarters of Paris at the time; the morning papers appeared without mentioning the events of the night, and the victors flattered themselves that the whole trouble was at an end. But some apparently trifling errors in their plan caused them to be very quickly undeceived. Nothing now remained to complete the success but the removal of the cannon; but the arrangements for carrying them away having been incompletely made, a long delay ensued, and meanwhile the news of the affair spread rapidly through the insurgent districts near at hand, and among the federated guards, the fellows of those who had been captured. The general alarm was beaten in the quarters of Belleville and Montmartre; the populace poured into the streets; and about 7 o'clock several battalions of federates, hastily mustered, attacked the government troops, with whom a violent and irregular conflict followed. Suddenly the 88th regiment of the line, among those engaged, threw up the butts of their muskets and went over to the federate side, and their example was followed later by other regular soldiers, while new reënforcements from the hostile quarters reached the insurgents constantly. Gen. Vinoy had drawn a cordon of troops around the hill, ordering them to permit no one to pass, and planting mitrailleuses covering the various roads of ascent. But these precautions were rendered useless by the fraternization of the soldiers with the people; the insurgents carried off the mitrailleuses, and the few troops remaining loyal saw themselves compelled to withdraw. In the place Pigalle a small body of such troops (200 to 300 men), commanded by Gen. Faron, was cut off from the rest in their retreat, and only succeeded late in the day in cutting a way out after a fierce conflict. Gen. Lecomte and the former commander of the national guards of Paris, Gen. Clément Thomas, deserted by their soldiers, were taken prisoners by the federates and the people, and after being insulted and maltreated by the mob they were led before the central committee, which commanded that they be held as prisoners of war. In spite of this decree, they were taken later in the day by a few federate guards into a little garden near by, and shot, Gen. Thomas, it was said, falling at the fifteenth discharge. By noon of the 18th the insurgents were once more in full possession of Montmartre and its surroundings, where they set about erecting street barricades and other defences; and toward evening, the government troops having been driven from the field, they penetrated into other quarters of the city, and first

took possession of the place Vendôme and the army headquarters there. Soon after dark they occupied the hôtel de ville without meeting any resistance; by midnight they were fairly established in it, and the national troops had been withdrawn to Versailles. The morning of the 19th found every attempt at control on the part of the government abandoned, every point in the power of the federate guards, and the central committee the rulers of Paris. Making their headquarters at the hôtel de ville, they immediately issued three proclamations, which appeared early in the day; and so short had been the conflict for the possession of the city, that a great part of the people in the distant quarters learned for the first time through the placarding of these manifestoes that a revolution had been effected, and that a new power was fairly established over them. The first proclamation announced the "triumph of the people" over those who had wished to destroy the republic, and exhorted the people of Paris to assemble for communal elections; the second addressed the national guard, and declared that the central committee, having "fulfilled the mission" intrusted to them by their fellows of defending "Paris and their rights," were now ready to surrender their trust to those whom the people should elect in their communal districts; and the third finally fixed the communal elections for the 22d, owing to the urgent necessity for a communal administration. The red flag was hoisted on the hôtel de ville, the prefecture of police and the department of finance were taken possession of by prominent insurgents, and the earlier half of the day was spent by the committee in deliberation as to their next action. Strange to say, the general population of the city remained indifferent and passive, though a number of citizens, who recognized Vice Admiral Saisset on the boulevard, begged him to organize some resistance to the reds; he declared, however, that he would not act without orders from Versailles. But a few representatives of the national authority still remained in the city, in the persons of the *maires* of the various arrondissements. These met at 3 o'clock at one of the *mairies*, and, consulting with delegates from the committee, agreed during the evening upon a compromise by which the matter was to be submitted to the national assembly, and the hôtel de ville was to be given up to the maires. A peaceful solution of the whole conflict seemed for a moment possible; but when on the morning of the 20th the proper authorities went to take possession of the hôtel, they were told that the committee had retracted its decision, and affairs resumed their old aspect. On that day another proclamation was issued, again stating the rights claimed by the national guard, declaring that the committee would faithfully carry out the preliminary agreements made with the Germans, as the revolution was not concerned with any but home politics, and appealing to the provinces to join in the movement for self-governing communes. This appeal was almost entirely without effect, although Blanqui had already left Paris, undoubtedly with the purpose of securing aid from the rest of France. Attempts at insurrection were indeed made in Marseilles, Lyons, Rouen, Toulouse, and one or two other cities, but all were soon suppressed. Blanqui, so long the head and front of the uprising, was arrested in southern France, and immediately imprisoned. The communal elections were postponed to the 26th. Vice Admiral Saisset, now acting under official appointment from Versailles, made one more attempt at negotiation by the issue of a proclamation in which the greatest possible concessions were promised; but the time had passed, and, beyond conveying the impression that the government was frightened, the offer produced no effect. Yet, still deceived by the hope of peace, Saisset on the 25th disbanded the defenders of the national government who had organized and rallied around him, and by this step destroyed the last hope of resistance; the only other attempt to excite it having been made by a few citizens who were cut to pieces in the rue de la Paix, March 22. From the 25th no further opposition occurred within the city walls, and Paris was given over to the new régime. In the mean time the committee had taken the most energetic military measures for sustaining their power. The federate guards raised complete lines of barricades connecting all the important strategic points of the city; a strict organization was introduced among the 250 battalions that now formed the committee's army; the great stores of ammunition accumulated in Paris during the siege were seized; the number of cannon in the possession of the insurgents was increased by further seizures to 2,000; the defences of the walls were diligently strengthened; the forts, with the very important exception of Mont Valérien, which was in the government's hands, and such of the eastern and northeastern fortresses as the Germans still held, were taken and occupied by the federate troops; and complete preparations were made for the defence of the city against a siege.—On March 26 the elections for 94 members of a communal government occurred in Paris; only 85 were actually chosen, however, owing to the fact that in some cases two sections united upon the same candidate. It was afterward proved that fewer than 200,000 of the people had voted, and thus that the government party would probably have been in the majority if it had been organized and had dared to cast its ballots; but however this may be, the elections were of course overwhelmingly in favor of the leading candidates of the insurgents. Of these, 13 were members of the central committee, 17 were members of the internationale, and 20 belonged to what was distinctively known as the Blanqui party. There were also 17 mode-

rate and conservative politicians elected from the wealthier districts of Paris, but they almost immediately resigned. Among all the delegates there were comparatively few whose names were well known. Assi, Varlin, and Duval, prominent members of the internationale; Félix Pyat, the journalist and *littérateur*, author of the *Chiffonnier de Paris;* Raoul Rigault, a cynical and bitter revolutionist, recalling the men of terror of nearly a century before; Paschal Grousset, a journalist admired less for his revolutionary qualities than for elegance and polish of manner; Gustave Flourens, the son of the great physiologist, and himself a man of much scientific and literary cultivation; Vermorel, a journalist of the quartier Latin; Vesinier, the former secretary of Eugène Sue, and himself the author of a few novels; Gambon, a hero of the insurrection at Bordeaux; Tridon, a revolutionist of Rigault's school: these were among those elected to the new governing body. There was also the stern old republican and Jacobin Delescluze, and M. Bislay, an uncompromising republican, to whom the excesses of the commune were entirely foreign. Victor Hugo and Rochefort were also elected, but withdrew without having taken any part in the principal events. Blanqui's name, in spite of his absence, appeared on the lists; he was elected, and a substitute appointed to represent him. Gustave Paul Cluseret, who had already taken part in many insurrections, and was one of the few whose practical knowledge of military affairs could be of advantage to the insurgents, was a candidate, but was not returned until a second election held April 16 to fill vacancies. He may almost be considered a member from the beginning, however, as he held office under the commune from April 3, as will presently be shown. On the 29th the first regular sitting of the newly chosen delegates was held at the hôtel de ville. The commune (by which name the new assembly now first officially styled itself) was declared to be the only true and legitimate government of the city; and a *Journal officiel de la Commune de Paris* was founded, in which a series of decrees was immediately published. The old revolutionary calendar was restored, March 29 being announced as the 8th Germinal, year 79; laws were issued requiring every healthy citizen from 19 to 40 to serve in the national guard; a provision granting partial remission of rents due since Oct. 1, 1870, was to go into force immediately, and no one could be arrested for the non-payment of such rents; the payment of all due bonds and notes might be postponed for three years from July 1, 1871, quarterly payments being made meanwhile; the daily pay of the national guards was raised to 2½ francs; all articles that had been pawned for a sum not exceeding 20 francs were to be returned to their owners; pensions were to be paid to the widows and orphans of those falling in the insurrection; all factories the possessors of which had left Paris were to become the property of the workmen employed in them; and a variety of minor provisions were to go into effect for similar purposes of relieving and satisfying the adherents to the new power. The commune now proceeded to organization; and the newly elected body found its early sittings the scenes of numberless quarrels. The military class of delegates had nothing in common either in aim or method with the working men; the journalists and politicians had a thousand theories and creeds; the men whose devotion to the cause was so strong and unselfish as to lift them above personal motives were in the minority; and among the others personal jealousies were constantly displayed. Many members began to neglect attendance on the meetings, and confusion reigned during the sittings at the hôtel de ville. After much discussion, however, an executive committee was formed, consisting of Bergeret, Duval, Eudes, Lefrançais, Pyat, Tridon, and Vaillant; commissions were formed for the administration of justice, the finances, military affairs, labor, public works, foreign affairs, and instruction, with committees on public safety, on subsistence, &c.; and the conduct of the commune's government assumed some definite shape. All this time the central committee of the federates, which had announced itself as so eager to give up its power into the hands of the commune, and had even proclaimed its resignation, continued sitting, refusing to keep its word, and insisting upon ratifying every measure of the commune before it took effect.—Both the delegates and their adherents were impatient to move upon Versailles, to gain possession of the national government there, to overpower the officials—"*écraser l'assemblée*," as the *Père Duchêne* expressed it. The attempt was fixed for April 2. In the forenoon of that day (Sunday) the troops of the commune, to the number of 5,000 to 6,000, were pushed forward in the direction of Mont Valérien. The national government, perhaps in the hope of still bringing about a settlement of the difficulty, but more probably following the characteristically cautious advice of M. Thiers, to render it manifest that the first direct hostilities came from the other side, sent a flag of truce to meet them. Its bearer was seized and shot, through whose fault does not clearly appear. A battle, or rather a skirmish, ensued, in which the irregular federate guards, not finding among the soldiers that readiness to join them which they expected, but being met with determination, soon gave way before the regular troops, and fled into Paris. Aroused by this defeat, and instructed by experience as to the strength the government now possessed (for the national authorities at Versailles had during the occurrence of the events just related diligently made preparations on their side, and were bringing together an army of 150,000 men, soon placed under the command of MacMahon), the commune leaders instantly prepared to renew the fight. Nearly the whole force in

the city was brought together during the evening and night following, and at dawn of the next day (April 3) nearly 90,000 men, divided into three columns, took the field. The centre column, under Bergeret, was to advance in the direction of Meudon, under cover of the southern forts in the possession of the commune; while the left, under Eudes, was to approach Versailles by way of Vaugirard, Montrouge, and Châtillon; and the right, under Duval, pressing forward from the Rond-Point de Courbevoie, was to pass directly under the guns of Mont Valérien (which the communist leaders were led by rumors and appearances to believe evacuated), and advance upon Nanterre and Rueil. The advance of the three divisions was interrupted almost simultaneously in their three directions of march by the national troops. Bergeret's column was met by a division of the regulars at Meudon, and driven back; the left, under Eudes, encountered a corps of marines and sailors temporarily constituting a portion of the national army, and was compelled to retreat after a fierce conflict. The column under Duval met with the most disastrous fate of all. As it passed directly before Mont Valérien, the commander of the fort, to keep up the delusion with regard to its evacuation, reserved his fire altogether until the column had continued its march so far as to bring the main body of the troops within the closest range. Then he began a merciless cannonade, which nearly annihilated the whole centre of the division. That part which had passed on saw itself cut off, and the troops in the rear fled in a panic. Duval was taken prisoner and shot. Gustave Flourens, who was among the troops cut off, succeeded, amid the flight of his soldiers, in gaining a hiding place in a little house not far from Rueil. He was discovered, however, by gendarmes, and after a desperate resistance was struck down and killed by the blow of a sabre, the commune losing in him probably the most brilliant of its leaders. Immediately after the defeat Gens. Eudes and Bergeret were superseded, and Cluseret was intrusted with the whole management of military affairs, under the title of "delegate for war." On the morning of the 4th he himself took command of the communist troops, and some attempts were made to retrieve the disasters of the day before, especially to regain the heights of Châtillon, which the insurgents had abandoned after their defeat; but they were unsuccessful. These reverses caused violent dissensions among the members of the commune. Assi, accused of having contributed to them, was arrested; and later, Bergeret's place in the army was taken by a Pole, now first becoming prominent in the insurrection, Ladislas Dombrowski, who was also made commandant of Paris. Other changes were brought about among the insurgent leaders, and with them came some decrees and acts of the commune which seemed like the beginning of another reign of terror. Gen. Cluseret issued orders directing that every man from 17 to 40 must enter the service, and that those disobeying this command would be summarily dealt with. Requisitions were made upon churches and theological and public institutions having property in the city. Several rich men were accused of disloyalty to the commune, and their possessions confiscated. The archbishop of Paris, Mgr. Darboy, and a number of other ecclesiastics and prominent persons, were arrested and held as hostages for communist prisoners in the hands of the national troops. A decree was issued wherein it was stated that the authorities at Versailles had transgressed the rules of civilized warfare, having shot prisoners in their hands; and that the commune would thereafter retaliate for all such cases. A commission (*jury d'accusation*) to decide upon these matters, upon the fate of all prisoners of war, and upon the punishment of any persons convicted of treasonable connection with the Versaillists, was immediately instituted; and the decree established the further rule that three hostages, chosen by lot, should be put to death in retaliation for each prisoner executed by the enemy. Searches for concealed arms not given up to the communist troops were conducted all over the city; men suspected of being *réfractaires* (those disobeying the order compelling them to serve) were arrested wherever found; and houses were everywhere entered, ostensibly in quest of them.—Meanwhile the national authorities, who had up to the beginning of the month adopted an altogether defensive policy, while strengthening and organizing their own army, had at last begun the most determined offensive operations against the city on the morning of April 7. Marshal MacMahon was in chief command of their forces; Gen. Ladmirault commanded under him on the side toward Mont Valérien, and Gen. Cissey at Châtillon. Early in the day the guns of Mont Valérien opened on the village of Neuilly and its bridges, which were regarded as a key to the defence of Paris on that side, and were held by the insurgents. Under cover of the cannonade the government divisions advanced and attacked the communist troops. A fierce conflict followed, in which the position was taken by the Versailles soldiers after a desperate defence; but later in the day it was again lost, and the night of the 7th found it still held by the insurgents. The next day the fight was renewed, ending at last in the victory of the national army. Formidable batteries were erected on the ground thus gained, and the guns of these, with those of Mont Valérien, were turned at once against the Maillot gate and the neighborhood of the Arc de Triomphe. The conflict continued until the short period of quiet on the 9th and 10th, without great successes for either party. On the 11th the insurgents won a decided victory by repulsing a night attack of the national troops on the forts at the south of the city, and especially on

Fort Issy. For many days after this the artillery fire on both sides was constant, being particularly severe in the neighborhood of the Maillot gate; but the infantry battles were infrequent and indecisive. Several further attempts made to storm or surprise the insurgents' forts entirely failed, and though the national army on the whole made a steady but very slow advance, the communists lost no important points until the 17th. On that day Col. Davoust of the national army captured the château de Bécon, commanding the positions of Courbevoie and Asnières; and on the 18th the commune's troops were driven from the village of Bois-Colombes, and again from Gennevilliers. On the 19th they were forced back across the Seine.—During all this time events of various importance had occurred in the city, where the principal power was now in the hands of Cluseret, the delegate for war, who became an actual member of the governing body through the supplementary elections, held to fill vacancies, on April 16. A soldier of restless energy and quick decision, he put aside the sentimentalities of the commune leaders, which had led them to intrust the conduct of important affairs to men whose sole merit consisted in their zeal for the cause, and, ruling with the greatest severity over all within his department, he introduced a new military system. He formed a general staff consisting of Rossel, a brilliant young engineer who now begins to appear prominently in the history of the commune, Col. Henry, Col. Razoua, and others having really serviceable military knowledge; he organized the troops, and to his good training and that of Dombrowski must be attributed much of the spirit and skill shown in the defence of the southern forts. The commune's conduct of affairs within the city retained its former features. On April 5 a decree had suppressed, among the papers hostile to the new régime, the *Journal des Débats*, *Constitutionnel*, *Paris-Journal*, and *Liberté;* later decrees suspended the publication of the *Siècle*, *Temps*, *Soir*, *Cloche*, *Opinion Nationale*, and *Bien Public*. On the 12th a proclamation announced the determination of the commune to demolish the column Vendôme. Requisitions were constantly made; arrests were frequent; and among the executions was that of Girot, the commander of a battalion, for refusal to march against the enemy. Dissensions among the members of the commune were continuous; and what with the distress among the people, the lack of aid from the rest of France, and the gradual loss of ground to the national troops, the situation daily became more serious. In the midst of this unfavorable state of affairs the commune published on April 19 its official "programme," long before proposed. It was a document of considerable length, but announced nothing new, and repeated in general terms what had already been made known in previous proclamations concerning the desired self-government of Paris, the decentralization of France, &c.—On April 25 attention was again concentrated on the military operations, by the proclamation of M. Thiers declaring that a great and final attack on Paris would now be begun, the government being satisfied of the uselessness of further attempts at reconciliation, and having determined to devote its energies to obtaining possession of the city. Immediately there began a vigorous cannonade of the southern forts, and a simultaneous advance of the national troops on the western side of the defences. The fire directed against Forts Issy and Vanves principally proceeded from the second parallel erected by the Germans during their siege, and now taken possession of and refitted by MacMahon. Pressing forward from this, he took the village of Les Molineaux, and thus established a position only a short distance from the walls of Fort Issy. On the night of April 29 he further succeeded in capturing the castle of Issy; and from all these advantageous points he was enabled to concentrate upon the fort an almost insupportable fire, which reduced it nearly to a ruin within the next three days. About 1 o'clock on the morning of the 30th a panic seized its garrison, and, refusing longer to defend it or obey orders in the midst of such an overwhelming attack, all but a few soldiers fled from their posts, leaving the batteries entirely silent. This defeat was attended in Paris with the same consequences that had followed the reverses a month before. The popular excitement and the clamor of soldiers and officers demanded a victim, and this time Cluseret was selected. By a brief decree issued on May 1 he was removed from office and placed under arrest, and Col. Rossel was appointed delegate for war in his place. But Issy was not yet so irreclaimably lost as it seemed. It had been deeply mined; the Versailles troops, knowing this, feared to enter it, and it was again taken possession of by a corps of insurgent volunteers. Taking advantage of the speedy arrival of reënforcements, these made a sortie, and succeeded in driving the nationals from the castle of Issy and the village. The tide of success seemed about to turn when, following the plans of Gen. Cissey, the Versailles troops executed a series of well conceived manœuvres, took first the village, then the castle, and finally occupied the fort on May 9, without a serious conflict. Issy lost, the communists found the key to the whole position on the S. W. side of the city in the hands of the enemy. Point after point fell into their possession; a new parallel was established in the southern part of the Bois de Boulogne, within less than 800 yards of the Paris *enceinte;* and a violent attack began on the inmost circle of defences. On the extreme west the national army had also met with successes. The constant fire from Mont Valérien and the many batteries established on that side had gradually beaten down the insurgent de-

fences; and the bombardment of Neuilly and the neighborhood of the Maillot gate had been so incessant as to literally demolish the suburb, and to have rendered necessary long before, for humanity's sake, an armistice of one day (given on April 25) to allow the unarmed inhabitants to go into the city. The substitution of Rossel for Cluseret availed nothing; the new delegate for war, when he had held office less than ten days, handed in his resignation, escaped from the arrest in which he was at once placed, and disappeared. Undoubtedly an able and earnest man, he was still unable to control the confusion of conflicting elements over which he was expected to rule. The military situation was now a desperate one, nothing but the inner circle of Paris itself remaining to the defenders of the commune. The governing body at the hôtel de ville were compelled to have recourse to the most extreme measures. Their finances, managed successively by Varlin and the much abler Jourde, were in a precarious condition, their forces were disorganized, and they had abandoned all hope of aid from without. They forced from the bank of France repeated advances of money, and compelled the leading railway companies to pay them 2,000,000 francs; but the constant payments to their troops, &c., made their expenditures far exceed their receipts. Few skilful officers remained among the commanders of the army, and whole battalions were without chiefs to lead them. Dombrowski, it is true, showed the greatest bravery and energy; but, with discouraged and ill-disciplined troops (he himself called them *incapables*), he could not succeed in the repeated efforts he made to restore the fortunes of the commune. The whole state of internal as well as military affairs had changed. While no delegate for war had been appointed to succeed Rossel, and the conduct of the defence was left to a committee headed by Delescluze, to Dombrowski as commander-in-chief, and to the Italian officer La Cecilia as commandant of the principal fortifications, the management of matters within the city had been given over to a committee of public safety, created by the commune about May 1, and endowed with almost dictatorial powers. Its first members were Antoine Arnaud, Léo Meillet, Ranvier, Félix Pyat, and Charles Gérardin. Under the rule of this body those acts began which were the preludes to the last days of the insurgent rule. On May 10 the committee decreed the demolition of the house of M. Thiers, an order which was carried into effect without delay. On May 16, late in the afternoon, the column Vendôme, the destruction of which had been commanded long before, was overthrown under the direction of the painter Courbet, in the presence of a great multitude of people. The insurgents seemed to be seized with a fury hardly less than madness. The desperate straits in which they found themselves called forth the most bitter hatred against the Versailles government. Popular orators harangued the crowds in the streets and in the great republican clubs, inciting them to renewed efforts and to a brave resistance. Bands of women, as in the days of the old French revolution, marched through the streets, armed, and exciting the people to vengeance upon "the assassins of Versailles." There was even a large and violent political club composed of women. The hatred against the government was carried to great extremes. The explosion of a large cartridge factory in the avenue Rapp was attributed to government agents, and extravagant rumors were circulated as to the barbarities of the Versailles troops.—The end of the defence now rapidly approached. The treaty with the Germans had been signed, and, its foreign relations thus settled for the time, the national government concentrated every energy upon the prosecution of the siege. On May 14 Fort Vanves was captured; Fort Montrouge was almost at the same time abandoned; and the earthwork constructed behind them by Dombrowski proved entirely useless after the forts themselves were in the enemy's hands. The general's attempted sorties were rendered unsuccessful by the refusal of the majority of his now disheartened troops to go far beyond the walls; and the sappers of the national army were thus suffered to carry their works close up under the enceinte. At the gates of Auteuil, Passy, and Point-du-Jour the fortifications were nearly demolished by the constant fire against them. Dombrowski's headquarters near the gate de la Muette became entirely untenable. In this state of affairs, when the moment of giving up the defence of the southwestern enceinte could not be far off, the general determined to retire to a second series of works which should be constructed a short distance in his rear, and by which he hoped to hold in check the national army, even after the capture of the outer fortifications. His plan was skilfully laid, and, had it been carried out as he intended, might have greatly prolonged the struggle. The movement of the troops to the new line of defence was fixed for Sunday, May 21. As projected, it should have been made gradually, so that neither the old line nor the new should be left entirely unprotected until the actual moment for the retreat of the last company from the outer works. But through unskilful management the battalions all retired at once, and for a time, at the middle of the afternoon, the enceinte was absolutely without a guard. Outside, the Versailles troops continued their attack; when suddenly, in a moment of quiet, they were surprised by the appearance of a man upon the wall, waving a white handkerchief, and apparently signalling for an interview. This was Jules Ducatel, a citizen opposed to the commune, who thus sought to give the national officers information as to the true position of the defence. The condition of the enceinte was ascertained, the Versailles troops

pushed forward, and by the end of the afternoon the national army began to enter the city by the St. Cloud gate. A large body of men took possession of the interior of the fortifications, extended along the walls, opened the other southwestern gates to their fellows, occupied without resistance the interior line of works erected by Dombrowski, and drove the few communist soldiers already in their new positions there back to a second series of defences prepared still further from the outer circle. By midnight more than 75,000 national soldiers were within the enceinte. A column of infantry under Col. Piquemal took the barricade protecting the bridge of Grenelle, and surprised and captured troops on the Trocadéro. So rapid were the movements of the national forces that the insurgents at work on a battery at the Arc de Triomphe were similarly surprised and driven from their works, which were at once occupied and used against the batteries at the foot of the Champs Élysées, which were still in the power of the communists. Gen. Cissey took possession of the greater part of the district of Vaugirard and the Champ de Mars, and at once secured himself in the position. With the dawn of Monday morning the more distant quarters of Paris learned with surprise that the Versailles troops were in possession of a large portion of the city. But the victory was by no means won. In the quarters of the capital where the commune was strongest the insurgents thronged to the barricades, prepared for a last desperate resistance. Though it is true that many who would willingly have yielded were forced to this last defence, there was still a great body of men who rallied loyally for the cause to which they had shown such hearty devotion, and the fights of the last five days of the commune's existence saw instances of fidelity to it such as only the most sincere conviction could have called forth from its followers, whether deluded or intelligent. Hurriedly organizing their troops and planning their defence, the leaders turned all their available force to the erection of barricades in every part of the city still in their possession. Proclamations were posted on the walls, inciting the citizens to fight to the last, and officers rode through the streets calling upon the people to make a supreme effort for the sake of their liberties. These appeals met with little response in the wealthier quarters of Paris, where the Versailles troops were greeted with every sign of welcome, but produced the greatest effect in the regions which were the insurgent strongholds, where even women and children fought at the barricades with an energy and fury equal to that of the men. The operations of the national army went steadily on during Monday and Tuesday. Following a systematic plan by which it was designed to advance simultaneously on both sides of the Seine, to take possession of the important strategic points along the outskirts of the city, and thus to form an almost unbroken cordon which could be gradually narrowed until the whole body of the insurgents should be exterminated or taken, the troops were divided into five columns. One of these, forming the right wing and commanded by Cissey, was to operate on the left bank of the Seine, pressing on from the western part of the city toward the quartier Latin; two others, under Vinoy and Douay, were to pursue a course through the centre of the city; and the remaining two, under Clinchant and Ladmirault, were to pass over the hardest ground of all, making their way directly through Montmartre and the portion of the city lying beyond it. To begin the advance of this last named division, it was first of all necessary to take possession of the plateau of Montmartre itself. On Tuesday morning, the 23d, the attack was begun. Many of the leading points around it were gained without difficulty; but for hours a strong and well defended barricade in the rue Lepic kept up a formidable resistance, and it was noon when it was finally carried by a storming party after a desperate conflict. The further defence was slight, and by 2 o'clock the height was in the possession of the national troops. There remained only the place Pigalle, the very cradle of the insurrection, which still refused to yield. Dombrowski commanded its barricade, and under his direction it maintained for two hours a most desperate defence, only ending when the communist leader fell, mortally wounded. By night the whole of this chief communist stronghold was won. On the same day (Tuesday) the division on the left bank of the Seine had overcome one barricade after another, the insurgents defending themselves with scarcely less desperate valor than at Montmartre, and, after a day of the most violent conflict, had possessed themselves of the greater part of the 14th arrondissement, and taken the positions most important for further movements, by which it was intended to partially surround and press in upon the quartier St. Germain. The centre column, advancing on the points held by the insurgents near the middle of Paris—the barricades in the place de la Concorde, near the Tuileries, in the place Vendôme, and elsewhere in the best known portion of the city—encountered everywhere the same furious resistance as in the other quarters. The place Vendôme was only taken by an overwhelming assault made at the same time on both sides, from the rue de la Paix and the rue de Castiglione. One by one the barricades in the boulevard Malesherbes and the boulevard Haussmann were taken; the neighborhood of the Grand Opera, which was strongly defended, followed after a desperate conflict at the northern end of the rue Halévy. The great barracks of Bonne Nouvelle were also captured by Gen. Ladmirault. On Wednesday morning the Bourse was taken; and the centre column was in possession of the whole surrounding quarter,

and prepared to press on with the divisions of the right and left, advancing and gradually concentrating their forces in the direction of the east of Paris, toward the last important strongholds of the commune, at the hôtel de ville and the château d'Eau.—Meanwhile the insurgents, gradually falling back, had recourse to that method of combined defence and revenge which gave the last days of this insurrection a terrible feature unknown to any previous revolution or civil war, however desperate. Organized incendiarism began, and fires broke out in every quarter of Paris. On the bodies of dead insurgents were found orders directing the burning of whole districts, and others directing the destruction of public buildings. All through Tuesday smaller fires had been set; and now, on Wednesday morning, just as the preparations we have noticed were complete, the Tuileries was discovered to be in flames; and hardly was this known before the Palais Royal, a whole side of the rue Royale, and then the distant hôtel de ville itself, were found to be burning also. A panic spread through the city, among the national troops as well as the people; extravagant rumors as to the intended destruction of all Paris by fires kindled with petroleum spread abroad; and now began a day perhaps the most terrible ever seen in the French capital since the massacre of St. Bartholomew. The national troops, already greatly embittered by the obstinate resistance of the commune, and now excited beyond control by the attempt of the insurgents to render their victory useless, and, as it seemed, to destroy the city, began a series of arrests and executions which soon passed all bounds of even apparent justice, and became a slaughter of all who chanced to fall under the slightest suspicion. It was only necessary that a man or woman should be pointed at as *pétroleur* or *pétroleuse;* they were shot down without inquiry or mercy. Houses were searched and those hidden in them were brought into the streets and killed. Many entirely innocent shared the fate of the leaders like Vermorel and Rigault, both of whom fell by these summary executions. A court martial was established in the centre of the city, but even for those who were brought before it there was in most cases only a hurried form of trial. New fires were continually lighted, either by concealed incendiaries, of whom many were taken with the implements for the work in their hands, or by petroleum bombs from the barricades and the districts still in possession of the communists. During this week of conflagrations there were consumed or partially burned, besides a great number of private houses, the palais de justice, the prefecture of police, the palace of the legion of honor, the theatre of the Porte St. Martin, the *grenier d'abondance*, several churches, many large mercantile establishments and minor public buildings; all this besides the more important conflagrations at the hôtel de ville, the Tuileries, and the Louvre. As though the events we have related were not enough to make this day (the 24th) sufficiently terrible, there occurred before its end a massacre which has left the darkest stain on the career of the commune. It has already been stated that the archbishop of Paris and numerous other prominent men had been arrested and confined as hostages for communists in the hands of the national troops. They were now in the prison of La Roquette. In accordance with an order of the commune, they were taken from their cells at 8 o'clock on Wednesday evening, and shot by a file of soldiers in the courtyard of the prison.—During the whole of Wednesday, in spite of the distraction caused by the fires, the troops had steadily continued the manœuvres by which they were gradually closing around the last insurgent strongholds. Around the burning hôtel de ville the communists contested every step of advance with desperate bravery. It was late on Wednesday night before the building, then in flames in four places, was at last abandoned. On the left bank of the Seine the resistance was still more obstinate, and it was only on Thursday afternoon that the Versailles soldiers succeeded in driving the insurgents from their last strong position on the Buttes-aux-Cailles, after the bloodiest contest since the entry into the city. Still fighting, the communists fell back to the manufactory of the Gobelins, which they set on fire. Here was their last desperate defence on this side of the river. Prisoners in their hands were forced to man the barricades, and afterward were shot down after freedom had been scoffingly promised them. After a violent struggle the Versailles troops gained possession of the whole district, and with it of the last contested spot on the left bank. Forts Bicêtre and Ivry, the only fortresses still held by the commune, were also taken on Thursday. On the right bank the troops were pressing upon the faubourg St. Antoine, and after a hard struggle the place de la Bastille was taken on Friday, and the insurgents of the district forced back to the cemetery of Père la Chaise. On the right bank, too, the château d'Eau, the chief defence of the quarter of Belleville, remained. Throughout Thursday and till Friday morning it was still untaken, and it was defended with a valor befitting its importance as one of the final strongholds. At last the insurgents gradually gave way, and, still fighting, retreated eastward through the streets toward the Buttes de Chaumont, where they had a formidable battery. The quarter of Belleville showed itself the firmest in resistance and the last to yield of all. Every point was fiercely contested as the fight went on, and the Versailles troops forced their way only step by step. Friday night came, and the quarter was still in the communists' power, though the national army, forming now almost a half circle, pressed in upon it, and the guns of their bat-

teries poured a constant and heavy fire into it, to which the battery at the Buttes de Chaumont could not make an adequate reply. An interval of quiet about midnight formed a lull before the final struggle. On Saturday, May 27, the fight was begun early in the morning, before the last two places in which the communists still maintained a strong position, the Buttes de Chaumont and the cemetery of Père la Chaise. There were untaken barricades, too, in the faubourg du Temple and the rue d'Angoulême. The conflict continued fiercely all day, point after point being taken, and it was after 7 at night when Gen. Vinoy's column took the cemetery by storm; and the battery on the summit of the Buttes held out until the early morning of Sunday, but was captured at last. In the faubourg du Temple one barricade still fired upon the national troops after the insurrection had been crushed at every other point. In spite of constant attacks, it still held out on Sunday noon. At last the insurgents were driven from it, and the Versailles soldiers, charging over its rampart, found among the dead the body of Delescluze, who had thus fought out the struggle to its end. At 5 o'clock on Sunday afternoon the firing had ceased throughout the city, and a notice from Marshal MacMahon was posted on the walls, announcing that the civil war was over. Nearly 20,000 prisoners were in the hands of the government; the dead were scattered through half the streets of Paris, and the hospitals were crowded with those of both sides wounded at the barricades. Such of the leaders as were still living and had not escaped (and among them, to speak only of those yet unmentioned in this sketch, were the half-crazy Lullier, the sanguinary Ferré, and Urbain) were imprisoned to await the sentence of the court martial held later at Versailles. The great majority of the common prisoners were set free soon after the fall of the commune; a large number were executed at Satory or transported to the penal colonies. The restoration of the injured buildings of Paris was begun at once. The adherents of the insurrection disappeared as if by magic, and the future measures of the national government were carried out in perfect quiet.—See Beaumont-Vassy's *Histoire authentique de la commune de Paris* (Paris, 1871); Moriac's *Paris sous la commune* (1871); Frédéric Lock, *La commune, deuxième siége de Paris* (1871); Clère, *Les hommes de la commune* (1871); Fetridge, "The Rise and Fall of the Paris Commune in 1871" (New York, 1871); *L'Insurrection du* 18 *Mars* (*extraits des dépositions recueillies par la commission d'enquête*), by Edmond Villetard (Paris, 1872); Jules Claretie's *Histoire de la révolution de* 1870–'71 (published in numbers, 1871–'2); Harrison's "Apology for the Commune" (essays published in the "Fortnightly Review" for August, 1871). The official accounts of the trials of the communist leaders, begun on Aug. 7, 1871, were published from time to time during the sitting of the court martial, and form a complete record of its proceedings.

COMMUNISM. See Socialism.

COMNENUS, a Byzantine family, of Italian origin, the members of which played a prominent part in the history of the Eastern empire from the middle of the 11th to the middle of the 15th century. To this family belonged six emperors of the East (from 1057 to 1185), viz.: Isaac I., Alexis I., John II., Manuel I., Alexis II., and Andronicus I. In 1204 one of its members conquered Trebizond and a portion of Asia Minor, and founded the empire of Trebizond, which continued in the hands of his descendants till 1461, when it was conquered by the Turks, David Comnenus, the last of the race, being put to death in the following year with all his family by command of Mohammed II. Other members of this family were noted as statesmen, generals, and authors. Attempts have been made to trace the descent of the Bonapartes from a Comnenus who settled in Corsica, but the pedigree has not been satisfactorily made out.

COMO. I. A province of Italy, in Lombardy, bounded N. by Switzerland and S. by Milan; area, 1,048 sq. m.; pop. in 1872, 477,642. It is traversed by branches of the Lepontine and Rhætian Alps and other mountain ridges. It is dotted with lakes, and watered by several rivers, of which the Adda and Ticino are most important. It produces corn, wine, fruit, and silk, and rears horses, mules, and cattle; contains mines of lead, iron, and copper, and quarries of white marble; and possesses manufactories of cloth and woollen and silk goods, firearms, paper, soap, candles, &c. The people are industrious, and there is at least one elementary school in each commune. Famous in ancient times as lapidaries and masons, many of the inhabitants still follow the same pursuits, and others travel about supporting themselves by the sale of barometers, looking-glasses, and kindred articles manufactured in the town of Como. The province, with the rest of Lombardy, was ceded by Austria to Italy in 1859. **II.** A city (anc. *Comum*), capital of the province, situated at the S. end of the lake of Como, 24 m. N. N. W. of Milan; pop. in 1872, 24,350. It is connected by steamboat with Camerlata, about a mile distant, and thence by railway with Milan. It has many suburbs along the lake, of which the most extensive are Vico on the west, abounding with villas, of which the villa Raimondi or Odescalchi is the most splendid, and St. Agostino, the manufacturing suburb. It is the see of a bishop, and has a splendid marble cathedral, begun in 1396; a remarkable church of still greater antiquity dedicated to St. Fedele; a town hall, completed in 1213; and a magnificent theatre built in 1813. There are several institutions of charity and learning, including three gymnasia, and a lyceum with a library of 15,000 volumes and a reading room. On a hill south of the city is the lofty tower of the Bara-

dello. Here Napoleone della Torre, having been taken prisoner by his rival Ottone Visconti, Jan. 21, 1277, was shut up in an iron cage, in which he died by his own hands after 19 months of painful confinement. Pliny the Younger (and perhaps also the Elder), Volta (a square, adorned with his statue by Marchesi, bears his name), and Innocent XI. were natives of this town. It has manufactures of silks, woollens, cotton, yarn, and soap. In former times the silk trade of Como vied with that of Lyons. After the revolution of February, 1848, the people of Como were among the first to shake off the yoke of the Austrians, and drove their troops from the city. **III. Lake of** (Ital. *Lago di Como;* anc. *Lacus Larius*), a picturesque and tortuous sheet of water, full of promontories, gulfs, and little bays. At its northern extremity a narrow channel unites it with a kind of distinct lake, called Laghetto, which receives the river Maira. Thence it extends S. W. and S. for about 15 m., and at Bellagio divides into two branches. The W. branch retains the name of Como, and is 18 m. long. The other is named Lago di Lecco, from the town of that name; its length is about 12 m. The river Adda, which enters the lake at its junction with the Laghetto, leaves it at Lecco. The width of the main lake in most places is not more than 1 or 2 m., but just above the separation of the two branches it is 3 m. across. The banks are formed of precipitous mountains from 2,000 to 3,000 ft. high. A mild and genial climate, a fertile soil, profusion of fruits and vegetables, and prosperous villages scattered over the country, combine to render its banks one of the most delightful regions of Italy. Among the handsome mansions which

Como.

line the shores are the villa Melzi, the villa Ciani, formerly d'Este, long the residence of Queen Caroline of England, the villa Carlotta, formerly Sommariva, which contains a fine museum, and the villa called Pliniana, on account of the intermittent spring described both by the elder and younger Pliny, and still exhibiting the same phenomena.

COMONFORT, Ygnacio, a Mexican statesman, born in Puebla, March 12, 1812, killed near San Luis Potosí, Nov. 13, 1863. He entered the Jesuit college at Puebla in 1826, became a captain of cavalry in 1832, and took part in the revolution of that year. In 1834 he was made prefect and military governor of the district of Tlapa; in 1842 he was elected member of the national congress, but this was soon dissolved by Santa Anna, and Comonfort resumed his functions in Tlapa. In 1846 he was reëlected to congress, but this congress was dissolved by Paredes, and the liberals instigated the revolution of August, 1846, in which Comonfort took a conspicuous part. Appointed third alcalde of the capital, and afterward prefect of western Mexico, he relinquished these posts to engage in the war with the United States; and on Santa Anna's dissolving the army and leaving the capital open for the Americans, Comonfort commenced organizing guerillas in the west, when he was summoned to the congress of Querétaro, where a treaty of peace was concluded with the United States. He was now chosen senator by his native state, and served in this capacity till 1851. In 1852–'3 he was the representative in congress of the state of Guerrero, and acted as custom-house director of Acapulco and other places until Santa Anna's return to power, when he was dismissed. He now joined Alvarez, and proclaimed the plan of Ayutla, March 11, 1854. Repairing to New York, he raised funds to carry on the war, and on his return took a prominent part in the

campaign, at the end of which, in 1855, Santa Anna was compelled to abdicate. Alvarez assumed the supreme government, but soon delegated his authority to Comonfort, who became provisional president, Dec. 11, 1855. He met with strenuous opposition on the part of the clergy, the army, and the large body of the conservative party. The junta of Zacapoastla declared itself on Dec. 19 against the president, and a little later the seat of revolution was transferred to the city of Puebla. Over 5,000 men assembled there in February, 1856. Comonfort marched against the insurgents, and having forced them to surrender, he promulgated on March 31 a decree ordering the confiscation of the property of the church, which was followed on June 28 by another decree forbidding the clergy to hold landed estate. The clergy labored to undermine the government, and revolts broke out in Puebla in October, 1856, and afterward in San Luis and other places; and although they were quelled, the country remained in a distracted condition. The congress which assembled Feb. 5, 1857, drew up a new constitution, which was promulgated March 11. This vested the legislative power and the control over religious and military affairs exclusively in congress. Comonfort was eventually constrained, in October, 1857, to apply for extraordinary powers. These were granted by congress Nov. 4, and he was proclaimed constitutional president Dec. 1. Opposed by the clergy and the army, he could only depend upon the brigade of Gen. Zuloaga, which was attached to him personally. By a pronunciamiento at Tacubaya, Dec. 17, this brigade declared itself against the new constitution, and appointed Comonfort chief of a new government; but by a new pronunciamiento of Jan. 11, 1858, they discarded him altogether, and the insurrection which broke out on that day in the capital led to a bloody struggle of several days. Appointing Juarez, president of the supreme court, provisional president, Comonfort vainly attempted to regain his authority by force of arms. On the morning of Jan. 21 the capital was in the hands of the insurgents. The house of representatives, convoked on the same day by Zuloaga, appointed that general provisional president, while Juarez convened a congress at Guanajuato to guard the rights of Comonfort. The latter in the mean time, deserted by his soldiers, took his departure from Mexico in February, 1858, and repaired to the United States, and afterward went to France. Juarez, having triumphed over Miramon and the church party, was chosen president in 1861. Shortly after the close of 1861 Comonfort returned to Mexico, and offered his services to Juarez, by whom he was appointed commander of the army. He was on his way from Mexico to San Luis Potosí when he was murdered by banditti.

COMORIN, Cape. See Cape Comorin.

COMORN, or **Komorn** (Hun., *Komárom*). **I.** A county of Hungary, on both sides of the Danube, and watered by its affluents the Waag and the Neutra; area, 1,145 sq. m.; pop. in 1870, 143,090, almost all Magyars. It is level and exceedingly fertile in its northern portions; the southern are hilly or mountainous. The district around Neszmély, near the S. bank of the Danube, produces the excellent wine of that name. Among the principal towns is Dotis (Hun. *Tata*). **II.** A fortified town, capital of the county, situated on the eastern extremity of the island of Schütt, at the junction of the Danube and the Waag, 85 m. S. E. of Vienna; pop. in 1870, 12,256. Among the principal buildings are four Roman Catholic and two Protestant churches, a Greek church, and a synagogue. The town contains several learned and charitable institutions, a cannon foundery, and a manufactory of firearms. The fortress, defended by extensive works on both sides of the Danube, was founded by Matthias Corvinus in the second half of the 15th century, and has been rendered one of the strongest places in the world by the additional fortifications erected since 1805. Its impregnability was tested in the revolution of 1848–'9, when it withstood a long siege and bombardment under Mack, Guyon, and Klapka, and finally came into the possession of the Austrians by a voluntary capitulation (Sept. 27, 1849). The treasury of the national bank was deposited here when the Prussians threatened Vienna in 1866.

COMORO ISLES, or **Comoros,** a group of high volcanic islands in the Mozambique channel, between Africa and the N. W. coast of Madagascar, consisting of the islands of Angaziya or Great Comoro, Anzooan or Johanna, Mayotta, and Mohilla, lying between lat. 11° and 13° S., and lon. 43° and 45° 30′ E.; area, 1,050 sq. m.; pop. estimated at from 50,000 to 80,000. They are fertile in most of the productions of the tropics. The rivers abound in fish, and vast herds of cattle range the meadows. Cocoanuts, cocoanut oil, and tortoise shell are the chief exports. Sugar has recently been cultivated with success, and now forms an article of export. The inhabitants are Arabs and negroes, who generally profess Mohammedanism, but fetishism is practised to some extent. Coarse cloths, jewelry, and firearms are manufactured. The Comoros are governed by sultans, one of whom resides in nearly every town. The island of Mayotta was ceded to France in 1841, and the cession was confirmed in 1845. Comoro, the largest island, is 30 m. long and 12 m. broad. It has a large town on the E. side, but is seldom visited by Europeans, and contains no spring water. The drink of the inhabitants is the milk of the cocoanut.

COMPARATIVE ANATOMY, the science which treats of the structure and relations of organs in the various branches of the animal kingdom, without a knowledge of which it is impossible to understand the beautifully progressive development of organization; necessary even for the full comprehension of the uses of many parts of the human body, which, apparently

rudimentary and useless in man, are highly developed in other animals. This science is also the basis of physiology and the natural classification of animals. On a subject so vast as this, comprehending the whole range of animal life, it will be impossible here to give anything but a sketch; selecting a few only of the more important functions, instead of attempting an exhaustive treatment of the science. In order to simplify the subject, and to make this article especially referable to human anatomy, the whole division of the invertebrata will be left out, for consideration under its separate branches and classes.—*Skeleton.* In the vertebrata, the most striking character is the great preponderance of the nervous system, which impresses peculiar forms on the skeleton, and corresponding arrangements on the vital organs; everything in their structure seems destined for the protection and suitable exercise of the nervous system; this is less observable in the lower forms, but in all the nervous centres are largely increased and collected together, compared with the invertebrata, and the principal portions enclosed in the bony canal of the spine and skull, to which the limbs with their muscles are attached; their bony fabric, therefore, is properly called neuroskeleton, to distinguish it from the external or dermoskeleton of invertebrates, the former having a basis of phosphate of lime, the latter chiefly of carbonate of lime. In the lowest vertebrates, as in eels among fishes, and serpents among reptiles, the spinal column and its cranial continuation constitute the principal and essential parts of the skeleton, the development of limbs being secondary; the skull is composed of the same elements as the spine, enclosing the cephalic ganglia and protecting the organs of special sense. The vertebral column is the first rudiment of the skeleton in the human embryo. The bones of fishes are comparatively soft, flexible, and elastic, in the lowest species without division into vertebræ, and in the sharks and rays cartilaginous, resembling the embryonic conditions of higher animals. Having no weight to support from the density of the medium in which they live, and being forced only to propel themselves through the water, which is effected by the lateral movements of the spine, the vertebræ are very numerous, and united by biconcave surfaces enclosing a gelatinous substance which admits of easy motion of one bone on another when the vertically flattened tail strikes the water; in aquatic mammals, as the whales, the tail is flattened horizontally to enable them to rise to the surface to breathe air, which distinguishes them from fishes. The number of vertebræ varies from 25 in *uranoscopus* to more than 200 in sharks, and some are said to have only 13. The lateral surface of the fish is extended by large spinous processes and fin rays on the back, or what may be called the dorsal or abdominal vertebræ, and to these are attached also the ribs when any are present; those which have spines below are called caudal vertebræ, the last being triangular and flattened to support the fin rays of the tail; the dorsal and abdominal fins move only with the spine. Though requiring no chest for respiratory organs, many fishes have ribs, and a few a rudimentary sternum. The cranium in the cartilaginous fishes is very simple, but in the osseous tribes is composed of a great number of pieces whose homologies are not always well determined; the brain cavity forms but a small part of the head, and its component bones are easily recognized as direct continuations of the vertebræ; the bones are thin and united by squamous sutures, which favors extension during growth; the lower jaw and operculum are supported on each side by a series of bones resembling the os quadratum of birds; the hyoid bone is greatly developed, supporting the branchial arches and organs of respiration. The pectoral fins represent the anterior extremities and the ventrals the posterior; the latter are frequently absent; the former are attached to an osseous scapular arch, articulated to the skull; to this are attached an arm, forearm, and numerous carpal or wrist bones, from which the fin rays or fingers spring; the arm remains within the body, only the hand being external, consisting of a large number of fingers with many joints; no animal above fishes has more than five fingers, and some have only one (the middle finger), as the horse. The pectorals of the skates are wing-like, surrounding and even projecting in advance of the head; in the flying fishes they are so long that they serve for a species of flight; they vary in position, being sometimes under the throat and sometimes behind the ventrals; in a few species they are wanting. The posterior limbs, or ventral fins, are not articulated to the spine and do not form a bony arch as in the shoulder, but are suspended to the rib-like iliac bones at a distance between the head and anus varying in different families; in the jugular and thoracic fishes the bones supporting the ventral fins are attached to the arch which sustains the pectorals; there are small bones between the pelvic and the fin rays, which, if any, must represent the femur, tibia, fibula, and tarsus of the higher animals. A singular peculiarity in the skeleton of fishes is its want of symmetry in some genera; in the soles (*pleuronectes*) and flounders (*platessa*), one side is turned upward instead of the back, both eyes are placed on the same side, and the cranial bones are distorted to allow this arrangement of the organs. In most osseous fishes there are many small forked bones interspersed among the muscles, having no connection with the skeleton, serving as points of support to the muscles.—In the amphibia, which constitute a class of animals intermediate between fishes and true reptiles, there is an extraordinary difference of external form and internal structure during the metamorphosis which most of them undergo. In all, the spine con-

sists of dorsal, sacral, and caudal portions; in the frog there are only 8 or 9 vertebræ, in some of the salamanders more than 40, and in the siren 80 or 90; in the higher forms the vertebræ have no ribs, but long transverse processes, and are united by a ball-and-socket joint, with anterior concavity and posterior convexity; in the tadpole and perennibranchiate genera the spine is like that of fishes; in the frog, destitute of a tail, there is no coccyx, but in the salamander the coccygeal vertebræ are as numerous as those of the trunk, forming a powerful swimming organ. The bones of the skull are less numerous and more united than those of fishes; the brain cavity is very small, and the facial bones much developed transversely; the os hyoides undergoes remarkable changes according to the persistence of the branchiæ, as detailed in the article Amphibia; the tailed genera have cartilaginous appendages to the transverse processes, like rudimentary ribs. The scapular arch is well developed, consisting of the usual three bones, which unite to form the glenoid cavity, and in most genera has a distinct breast bone extending beyond the chest both anteriorly and posteriorly; the bones of the arm, forearm, and hand are easily recognized. The posterior extremities in the leaping batrachians consist of a long and cylindrical femur, a tibia and fibula consolidated into one bone, a tarsus and long metatarsus, and five toes; in the aquatic species the limbs are small and feeble, in some rudimentary, or even wanting, the powerful tail serving for rapid locomotion.—In serpents the skeleton is little more than a vertebral column and its ribs; there are no limbs (only the merest rudiments in some), and the motions of creeping, climbing, swimming, and springing are performed entirely by means of the flexible spine and the very numerous ribs; the number of the vertebræ is greater than in any other animals, being sometimes over 300, and their arrangement by ball-and-socket joints allows of very free lateral motion; the ribs, upon which they creep as upon so many feet, like an articulate, extend from the head to the anus, and are attached to no sternum; the bones of the head are very numerous, and movable upon each other; the brain cavity is small. Snakes may be distinguished from lizards without feet by the separate movements of the two halves of the jaws, which allow the remarkable expansion of the mouth necessary to swallow their large prey. In lizards the skeleton is more perfect; in them are seen for the first time cervical vertebræ; they have also distinct dorsals, bearing ribs, lumbar, sacral, and caudal vertebræ, articulated by ball-and-socket joints; also a sternum, scapular and pelvic arch, with very distinct and normally divided limbs in most genera; they have what have been called cervical and abdominal ribs before and behind the true ribs, and the sternum is prolonged nearly to the pubis, giving origin to cartilaginous arches supporting the abdominal viscera, of which the homologues in man are the lineæ transversæ of the rectus abdominis muscles. In the flying dragon, a small lizard, the ribs are elongated and covered with a thin membrane, by means of which the animal sails, like the flying squirrel, from one point to another below, using this membranous expansion as a parachute. In the fossil pterodactyl, a flying lizard, there is a remarkable elongation of one of the anterior fingers, which supports a flying membrane similar to that of the bat. In the rhizodonts, including the crocodiles and the large extinct fossil genera, the skeleton is still further developed, approaching more nearly to the mammalian type, especially in the extremities. The bones of the cranium are firmly united to each other, and there is no lateral movement of the jaws, as in snakes; the brain cavity is small; the whole number of vertebræ is decidedly less, and locomotion is proportionally performed by the feet, though the tail in the aquatic genera is still largely developed and very muscular. In tortoises, the highest reptiles, it would be difficult at first sight to recognize the usual structure of the class, but a closer examination betrays no essential difference. The spine consists of 7 or 8 cervical vertebræ, 8 to 14 dorsal, 3 sacral, and 20 to 30 caudal; the broad flat bones under the scales are a series of ribs, as may be seen by examining their connection with the spine from the inside, and the lower cuirass or plastron is a series of sternal bones, in which the ends of the ribs unite; the aquatic species have these ribs united only in the portions nearest to the spine; this immovable box of ribs and sternum, overlaid with the scales of the dermoskeleton, is admirably adapted to resist pressure. The bones of the skull are firmly united, and form large cavities and fossæ for the protection of the muscles of the jaws; the brain cavity is still small. The anterior limbs are attached to the inside of the chest; the scapula below the viscera, and close to the plastron, is united to the collar bone by suture; the humerus is arched and twisted, the forearm short, broad, and permanently pronated; three rows of carpal bones, metacarpus, and phalanges. In the pelvic arch the ilium and the pubis seem to change places, the latter being broad and flat, and uniting below with the ischium, while the former is long and narrow, and projects backward, the whole pelvis being movable on the spine; the femur presents a trochanter, and has quite a mammalian aspect; the bones of the leg are separate, and nearly equal; the aquatic species have longer and more slender limbs.—In birds the number of vertebræ is quite variable in the different regions of the spine; in the neck, according to Cuvier, from 23 in the swan to 9 in the sparrow; in the back, from 11 in the cassowary and swan to 6 in the bullfinch; in the sacrum, from 20 in the ostrich to 7 in the coot; in the tail, from 9 to 5; these proportions being connected with the habits of the species. Though so very different from the

lower classes, birds differ from each other only slightly in their skeletons; the bones of the neck, back, chest, and extremities are remarkably similar in all; they vary chiefly in the shape and size of their bills, the form of the feet, and the proportions of their bodies. Their bones are white, compact, fragile, and hollow for the introduction of air. The cervical vertebræ are the most numerous; their bodies lock into each other so as to allow a forward motion in the upper and lower ones, and a backward motion in the middle ones; the transverse processes are long, and have rudimentary ribs, especially developed in birds of prey. The bodies of the dorsal vertebræ are short and compressed laterally, and have large transverse processes; they are generally immovable in birds of powerful flight. The sacral vertebræ are firmly united together, and with the pelvis, in order to give support to the superior parts of the body in flight, and a sufficient base for the lower extremities. The bones of the tail are broad and short, penetrated by the spinal cord except the last, which is compressed, supporting the tail feathers and an oil gland. The skull is united into a single box at an early period; the brain cavity is very much larger than in the reptiles and fishes, and is occupied fully by the nervous centre; the brain of a sparrow is 100 times greater than that of a large marine turtle, in proportion to the size of the animals. The most striking characteristic of the class of birds is that the anterior and posterior extremities are entirely dissimilar in appearance and function, though the anatomical structure of the wings and legs is the same. The perfect condition of the chest indicates the energy of the respiratory system, and the consequent muscular activity. The ribs are strong, attached to the sternum in front by bony continuations instead of elastic cartilages, movable only at each end, articulated to the sides of the vertebræ in the flyers, but to the intervertebral cartilages in the runners; in those which require great solidity of the chest for powerful flight, each rib is strengthened by bony splints running obliquely upward and backward to the succeeding bone, to which it is attached by strong ligaments. The sternum is provided with a keel or crest in front for the attachment of the muscles of the wings, large in proportion to the flying power; in the ostrich, which does not use its wings to rise in the air, this bone is flat as in man; in some aquatic birds the breast bone contains several convolutions of the windpipe within its cavity. The shoulder blade is parallel to the spine, long and narrow, at the glenoid cavity articulating with the clavicles and coracoid bones. The coracoid bones, or posterior clavicles, are strong, extending from the glenoid cavity to a transverse groove in the anterior portion of the sternum; these are called the collar bones by some of the older authors. The true clavicles, the "merrythought" or "wishbone," vary considerably in size, being sometimes quite rudimentary, and in other species strong arches reaching the sternum. The wing consists of a humerus, radius, and ulna, carpus and metacarpus of two bones each, a small single-jointed ulnar finger, a two-jointed radial finger, and a rudimentary thumb. Prof. J. Wyman has shown in the *anas acuta*, or pin-tailed duck, an arrangement of the bones and ligaments by which all the segments of the extended wing are retained in a fixed position independently of muscular action, and the flexion or extension of the hand on the forearm when the latter is flexed or extended on the arm; during flexion and extension the radius advances and recedes upon the ulna, carrying with it the upper bone of the carpus, and with this last the hand; when the upper carpal bone, to which the lower is attached firmly, is drawn over the end of the ulna as the radius recedes, the lower is drawn up between the hand and the end of the ulna, maintaining the hand extended, like a wedge, until it is displaced by the reversed action of the radius. ("Proceedings of the Boston Society of Natural History," vol. v., p. 169.) In the lower extremity the iliac bones correspond to the shoulder, the thigh bone to the arm, the leg to the forearm, and the foot to the hand. Though one be covered with feathers and the other bare, the wings and legs present the same analogies that may be traced between the fore and hind legs in all the vertebrata.—*Form.* In the mammalia, or animals bringing forth living young and nourishing them with milk, there is a great variety of form. Man, the horse, the whale, the seal, and the bat, notwithstanding their dissimilar external appearance, exhibit in their skeletons and internal structure homologies which show that they belong to the same class; the whale is nearer to man than to the fish, and the bat is more human than bird-like. The form of the skull varies much in mammals, according to the development of the brain cavity, and the proportions of the face. A direct relation is found to exist between the size of the cranium and face and the intelligence of an animal. In man the cranium, or brain cavity, is directly over the face; and in proportion as the former retreats behind the latter, and as the face is prolonged forward, the animal propensities preponderate over the intelligence. The differences between human crania in this respect early attracted the attention of anatomists, and Camper measured them by what is called the facial angle; this is formed between a line drawn horizontally from the opening of the ear to the upper teeth, and a line drawn vertically from the forehead to the same incisors. In the white races this angle is from 85° to 80°, thence decreasing in the other races as low as 65°. In some of the antique statues this angle is made 90° and in one case 100°, which last never existed unless in disease. In children, the forehead is more prominent than in adults, and their facial angle is usually 90°; this explains their generally pleasing countenances as well

as the diminution of their innocent beauty as age advances. Those animals which have the lowest heads and the longest snouts are always considered the most stupid and gluttonous, as the hog among quadrupeds; as we descend to reptiles and fishes, it has been seen that the jaws constitute almost all the head, and these are known to be the most voracious of creatures, apparently living only to eat; on the contrary, a great degree of intelligence is attributed to the elephant from his well marked forehead, and the perpendicular-visaged owl is made the companion of the goddess of wisdom; though in the last instance these semblances do not depend on any greater development of brain, but are mere bony expansions. Even among men, we instinctively regard him as stupid and sensual whose face is very prominent and whose forehead is receding; the advancement of the forehead toward the line of the face is always understood by artists as representing a noble and elevated character. As we recede from man the brain cavity diminishes, the jaws and nasal fossæ are lengthened, the orbits are directed more externally and are less distinct from the temporal fossæ; the occipital foramen and its two condyles gradually fall behind the middle of the base of the skull, and finally occupy its posterior face, so that the jaws, instead of being at right angles to the spine, become parallel to the axis of the body. The eight cranial bones of man may be recognized in the mammal skull, though they are variously subdivided in the different families, and in some are united together; the two parietals are united in the carnivora, while the frontals remain separate, and the temporal tympanum is divided from the rest of the bone by a suture; in the elephant the frontals and parietals are early united with the other bones into a solid box. Though the skull of the highest apes resembles that of man in shape, the bones are differently connected; the wing of the sphenoid does not reach the parietal and barely touches the frontal, and the temporal suture is serrated rather than squamous. From the position of the occipital foramen it is evident that the head of mammals is not balanced on the spine, but is suspended from the neck and back by the ligamentum nuchæ. The bones of the face differ from the human in the greater number of pieces and in their horizontal extent. In man the upper jaw bones contain all the upper teeth; but in the lower animals the incisors are contained in an intermediate bone, the intermaxillary, a persistence of a separation which may be detected in the human fœtus. The palate bones are small in the carnivora, and large in the rodents; the upper jaw is elongated in all. The peculiarities of the bones forming the orbits will be given under the heads of the different families. No animal but man has a chin; in all below him the anterior arch of the lower jaw is convex vertically and retreating at its lower margin; in the whale it resembles two immense ribs, united at the points, without any ascending branches, the articular surface being directed backward; in the hare and rabbit the coronoid process, to which the elevating muscles are attached, is small, but in the squirrel and rat it is large, and the condyle or articular process is compressed laterally and largest in front; in carnivora the condyle is transverse, and admits only of a hinge-like movement; in the ruminants the flat articular surface allows considerable lateral motion; in cetacea and edentata there is neither ascending ramus nor coronoid process, and the angle formed by the body and ramus is gradually reduced until it becomes on a line with the axis of the jaw; in carnivora, rodents, and ruminants, the two sides of the lower jaw are never firmly united at the symphysis. Many mammals have the head surmounted with horns; that of the rhinoceros belongs to the skin, and is only an assemblage of closely united hairs, but the horns of ruminants have a bony axis springing from the frontal bone. The bony prominence in the giraffe is covered by the skin permanently; in the stags the bony core is at first under the skin, but soon becomes exposed, and after a certain time falls off, to give place to another similar growth; in the ox, sheep, goat, and antelope, the osseous axis grows during life, and never falls, being covered by a sheet of horn, growing by layers; these bony cores generally communicate with the frontal sinuses, and thus receive air into their interior. The species with falling horns have generally only the males thus armed; the reindeer, however, is an exception. The comparative anatomy of the brain has been sufficiently given under the title Brain.—*Nervous System.* The vertebrate nervous system is not homologous with the invertebrate; the spinal cord of the former is enclosed in a vertebral canal, and its vesicular substance is continuous throughout, while the ganglionic chain of the latter is always in the general cavity with the viscera, forms a ring through which the œsophagus passes, and its vesicular substance is frequently interrupted. Though the vertebrate spinal cord cannot be considered as a chain of ganglia, it may be regarded as a series of segments arranged in a linear direction, having a distinct enlargement in many animals at the origin of the spinal nerves, and particularly of those sent to the extremities. The spinal cord of fishes terminates near the end of the spine. Owen says that in typical fishes it gradually tapers to a point in the heterocercal or unequal-tailed species, but swells again into a terminal ganglion in most equal-tailed species; in describing that of the angler (*lophius*), he has evidently fallen into an error in regard to its length, as shown by the researches of Prof. J. Wyman (see "Proceedings of the Boston Society of Natural History," vol. iv., pp. 150, 151); the latter found the cord extending as usual quite near to the tail, where it ended in a ganglion, presenting the striking peculiarity of being sheathed

in a great part of its extent by an immense number of bundles of nervous fibres, of a vastly greater bulk than the cord they surrounded. Where the pectoral fins are much developed, as in the rays and flying fishes, the cord is enlarged at the origins of the nerves; in the torpedo and electrical eel, nerves are freely distributed upon the thin membranous laminæ which constitute the electric apparatus, and act as conductors, if not as generators, of this force. The cord is composed of an external white or tubular portion, and an internal gray or vesicular matter, the reverse being the arrangement in the brain. In the *amphioxus*, the simplest vertebrate, the cord, with its nerves on each side, forms the whole nervous system; but in fishes generally the cerebral ganglia, with the nerves of special sense, constitute a distinct brain. The olfactory lobes, by some considered the representatives of the cerebral hemispheres in man, from which the nerves of smell arise, are well developed, and in the sharks are four instead of two, the usual number. The optic lobes, behind these, homologous with the tubercula quadrigemina, are larger than the other parts of the brain, and are in proportion to the development of the optic nerves which arise from them and the perfection of the sense of sight. In the blind fish of the Mammoth cave of Kentucky (*amblyopsis spelæus*), in which the eyes are rudimentary, there appears to be an exception to this law; though he could detect no optic nerves, Prof. Wyman found the optic lobes of good size, though less than in the allied fishes. Between the olfactory and optic lobes are the true cerebral hemispheres, largest in the sharks; behind the optic lobes is the cerebellum, which comparative anatomy shows to preside over the coördination of the movements, largest in the active sharks. In the perennibranchiate amphibia the brain and nervous system are very much like those of fishes; in the genera which undergo metamorphosis the changes from the fish-like to the reptilian brain are rapid and remarkable, the hemispheres becoming enlarged and the spinal cord shorter as the tail disappears. In frogs, there are found attached to each spinal nerve, before the division into sensory and motor roots, vesicles containing a white, chalky, crystalline substance; from their constant presence, they are considered essential parts of the nervous system; nervous filaments have been traced into the interior of these vesicles; the chalky matter resembles that found in the vestibule of the ear. In true reptiles the brain is more developed and nearly fills the cranial cavity; the hemispheres are increased in size, and the cerebellum is large in proportion to the activity and complexity of the movements; the nerves are large compared with the centres, and the sympathetic system is more closely connected with the blood vessels. In birds the parts of the brain are no longer on the same plane, are larger, more complicated, indicating more intelligence and more activity. In the spinal cord there is an enlargement where the nerves are given off to the wings, and another where those of the legs take their origin; that these are not proportional to muscular force, but rather to sensibility, is shown by the fact that the latter is the larger; though the wings are more muscular, they are, from their feather covering, less sensitive to external impressions than the legs; this is more clearly shown in the mammalian bat, where the enlargement corresponding to the exceedingly sensitive wings is by far the greatest. In mammals the cerebral and cerebellar hemispheres reach their highest development, the former gradually covering over the latter, and the convolutions becoming more numerous and complicated up to man; the commissures more intimately connect their different portions; the spinal cord is larger in proportion to the size of the body, but smaller when compared with the brain; and the sympathetic system is more extensively distributed.— *Organs of Special Sense.* By means of the organs of special sense, placed at the extremities of the cerebro-spinal nerves, and generally near the entrance of the alimentary canal, animals are brought into relation with external objects; an impression communicated to the outer surface is transmitted to the sensorium along the sensory fibres of nerves, and there causes the phenomena of smell, vision, taste, hearing, or general sensation, with their resultant motor acts from the transmission of the nervous influence along the motor fibres; in all the vertebrates there are organs set apart for this purpose, the nose, the eyes, the ears, the tongue, and the skin. The sense of touch, residing in the skin, is the most universally diffused, and is capable of answering most practical purposes of the other special organs; and indeed the senses of taste and hearing seem to be little else than modifications of the sense of touch; the senses of smell and vision depend upon the influence of such delicate changes in the surrounding air that we can hardly comprehend them except through their effects. The skin consists essentially of two layers, the cuticle and the true skin; the surface of the latter is the seat of sensibility, and is provided with numerous papillæ into which the nervous loops enter; the cuticle is made up of nucleated cells, becoming dry externally and falling off in the form of thin flakes. In fishes the body is generally covered with scales, not fit for receiving tactile impressions; some of the siluroids, as the horn-pout, have fleshy barbels attached to the lips, into which nervous filaments may be traced; their skin is lubricated with a viscid mucus poured out through numerous tubes. In the amphibia the skin is soft and yielding, and quite sensitive; it is well known to be in this class an important accessory organ of respiration. In serpents and lizards the tongue and the tail are the principal organs of touch. In birds the tactile organs are the bill, the cere, and vari-

ous appendages in the shape of combs, wattles, bristly hairs, and caruncles; in the swimmers and waders the bills are very sensitive; in the snipe and woodcock, for example, the fifth pair of nerves is freely distributed to the long bill, making it an exceedingly delicate organ for the explorations necessary in their search for food. In mammals, most of which are covered with hair or thick hides, the sense of touch is most acute in the neighborhood of the mouth; the lips of the horse are very sensitive; those of the carnivora and rodents are provided with long whiskers, into which nerves enter, forming exquisite organs of touch; the complicated appendages to the nose of bats, and also their delicate wings, are very sensitive tactile organs. With the exception of the tongue, which is sensitive in all, there is no approach to the perfect development of touch in the human subject until we reach the quadrumana, in which the hand is the chief tactile organ. The fore foot of the ruminant, ending in a hoof, serves only for support and locomotion; in the feline tribes it is in addition prehensile, and to a certain extent tactile; in the monkey the palmar cuticle is thin and sensitive, though the hand is still used in locomotion; in man the sense of touch is very acute in the tips of the fingers, though all parts of the skin are more or less sensitive. The sense of touch may be educated to a degree almost substitutive for the sense of sight; what the bat's wing is naturally, the blind man's fingers may become by education. The sense of taste, even in man, must be considered as principally a modification of the sense of touch; as it is impossible to draw the line between the mucous membrane and the skin, which are also composed of the same elements, and as the sensory branches of the same fifth nerve are distributed to the face, lips, mouth, and tongue, it is naturally inferred that a great part of what is called taste is really touch, applied to a special locality for special purposes, as in the wing of the bat and the tips of the fingers; and some are of opinion that the sense of smell supplies all of taste which is not derived from touch. The papillæ of the tongue are more highly developed than those of the skin, and are scattered over its surface in all parts likely to come in contact with matters in a state of solution. The tongue of fishes can rarely be an organ of taste, being of a hard consistence, and frequently armed with teeth; their voracity and the element in which they live are also against their possessing in the tongue anything more than an organ of touch. In all the vertebrates the tongue answers for other purposes than that of taste; in the toad it is darted with great quickness and usually unerring aim against the insects upon which it feeds; in the chameleon it is capable of considerable protrusion, enlarged at the end, and covered with a glutinous secretion which entraps its insect prey when projected against them. In birds it is chiefly an organ of prehension, rarely possessing papillæ, and generally sheathed in front with horn; the tongue of the woodpecker is a kind of barbed spear, protruded by a muscle and long bony tendon from the top of the head, for the transfixion of grubs and insects. In mammals generally the tongue is only an organ of taste; but in the giraffe it forms a long flexible process, which can take up small bodies almost like a hand, and by which the leaves of high trees are stripped off into the mouth; the tongue of the ant-eater is covered with a viscid secretion, to which the ants adhere in great numbers; in the cats it is beset with strong spines for purposes of prehension and of tearing the small fibres of the flesh on which they feed; in man it is also of the first importance in the articulation of words.—The sense of smell doubtless exists in many invertebrates, at the entrance of the respiratory passages. In fishes the organ of smell consists of a sac containing a folded membrane largely supplied with nerves, and not communicating with the mouth or pharynx; that this sense is acute in the cod and other deep swimmers is probable from the fact, well known to fishermen, that these may be attracted from great distances by peculiar kinds of bait, while the top-water and mid-water species select their food by the sight, also often showing what seems to be a decided sense of taste; the sharks, from their large olfactory nervous centres, are believed to have an acute sense of smell. In the higher amphibia the nostrils become reptilian, being partly osseous and opening into the anterior part of the mouth; in saurians and chelonians the nostrils open posteriorly into the pharynx. In birds the external nostrils vary much in size, shape, and situation, but are generally freely open; their sense of smell is not so acute as had been supposed from some of the habits of the vultures, as Audubon has satisfactorily shown that these birds detect their carrion prey from great heights by the sense of sight and not by that of smell. In mammals the olfactory lobes are much more fully developed than in man, as also are the nasal cavities in which the sensitive membrane is spread out, and the external nose; the nostrils are valvular in the cetaceans, beavers, seals, &c.; in the hog the nose is enlarged into a gristly ring, in the tapir into a short proboscis, and in the elephant into a long prehensile trunk. The sense of smell is most acute in the carnivora and ruminants, as would be expected from the extent and convolutions of the turbinated bones. From the communication of the nose with the pharynx, mammals are able to breathe with the mouth shut.—An organ of hearing may be detected in many invertebrates, as in the lobster, insects, and cephalopods. Its simplest form in the vertebrates is in fishes, where it is a sac filled with fluid, in which are distributed the nervous filaments on small particles of calcareous matter; in connection with this sac are two or three semicircular canals opening

into its cavity; the auditory nerve arises from the side of the spinal bulb, without any distinct ganglion; in such an ear as this the vibrations of the water are communicated to the skin, then to the fluid, and finally to the nerves. Sonorous impressions are conveyed with greater intensity in liquids than in air, so that the sense of hearing in fishes may be tolerably acute. In the sharks the semicircular canals are quite large, and the vestibule of the *carcharias obscurus* would contain the whole internal human ear; of course in such an organ there is no tympanic cavity, and no external ear. In the aquatic amphibia the organ of hearing is like that of fishes; but in the frog and salamander there is a membrane of the tympanum. In the reptiles there is added a cochlea with its own nervous filaments, the tympanic cavity is larger, and a bone, the *columella*, makes a communication between the vibrating membrane and the fluid of the auditory sac; a Eustachian tube communicates also with the throat, and the tympanum is either bare on the level of the skin or just underneath it. In birds there is no external cartilaginous auricle, as in mammals, and only a portion of the external auditory canal; but in many, especially in the rapacious families, the feathers are erectile around the meatus, and arranged to catch distant sounds; the bone-surrounded tympanum has also its columella, and its cavity communicates with the fauces by a Eustachian tube, and with the air cells of the skull; the cochlea is more developed than in reptiles, but, like the rest of the internal ear, does not reach the perfection of the mammalian type. In the owl there is a crescentic valvular fold of integument around the external ear. In mammals there is a perfect cochlea, a chain of three tympanic bones, an external canal, and an external movable ear; in cetaceans and other aquatic families, the external ear is either wanting, very small, or provided with a valve; in ruminants and the timid rodents it is large and directed backward; in the carnivora it is small and inclined forward. The use of the external ear in man is not exactly determined; its small size and direction would make it of but little use in collecting sounds and transmitting them to the tympanum. The experiments of Savart go to show that it acts not only in reflecting sounds, but as a conductor, by virtue of the elasticity of its cartilage. In general the ear of mammals resembles that of man. In all animals living in air the vibrations of sonorous bodies are transmitted to a tense membrane, the *tympanum* or drum; the tympanic vibrations are transmitted to the fluid of the internal ear, in which the nerve floats, by the chain of bones; and in order that the membrane may vibrate freely, the cavity of the tympanum communicates with the throat, the tension being equal on both sides.—The most complicated of the organs of special sense is the eye. In all vertebrates the eyes are two in number, and with few exceptions symmetrically arranged on the sides of the head; they are essentially on the same general plan, the differences being chiefly in relation to the density of the medium in which the animals reside. Aquatic animals, whether fishes, reptiles, birds, or mammals, have the lens nearly spherical to compensate for the similarity of the densities of the humors of the eye and the surrounding water. In fishes the eyes are generally large and on the sides of the head, though they are small in the eel, directed upward in *uranoscopus*, and both on one side in the flounder; the cornea flattened, the sclerotic thick and sometimes partly ossified, the pupil large and round, the lids rudimentary, and the lachrymal gland wanting. The blind fish (*amblyopsis*) has been found to possess a sclerotic and choroid coat, a layer of cells beneath the latter resembling a retina, a rudimentary lens, and a nerve; still there is no trace of eye dots on the skin, though such were found in the mass of areolar tissue occupying the usual situation of the orbit; such an eye cannot be regarded as an organ of vision, as the skin and tissues beneath prevent the passage of light except in a very faint degree; but such as it is, it corresponds to the vertebrate, and not to the invertebrate eye, with the last of which it has been sometimes compared; the deficiency of vision in this species is made up by the largely developed organ of hearing, and by the remarkably sensitive papillæ on the head supplied by the fifth pair of nerves. In the aquatic amphibia the eyes are like those of fishes; in the higher genera, and in reptiles, except ophidians, there are lids moving vertically, a lachrymal apparatus, and a movable iris; in the snakes there are no lids, but the skin passes directly over the cornea, as in the eel. In birds the eyes are always well developed; from the anterior convexity and lateral location, their sphere of vision is very extensive; the retina is quite thick, and apparently gives origin to a fan-shaped dark membrane, the *pecten plicatum*, which extends from the entrance of the optic nerve toward the lens; from its being composed chiefly of vessels, some think it a process of the choroid, and accordingly its use may be either to absorb superabundant rays of light to extend the visual surface, or perhaps, as Owen has suggested, to push forward the lens by its erectile property. The pupil is round, the iris very contractile, the cornea large and transparent, and the sclerotic strengthened in front by a series of bony plates; there are two horizontal lids, the lower largest and most movable, and a third vertical nictitating membrane, semi-transparent, which may be drawn over the cornea from the internal angle; lachrymal glands are also present. There is some apparatus in the eyes of birds, either the pecten or the muscles, by which these organs can adapt themselves to the very different distances at which it is necessary for them to have distinct sight, by which the curvature of the lens and the focus of vision may be changed. In mammals which seek their food by night, the

eyes, like the ears, are proportionally larger than in the day feeders, and their pupil, when contracted, assumes the form of a vertical slit instead of a circular aperture; in the moles and subterranean species the eyes are extremely small, and sometimes quite rudimentary; in the aquatic genera the lens is more spherical, as in fishes, and in cetacea the lids are imperfectly developed and the whole organ comparatively small; in carnivora especially there is at the bottom of the eye a brilliant *tapetum*, which shines at night with metallic reflections; the lids are generally formed as in man, the upper being the largest and the most movable; except in man and monkeys, there is usually a third nictitating membrane. The direction of the eye in man and monkeys is forward; but as we descend in the scale it becomes lateral, so that the animal cannot see directly before him, and the sphere of vision becomes different for each eye.—*Organs of Alimentation and Digestion.* There is no organ so characteristic of the animal, as distinguished from the vegetable, as an internal digestive cavity for the conversion of organic substances into nutritive material. In the sac-like polyps the food is introduced into the simple stomach, and dissolved without any mechanical division; in the echinoderms there is a complicated apparatus of teeth, and the digestive cavity is arranged in a radiating manner; in the higher invertebrates and all the vertebrates there is a distinct mouth, an apparatus for mastication, a stomach for digestion, and an intestine from which the nutrient matters are absorbed and the useless materials are expelled. Accessory salivary, biliary, and pancreatic organs are found from the higher radiates up to man; in vertebrates the teeth are confined to the cavity of the mouth, and generally to the jaws, none being found in the stomach. Fish are very voracious, and most of them live upon animal food, swallowing whatever small prey they can obtain; a few have no teeth, but they are usually well provided with them, the sharks having several rows; the teeth are found not only in the jaws, but on the palate and vomer, the tongue, the branchial arches, and pharyngeal bones; they are numerous, without roots, united to the bone which supports them, deciduous and replaced by others growing under or by the side of the old ones, and thinly covered with enamel; the form is generally conical, as they serve only to retain or tear their food, rarely to crush and grind it; they are numerous and sharp in the pike and salmon, serrated in some sharks, flat and pavement-like in the rays, strong fangs in the wolf-fish, in others soft and velvety, tuberculated, or sharp-edged, and absent in the sturgeon and the sucking genera: to fit them better for their prehensile office, they are placed alternately, and not opposed to each other as in masticating animals. The salivary glands are absent, or very rudimentary; the gullet is short and wide, with its membrane folded longitudinally; the stomach varies in shape from globular to long and tapering, with both orifices near together and guarded by constrictor muscles; the intestine is short as in all carnivorous feeders, and not divided distinctly into large and small; to compensate for its shortness, the intestine in the sharks is provided with folds arranged in a spiral or longitudinal direction, which delay the passage of the food and greatly increase the absorbing surface; the anus varies in position from under the throat to the base of the tail. The liver is soft, light-colored, of large size, and many-lobed, discharging its bile into the commencement of the intestine, while the pancreas pours in its secretion on the other side; the latter organ is a large gland in the shark, but it is more commonly a series of tubes or cæcal appendages, the simplest form of a gland, placed around the pylorus; digestion is rapidly performed, and the chyle is taken up by numerous lacteals which end in the venous system near the heart. The spleen is small, of various forms, attached to the stomach, generally simple, but lobulated in the sharks. The amphibia resemble fishes in their digestive apparatus, in their prehensile teeth in the palate and jaws, in the absence or rudimentary condition of the salivary glands, in the short and wide gullet, narrow stomach, and short and simple intestine; in some of the higher forms they approach the reptiles, in the less numerous teeth, elongated tongue, and distinct small and large intestine. In snakes and saurians, mostly carnivorous, the intestinal canal is shorter than in the herbivorous testudinata. In serpents, which feed on living prey, the sharp conical teeth are directed backward, and the bones to which they are attached are freely movable, enabling them to swallow animals considerably larger than themselves; the venomous genera have in front of the teeth of the upper jaw two long curved fangs, communicating by a canal or a groove with the poison gland behind and below the orbit; the muscles which close the jaws press the venom into the wound made by the teeth; in the rattlesnake these fangs are movable, and may be bent backward in a fold of the gum when not in use; behind the ones actually employed, there are the rudiments of others which soon complete the terrible armature if one fang happens to get broken. The tongue is long, sheathed, and bifurcated; salivary glands are present; the gullet is long and very extensible; the stomach capacious, simple, and capable of great distention, separated from the intestine by a distinct valve; the duodenum receives the biliary and pancreatic secretions, and begins to present a villous surface; the large intestine is distinguishable from the small by its size, and ends in the cloaca with the ureters and genital openings; the liver, spleen, and pancreas are elongated to conform to the shape of the body. In the carnivorous saurians the arrangement is equally simple, though the teeth are fewer, chiefly in the jaws, the stomach short and rounder; in the iguana and other vegetable

feeders, the intestine is the longest. In testudinata, instead of teeth the jaws are armed with sharp edges of horn; the tongue and gullet are provided with long papillæ, sharp in the marine species; the salivary glands are tolerably developed; the gullet is long, wide, and muscular, and the stomach wide and fleshy; the intestine is about six times the length of the body, and the colon has a short, wide cæcum; the canal opens into a general cloaca. The food of birds is so various that their digestive apparatus would be expected to present considerable differences, and in no part is there greater variety than in the bill, which in most species is the principal organ of prehension, whether the food be seeds, insects, fish, or the flesh of animals. The bill furnishes to the zoölogist as good characters for the classification of birds as do the teeth for that of mammals; its exterior and the sharp edges are covered with solid horn, but it never has any true teeth, so that there is no proper mastication in this class; the birds of prey have the upper mandible short, strong, curved, and terminating in a sharp point, and in the falcons with a tooth-like process on each side, indicating by these characters the more or less carnivorous propensities of the genus; the tooth-billed hawks are the boldest, while the vultures, with their more elongated beaks, rarely attack living animals; in the parrots and granivorous birds it is broad and powerful to break hard shells and seeds; in aquatic genera it is broad for obtaining worms and insects from water and mud; in insect-eaters it is long and slender, or short and broad, according as the prey is taken on the wing or not, as in the bee-eater in the first case, and the whippoorwill in the second; it is long and straight in the king-fisher and heron for seizing small fish or reptiles; in the pelican the under mandible is provided with a large pouch for holding fish, and in the hornbill the upper is surmounted by a large and hollow casque. As the food does not undergo mastication in the mouth, the salivary glands are small; the gullet is wide and muscular, and capable of great distention in birds of prey; at the lower part of the neck it communicates with a membranous pouch, called the crop, in which the food undergoes a softening preparatory to stomachal digestion; the crop is largest in the granivorous birds, but it is found in the rapacious orders, though absent in the ostrich and the fish-eaters. Below this the gullet becomes smaller, but shortly dilates again into a second digestive cavity, or *proventriculus*, whose internal surface is studded with numerous follicles, generally of small size, sometimes hardly perceptible, but large in birds which have no crop; it secretes a fluid analogous to the gastric juice. This second stomach opens into a third, the gizzard, where chymification is completed, of variable size and structure; in carnivorous birds the gizzard is thin and membranous, while in the granivorous it is thick and muscular for compressing and crushing their hard food, performing the office of teeth; the lining membrane assumes a hard cartilaginous character, just as the skin of the palm and heel of man does; when circumstances favor or require it, mucous membrane may thus change into skin, as far as its dense cuticular layer is concerned; the power of the gizzard in the ostrich is enormous, wearing down the hardest substances; in gallinaceous birds its grinding action is assisted by the swallowing of pebbles, which serve the purpose of the gastric teeth of crustaceans and other invertebrates; the food of a bird may be known by the simple inspection of its gizzard, so close is the relation between its muscular power and the substances to be reduced by it. The intestine is much shorter than in most mammals, and consists of small and large, the latter having two tubular appendages, or *cæca*, at its junction with the former; these cæca are very small in the birds of prey, and largest in the gallinaceous order; the rectum is dilated near the anus, forming a *cloaca*, in which the ureters, oviducts, and male genitals end. The liver is large, filling a considerable part of the thorax and abdomen, usually two-lobed, with a gall bladder and hepatic ducts; the pancreas is long and narrow, lodged in the first convolution of the small intestine; the spleen is small, variously shaped, and situated beneath the liver.—The teeth are most perfectly developed in mammals, in which they serve not only for mastication, but for defence, attack, and locomotion. The structure of teeth presents three different substances: a central portion, forming the principal part of the bulk, characterized by minute canals radiating from the pulp cavity, the ivory or dentine; the enamel, investing the exterior and crown with a thin layer of extreme hardness; and the cementum, or *crusta petrosa*, covering the roots and sometimes around the crown with a thin lamina like bone. These three substances are well seen in the grinder of an elephant, in which the central part is made up of ivory, in a series of ridges covered with enamel, and this last, except on the surface, concealed by crusta petrosa; the hard enamel leaves a projecting grinding surface, while the other two substances are worn away. The teeth in vertebrates are shed at least once, and in some many times; those of fishes and reptiles are continually undergoing this process; in most fishes and snakes the teeth shed have between them others which remain attached to the jaw or the soft parts, until new ones are formed, to be shed in their turn; in some fishes, the crocodile, and most mammals, the new teeth are developed below the old, which they push out, after the roots are absorbed and the crown drops off; in the elephant and mastodon the new teeth are formed behind the old ones, gradually sliding forward as the latter are worn away. In man and in most mammals there are three kinds of teeth: the incisors, in front, with thin and cutting edges; the canines, conical, next to the incisors, four in number, in all animals except man longer than the other teeth,

destined to tear and to cut; and the molars or grinders, with a wide and irregular surface, for crushing and bruising the food. These different kinds of teeth are arranged in mammals according to the nature of their intended nourishment; and a simple inspection of the dentition indicates the kind of food, the habits, and even the structure of most animals. In the carnivora, or flesh-eaters, the canines are long, and the molars are compressed and sharp-edged, shutting like the blades of scissors; in the insect-eaters the molars are beset with conical points, meeting accurately in each other's interstices; in the fruit-eaters the surface of the molars is provided with rounded tubercles; in those which feed on hard grains, the grinding surface is flat and rough like a millstone; in the gnawing animals the incisors are greatly developed, and the enamel is so arranged that the wearing of the tooth keeps its edge sharp and chisel-shaped. Of these different forms of teeth the molars are the most constant and important, bearing the strictest relation to the habits of the animal. Between the carnivora and the herbivora, the flesh-eaters and the vegetable-feeders, stands man: he has all the kinds of teeth equally developed, of the same length, and in an uninterrupted series, and of course his natural food is a mixture of animal and vegetable substances; placed in unnatural circumstances and in extremes of heat and cold, the animal or the vegetable element must predominate for the preservation of health, according to latitude. Teeth are sometimes used wholly as weapons of attack or defence, as the long incisors or tusks of the mastodon and elephant; or as the single incisor of the narwhal, developed in the male, generally on the left side, into a long spirally twisted horn, that of the right side being rudimentary and concealed in the jaw, and both being rudimentary in the female. The tusks of the walrus serve also in locomotion, for pulling its unwieldy body up steep banks or blocks of ice. The teeth are wanting in the ant-eaters and pangolins; in the Greenland whale they are replaced by large, flexible, horny plates, called whalebone, in the upper jaw, the lower one having neither teeth nor plates; the upper incisors are wanting in ruminants, the lower in the walrus; the canines are absent in rodents, some ruminants, and most female solipeds; in the ornithorhynchus of New Holland the muzzle is prolonged into a wide, horny beak, flattened like that of a duck, and like it furnished with transverse lamellæ on the edges. The salivary glands are largest in herbivora. The gullet is wide and dilatable in carnivora, narrow in herbivora, and its fibres are arranged generally very much as in man.—The shape of the stomach varies much according to the food; it is usually simple, but multiple in the ruminants. The animal food of the carnivora requires a simple stomach and a short alimentary canal; in the quadrumana and less carnivorous families, where the food is more mixed, the organ becomes larger transversely; in the lion the intestine is not more than three times the length of the body, and in some others of the family it is difficult to distinguish the large from the small. In the ruminants the stomach consists of four distinct cavities: the first, or paunch, receives the crude, unmasticated food while the animal is grazing; this occupies a large part of the abdomen, especially on the left side; the second, or honeycomb, is small, on the right of the gullet and in front of the paunch, of which it seems a mere appendage; its mucous membrane presents the polygonal cellular structure noticed in tripe; the third, from its numerous folds, is called the manyplies; and the fourth, at the right of the last, the *abomasum* or rennet bag; this secretes the gastric juice, and is the proper digestive cavity. The first three stomachs communicate directly with the gullet, which opens almost equally into the first and second, and by a narrower canal into the third. It may appear strange that while the coarse food enters the first cavity, after it has been brought back to the mouth and masticated it should enter the third; the experiments of Flourens show that this is the necessary result of the anatomical disposition of the parts, as follows: the unchewed food, when it arrives at the part of the gullet which is continued in the form of a tube, mechanically separates its borders and falls into the paunch; but when drinks or fine semi-fluid substances present themselves, the canal is not dilated, and they naturally pass chiefly into the third cavity; it is consequently the occlusion or dilatation of this canal which determines the entrance of the food into the first or third stomach, and it is the volume of the substances swallowed which opens or not this canal. The act of regurgitation from the paunch to the mouth is supposed by some to commence in the second cavity, which seizes a portion of the alimentary mass, compresses it into a rounded form, and forces it into the gullet, by whose vermicular contractions it reaches the mouth; others believe, with Flourens, that the two stomachs force the mass into the œsophageal canal, which detaches a portion and forces it upward. Of these cavities the first is by far the largest, and the third the smallest; in early life the fourth is the only one developed for the reception of milk. In the camel and dromedary the paunch is fitted to receive large amounts of water in one of its compartments, the first answering to a paunch, and the second, the water cavity, to the honeycomb. As a general rule we find the stomach most complicated in herbivora, and the simplest in carnivora; yet there are many exceptions to this; for instance, in the horse, whose food differs but little from that of the ox, the stomach is simple; in some carnivorous cetaceans it is very complicated. The intestines are generally long, large, and sacculated in proportion to the vegetable nature of the food, but to this also

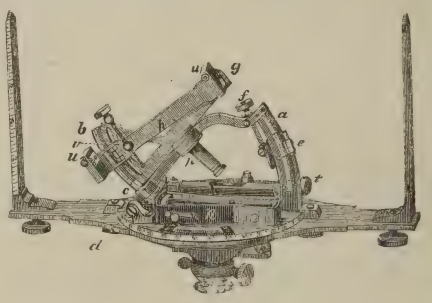
there are remarkable exceptions; in frugivorous mice they are only three times the length of the body, while in the carnivorous seal they are twenty-eight times, the anomaly being probably explicable by the greater development of the cæcum in the former. In the elephant the total length is about 60 feet, in the camel 130, in man from 25 to 30; the intestine is 10 times the length of the body in the horse, and 28 times in the sheep; in an ornithorhynchus 17½ inches long, the intestinal canal was 5⅔ feet, ending in a cloaca as in birds. The liver is large in cetacea, smaller in herbivora, and least in carnivora. There seems to be no general law for the presence or absence of the gall bladder; it is said that all the mammalia in which it is absent, except the porpoise, are vegetable-feeders. The spleen, pancreas, peritoneum, and other appendages of the digestive cavity, are much like those of man, from which they differ principally in shape; the biliary and pancreatic fluids are received into the duodenum. Absorption is effected in the lowest animals by simple membranous surfaces, without the aid of vessels or tubes; the latter are gradually added, and in man and the higher animals like cylindrical processes in immense numbers are developed in the intestinal mucous membrane, the *villi*, by which the nutrient materials are absorbed and conveyed into the circulation. In all vertebrates there are special vessels, the lacteals, in the coats of the intestine, for the absorption of chyle, which convey it to the thoracic duct, from which it is poured into the venous blood near the heart; in fishes they are destitute of complete valves, which exist in reptiles, and in both these classes their convoluted arrangement supplies the place of glands; the fluid contained is limpid in the fish and milky in the reptile; in birds, glands appear in connection with the lymphatics, but not with the lacteals, and the valves are more numerous and distinct; in mammals the chyle assumes more of the characters of blood, the valves are increased in number, the glands are numerous in the mesentery, and the thoracic duct becomes a distinct vessel, occasionally double.—*External Covering.* The skin of fishes is generally covered with scales, varying from rough grains to large flattened tubercles or thick plates, and thin lamellæ overlapping each other like the tiles on a roof; they are held by folds of the skin, very much like the nails, which they resemble except in being more calcareous. Carpenter considers the scales of fishes as developed in the dermis, and those of reptiles as mere epidermic appendages, like nails, hoofs, feathers, and hairs. They are ornamented with the most beautiful and varied colors, presenting all the metallic reflections. The most recent chemical researches have established that fish scales have the constitution and many of the peculiarities of structure and growth of bone; the arrangement of the lacunæ and their forms are of importance in studying the resemblances of allied fishes; they are composed chiefly of phosphate of lime, and contain a little magnesia and fluorine. The order of development of the scales in osseous fishes is not well ascertained; but in young garpikes (*lepidosteus*), according to Agassiz, a row of scales is first formed along the middle line of the body; as the age advances, other rows appear above and below the median line, and the scales are crowded together and of a rhomboidal form toward the tail; the same is true of the sturgeon and other ganoid fishes. From the study of fossil species, Agassiz was led to recognize and to classify fishes by the structure of the scales; he found that all living species resembling the ancient types had scales of a peculiar structure. A common scale is composed of successive layers of horny or bony matter, the oldest layer being the lowest; over this bony layer in fossil fishes is a covering of enamel-like substance as hard as that of the teeth; by this character the affinities of many modern species have been determined. The sharks and rays have scales which consist only of enamel, forming rough points, known in the former as shagreen; these he called placoids. Finding singular coincidences between the structure of scales and the general form and internal organization, he united the sharks and rays into one order, characterized by a cartilaginous skeleton, by a separation of the vertebral column from any upper or lower appendages, by teeth without sockets, attached to the jaw by skin and movable, and by the gills being covered only by strips of skin, forming as many openings on the sides or under part of the head as there are gills. The fishes whose scales are covered by enamel he called ganoids, embracing among living species the sturgeon and the garpike of North America, and among fossils some of the most remarkable forms, well described in the works of Hugh Miller; the scales in this order are extremely hard, and more or less smooth, and with the reptilian character of vertebræ united by ball-and-socket joint. These two orders were numerous at the remote geological epoch before reptiles, and consisted of many genera, with species of great size; the types of these ancient fishes are now reduced to a very few genera. These first created vertebrates he considers, in his "Essay on Classification," as classes of the animal kingdom distinct from fishes proper. In ordinary bony fishes he found two types of scales: in one they consisted of simple layers with regular outlines, and in the other the edges were serrated posteriorly, the serrations becoming more numerous and the surface more rough as the scales increased in size; the former he called cycloids, the latter ctenoids. Ctenoids have bony spines in the anterior portion of the dorsal fin, and serrations or spines in the opercular bones; this order includes the perch family, and others with spiny dorsals and rough scales; the flat fishes (*pleuronectes*), characterized by their

want of symmetry on the two sides, are an exception in having rough scales with soft fin rays. Cycloids, embracing fishes with smooth scales, like the cod, herring, trout, and eel, are the most numerous types in the present epoch; the rays are soft, and the bones of the head are smooth and simple; the mackerel has hard rays, and both serrated and smooth scales, and seems intermediate between cycloids and ctenoids. It appears, therefore, that this division into four orders according to scales is not perfect, and it is not now much insisted upon by its author, except for the first three. So intimate is the relation between the scales of fishes and their general organization, that Agassiz was enabled to restore a fossil fish from isolated scales, as is shown in his work on "Fossil Fishes;" in like manner Cuvier repeatedly restored fossil genera of mammals, giving the entire skeleton and outline of the form, from single bones found in the gypsum near Paris. In testudinata, the corneous integument is applied directly to the bony box which encloses their soft parts; the epidermis is covered with large scales, adherent by all their lower surface, except in the species which produces the tortoise shell of commerce, in which they overlap each other; these plates grow by all their adherent surface and at their circumference, as indicated by the concentric lines of increase, and become larger in proportion to the body; on the neck, tail, and limbs the epidermis is like that of mammals, except in being thicker and rougher. The scales of other reptiles are implanted on the dermis, and vary from horny in most genera to bony in the crocodile; contiguous by the borders on the head, and generally imbricated on other parts of the body; of various shapes and sizes, and arranged in serpents in long bands, moved by muscles, serving the purpose of limbs by their contact with the ground at their free posterior edges; the epidermis covers even the scales, and at certain seasons of the year is shed; in serpents the change is so complete that the cast skin comes off in a single piece, including even the covering of the eyes; the coloring matter, often of the most brilliant hues, is placed immediately under the epidermis. In batrachians, the skin has no corneous appendage, except the nail-like processes of the limbs in a few species.—The feathers of birds are analogous to the hairs of mammals, but more complicated in structure; they are believed to be not the simple product of a secretion, as is frequently maintained, but developed from bulbs formed from cells and supplied with vessels; when the feather is formed the vessels disappear, and it gradually becomes dry and dead from the summit to the base, and finally is not susceptible of further living changes, resembling in this respect the horns of the stag. Each principal feather may be moved by means of the greatly developed cutaneous muscles, which send slips to them. A feather usually presents at its lower extremity a corneous tube open at the end, continuous with the shaft, which is webbed on each side, with fringed barbules. According to F. Cuvier, the capsule which forms the feather grows during the whole development of the latter; the bulb, after it has fulfilled its office, forms in drying a series of membranous cones in the tube, generally called the pith. The new feather is at first covered by the investing capsule, which often extends several inches from the skin; it gradually becomes free, and the barbs, at first rolled up, spread laterally; the end of the tube is implanted lightly in the skin, and at every moulting season is displaced for a new feather; moulting takes place generally every year after the season of incubation, and sometimes twice a year, and is a period during which the bird loses its voice, and appears more or less unwell. Some feathers resemble the quills of the porcupine, as four or five of those in the wing of the cassowary; in the eagle the barbs are stiff and united by hooked barbules into a broad lamina for retaining better hold on the air; in the ostrich the plumes of the tail and wings are of great softness and lightness, and in the marabout the feathers resemble the softest down; in the turkey's breast they are transformed into bristly hairs, and in some cuckoos into corneous plates at the ends. It is unnecessary to more than allude to the magnificent and varied colors of these appendages, which are usually the finest in the males and in adults.—In a few mammals the skin is naked, but in the greatest number it is protected by hairs, characteristic of this class. Hairs are produced, like feathers, from cutaneous follicles or capsules lined with a cell membrane, and containing at the bottom a conical bulb supplied with blood, the soft interior constituting the pulp. Various as are the forms of hairs, they consist essentially of an external corneous cortical substance, and a medullary matter in the interior; the quills of the porcupine are only magnified and modified hairs, their cortical substance being very dense, and the medullary matter a pithy aggregation of very large cells, without any evident fluid portion in the perfect quill; so in birds, the cortical substance is found alone in the quill, while the cellular pith is confined to the shaft; in some animals the cortical substance is strongly imbricated, and the medulla made up of rounded cells. Pigmentary matter is developed in the central portion. Hair is, therefore, the product of epidermic cells, developed in abundance in the follicles, and it grows by the addition of new matter at the base. Hairs may become spines, bristles, wool, or down, according to softness and fineness; their color varies much, though less than that of feathers, being generally some modification of white, black, reddish brown, or yellowish. Recent observations seem to connect the supra-renal capsules with the regulation of the amount of pigmentary matter in man and animals. Hairs, like feathers, are usually shed once a year, with or

without change of color and character; in winter the fur is finer and thicker than in summer, being intermixed with more downy fibres. Hairs sometimes are so closely approximated as to form horns or solid plates; the horn on the nose of the rhinoceros is made up of firmly united hairs; the shields of the pangolins seem to be the product of hairs intimately consolidated, and the latter are seen projecting from the former in various parts of the body. The whiskers on the nose of carnivorous and rodent animals have the bulb projecting far into them, and are freely supplied with vessels and nerves, forming very sensitive organs of touch.—In this imperfect sketch of comparative anatomy, it must be evident to the most superficial observer that there is a general plan of structure in the animal kingdom, varying in its details, but always pointing to man as the head of creation, as the most perfect of the inhabitants of the earth. The contemplation of this vast picture of animal life is most exalting and ennobling to the devout student of nature; following the endless varieties and marvellous adaptations of created types, the mind at last must rest on the infinite wisdom and power and goodness of the supreme Architect of the universe. Those who wish to pursue this vast subject in its details are referred to the writings of Cuvier, John Hunter, Home, Carus, Müller, Meckel, Bell, Oken, Owen, Grant, De Blainville, Saint-Hilaire, Carpenter, Siebold and Stannius, Flourens, Strauss-Durckheim, and the various articles in Todd's "Cyclopædia of Anatomy and Physiology."—HISTORY OF COMPARATIVE ANATOMY. Though the philosophers of Greece had some idea of the internal structure of the animals offered as sacrifices to their gods, it was not until the time of Aristotle, or the 4th century before the Christian era, that we find any scientific treatise on comparative anatomy; the first chapter of his "History of Animals," though very imperfect, and even erroneous, in anatomical details, may be regarded as the first work written on this science. He was an exact observer, a patient collector of facts, and studied successfully many laws of nature not before recognized. After him came Theophrastus and Erasistratus. Galen, in the last half of the 2d century A. D., made many dissections of animals, of the anthropoid monkeys, and it is believed of man himself. During the middle ages the science of comparative anatomy fell into oblivion, from which it did not emerge until the 14th century; in the 16th and 17th appeared the writings of Berengario, Vesalius, Rondelet, Aldrovandus, Riolan, Harvey, and C. V. Schneider. Up to this time the science had only been studied in its separate details; the Neapolitan M. Aurelio Severino, in his *Zootomia Democritea*, first united the scattered fragments in a general treatise on comparative anatomy in 1645; after him Collins, in England, pursued the subject into the domain of natural history and pathology. The more minute organisms of the invertebrates began now to attract attention, and were well studied by Ruysch, Steno, Willis, Malpighi, Swammerdam, and Réaumur. In France, the academy of sciences early occupied itself with this science. In the latter half of the 17th century Perrault, Duverney, and Méry made exact observations on the structure of reptiles and fishes. About this time Needham in England, Redi in Italy, and Leeuwenhoeck in Holland, were pursuing their researches with the microscope on the minute animals, which Raspail and Ehrenberg have since so successfully illustrated. Up to this period a great multitude of scattered facts were brought together by the industrious compilers Blaes and Valentini, and in Manget's *Bibliotheca Anatomica*. With Boerhaave, in the early part of the 18th century, the science received a check from which it did not recover for nearly 50 years. He was a skilful botanist, but a poor zoölogist, and dogmatically maintained that the study of comparative anatomy could in no way advance the knowledge of the functions of the human organism. Notwithstanding this high authority, the great Haller, Spallanzani, and Ch. Bonnet continued their valuable observations on the general and comparative structure of man and animals. Physicians now had begun to consider this science as quite foreign to the art of medicine, but naturalists had already conceived the happy idea of making it the basis of a natural classification in zoölogy. Buffon was the first to perceive the full importance of the relation of comparative anatomy to natural history, and Daubenton made it the basis of a zoölogical classification. If Linnæus and his followers had been more familiar with it, they would have made less erroneous divisions of the animal kingdom, especially in the class of worms. Encouraged by Daubenton, Vicq d'Azyr, famous for his discoveries in myology, in the anatomy of birds, his researches on incubation, and his description of the brain, conceived a vast plan for the illustration of comparative anatomy, which was frustrated by his early death, but was nearly realized in the beginning of the present century by the great Cuvier in his *Leçons d'anatomie comparée*. In the last 100 years, among the noted cultivators of this science were Barthez in France; J. Hunter and Everard Home in England; Pallas, O. F. Müller, Merrem, Schneider, Kielmeyer, and Blumenbach in Germany; Camper in Holland; Scarpa and Poli in Italy. The time of Cuvier marks the opening of a new epoch in comparative anatomy; he applied this science to natural history, physiology, and to the study of fossils. During this epoch have flourished Geoffroy Saint-Hilaire, Meckel, Oken, Carus, Panizza, Grant, and Owen, besides a host of writers of monographs on the various classes of the animal kingdom, and on special systems and organs. The first edition of the *Leçons* appeared about the beginning of the present century, and the second was the last work upon which Cuvier labored; for more than 30

years he had collected an immense amount of facts and materials, which are partly embodied in this book; it is a monument of patient industry, a model in arrangement, and a mine of knowledge of which all observers since have availed themselves; many of its unavoidable deficiencies have been supplied by later writers, especially by Meckel; in it are laid down not only the analogies, but the differences in the structure of organized beings. His *Ossemens fossiles*, published in the first quarter of the century, is invaluable for its scientific and minute descriptions of the bones and teeth of extinct and living vertebrates. Contemporary with Cuvier was Geoffroy Saint-Hilaire, whose writings on comparative and philosophic anatomy gave great impetus to the study of natural history. At the head of the German school of philosophical anatomy stands Lorenz Oken, who extended to natural science the principles which Kant had applied to mental and moral science. In 1802 he divided the animal kingdom into five classes, according to the predominance of the special senses; in 1805 he maintained that all organic beings originate from and consist of cells; in 1806, while walking in the Hartz forest, he picked up the blanched skull of a roebuck, and, after contemplating the partially separated bones, exclaimed: "It is a vertebral column!" In the following year he delivered the famous discourse on the "Signification of the Bones of the Skull," renewing the idea of the cranial and vertebral homologies, which has since been modified, extended, and perfected by Richard Owen. Carus, in his "Treatise on Comparative Anatomy," of which the second edition was published in 1834, devotes about half to philosophical anatomy and the geometrical construction of the skeleton, carrying out the idea of Oken, Saint-Hilaire, and Spix, that the whole bony fabric is nothing but a vertebra repeated. According to Oken, the head is a repetition of the whole trunk, with all its systems. Cuvier ridiculed the idea of these transcendental homologies, and at his death the vertebral theory of the skull had apparently fallen into oblivion. In Owen's "Archetype and Homologies of the Vertebrate Skeleton," this theory is briefly stated as follows: "The head is not a virtual equivalent of the trunk, but is only a portion, *i. e.*, certain modified segments, of the whole body. The jaws are the 'hæmal arches' of the first two segments; they are not limbs of the head." The head is not a repetition of all the rest of the body; the skull is a region in itself, consisting of a series of segments or vertebræ essentially the same as those constituting the rest of the skeleton. The endoskeleton of the cranium, according to Owen, consists of the occipital, parietal, frontal, and nasal vertebræ; the ribs of the first are the shoulder blades, and the divergent appendages of the anterior extremities; the divergent appendages of the second are the branchiostegal rays, of the third the operculum, of the fourth the pterygoid and the zygoma. The different modifications of the type skeleton will be treated in the article Philosophical Anatomy. Owen revived and reworked the idea of Oken, and brought it to the now generally admitted segmental constitution of the vertebrate skeleton, as fully illustrated in the above mentioned work.

COMPASS, a magnetized needle, balanced upon its centre so as to swing freely, used to indicate the magnetic meridian, and, by means of a graduated circle connected with it, the azimuths or bearings of objects from this meridian. The Chinese appear to have been acquainted with the property of polarity in the loadstone, and in iron or steel magnetized by it, and to have been the first to apply this. Some affirm that they employed only the loadstone (magnetic iron ore), floating it upon a piece of cork; and that the magnetized needle is the invention of Flavio Gioja of Amalfi, who lived in the early part of the 14th century. Dr. Gilbert, in his *De Magnete*, &c. (London, 1600), states that



Mariner's Compass.

the compass was brought to Italy from China by Marco Polo about 1295. But there is evidence of its having been used in France about the year 1150, in Syria about the same period, and in Norway previous to 1266. Several forms of the compass are in use. The mariner's, made for service at sea, and especially for indicating the direction in which the ship's head points, consists of a needle attached to the under side of a circular card or disk, upon the top of which the cardinal points and their subdivisions are marked. A *fleur de lis* is on the N. pole of the needle, and the letter S. on the opposite pole. E. and W. are placed, the one to be toward the east, and the other toward the west, when the card, swinging with the needle, comes to rest, dividing the circle into quadrants. A diameter is drawn, bisecting each of these, fixing the N. E., S. W., N. W., and S. E. points upon the circumference; and the arcs thus obtained are again bisected by

new diameters, again doubling the number of points; and the process is repeated upon the smaller arcs, obtaining in this way 32 points or divisions of the circle, each representing an arc of 11° 15′. The points are designated as follows for one quadrant, and on the same plan for the rest: N, Nb (by) E, NNE, NEbN, NE, NEbE, ENE, EbN, E. Lesser divisions sailors indicate by half and quarter points, thus: E. N. E. ½ E., N. E. ¼ N., E. ¾ N., &c. The degrees are also usually numbered around the margin of the circular card. An agate, or better a garnet cap, is set in the middle of the needle to receive the sharp pivot standing in the middle of the compass box, upon which the needle and card are balanced. This box is of copper or brass, of cylindrical or hemispherical shape, and covered with a glass plate to exclude currents of air and dust. It is supported in a ring by two pivots projecting from opposite sides of the box, and this ring is swung by two other pivots placed so that the line connecting them is at right angles to that connecting the other two. This contrivance, called "gimbals," is designed to keep the central pivot always vertical in the movements of the ship, the box being made heavy at the bottom, so that its centre of gravity is considerably below the points of suspension, in which it swings freely. The pivots of the outer ring are fixed to a frame or to the inside of a square wooden box, in which the instrument is placed. Instead of using gimbals, a cap with a pivot standing in the top of it is sometimes placed upon the stationary pivot, and the needle is balanced upon the top of the upper one. On board ship the compass is set in a receptacle called the binnacle, and the direction in which the vessel heads is indicated by a distinct vertical mark on the inside of the inner box, close to which the points upon the card pass as this swings round.—The compass used in land surveying is made with the graduated circle fixed to the plate of the instrument, the needle pointing the degrees at each of its extremities. Two sights are erected opposite each other on the plate which supports the box, on the line of 0°–180°, and the needle when at rest points to the degree representing the azimuth of this line. With an idea of facilitating the reading of the bearing of objects seen through the sights of the instrument, the letters E. and W. in land compasses are placed opposite the positions they occupy on the card of the mariner's compass. Reading always from the N. pole of the needle, and supposing the line of the sights to be directed toward S. 45° W., this N. end will be found half way between the letters S. and W. A very convenient form of the azimuth compass is a modification of that invented by Capt. Kater, and sometimes called the prismatic compass. The needle is suspended upon a pivot in a shallow cylindrical box, and supports by its extremities a silver ring graduated to 360°, with the half degrees and sometimes the quarters also marked by short lines. The N. pole of the needle is on the zero point, and the S. pole on 180°. A sight frame with a fine hair in an elongated vertical opening is attached by hinge or otherwise on one side of the box, and opposite this is a low sight piece, so arranged with a short slit in the top and an eyehole directly under it, in which is a small transparent prism, that the eye can at the same time observe the range of the sights upon any distant object, and read through the prism the number of the degree directly under it: thus if the bearing be N. 15° E., the number seen is 185. This instrument is of great service for rapid observations; it is carried in the pocket, is held in the hand when an observation is made, and may be read to 15′ by one accustomed to its use.—The force with which compass needles tend to range in the magnetic meridian was found by Coulomb and Kater to be influenced in those of the same form, not by the amount of surface, but by their mass, when fully charged with magnetism. Shear steel was found to be the best material, and the form of the needle an elongated lozenge, the middle portion cut out, and a bar of brass inserted across the centre to receive the cap. No advantage is gained in making them more than five inches long; on the contrary, several poles are apt to be produced, the effect of which is to lessen the force of the single polarity sought for.—The compass is liable to err in its indications from causes, some of a local and others of a general nature. The former are mostly beyond the skill of man to control; and, often acting when no suspicion of their existence is entertained, the compass cannot be regarded as an accurate instrument in running lines. It has, in fact, gradually been giving place to other methods of determining these. The effect of the declination of the needle, or its variation from the true meridian, is corrected by allowing for the amount of this variation as established for the place and time, or as determined by observations made for the purpose. On certain lines upon the earth's surface, called lines of no variation, the needle points toward the pole. Such a line at the present time passes near Wilmington, N. C., Charlotteville, Va., and Pittsburgh, Pa. On the eastern side of this line the variation of the needle is toward the west, increasing in amount with the distance from it. At New York the variation is 6° W. and at Portland, Me., it is 13° W. On the other side of the line of no variation, the declination is toward the east, being 5° E. at Key West, and reaching on the Pacific coast 15° or 20° E., or almost N., N. E. This variation undergoes a progressive change in amount, and, after long periods, changes in direction, vibrating, in fact, between certain limits. In the eastern states the north pole of the needle is moving westward at the rate of about 1° in 12 years. In London, in 1576, the variation was easterly 11° 15′; in 1657–'62 it was reduced to nothing, and then slowly advanced to its maximum in a westerly direction, which in 1815 was 24° 27′

18″. Since that time it has been slowly decreasing. It is thus perceived that surveys made by the compass should always be referred to the true meridian, or their date be given, that such reference may at any time afterward be made; but the latter method is not altogether trustworthy. The subject of these movements for this continent is treated in the reports of the proceedings of the American association for the advancement of science, at their ninth and tenth meetings.—The variation of the compass in ships from local causes is a matter of the most serious consequence, and baffles the skill of man to control its effects. It is not a constant determinable error, but varies with the position of the vessel; it is generally greatest when she heads E. or W., and least when she lies on the magnetic meridian. It is different also as the ship lies on even keel or careens over on one side. The liability of error increases with the increased use of iron in the construction of ships, and those built of it are found to act themselves as magnets, especially if they stood upon the stocks with the head toward the north. In this case, sailing for some time in a contrary direction tends to change their polarity and disturb the compasses. The plates are made magnetic by the blows they receive as the ship is constructed. The attention of scientific men has been directed for years past to the devising of some protection against this evil. In iron ships compasses are stationed in different parts, and comparative observations are constantly made of their indications. The most confidence is placed in those which are furthest from the hull, as at the mast head. In the British navy it has been the practice for many years to occasionally swing around each ship, and note the indications of the compass as she heads in different directions, and thus form a table of errors to be applied to correct the compass when she is afterward sailing on these courses. The board of trade recommended the adoption of this practice for merchant ships. Professor Airy, astronomer royal, objected to it, and recommends instead the use of magnets placed near the compass, and so arranged as to neutralize the influence of all other local attractions. He also advises frequent examination of the compasses, and testing them as often as practicable by azimuth observations of a star or other objects. In some ships a neutral point has been found in which the local attractions were all balanced, and so continued to be, rendering this a suitable spot for the compass. The discovery of a sure method of obtaining a neutral point of this character is an object of the highest consequence; but, however secured, there are so many causes to influence the condition of the needle, some slow and some sudden in their action, such as electrical currents induced by atmospheric agencies, the heavy shocks of the waves upon the ship, &c., that frequent observations and constant care are essential to make the compass a safe guide. Sir John Ross found that the needle was attracted full 5° by the rays of the moon concentrated upon it. The British admiralty have caused experiments to be made, and have invited competition, in the construction of the compass; and in consequence, from being a common, it has become an artistic instrument in that country, great improvements having been made in it.

COMPASS, Solar, an instrument invented by William A. Burt of Michigan, designed for determining at any place a true N. and S. line, from which other lines may be run in any desired direction. It is furnished with a latitude arc to be set at the degree of the latitude of the place, a declination arc to be adjusted to the degree of the sun's declination at the time, and an hour arc for setting off the hour of the

Solar Compass

day. The latitude arc, *a*, has its centre of motion in two pivots, one of which is shown at *d*. It is moved up or down within a hollow arc by the tangent screw *f*, and reads to single minutes by the vernier *e*. It has a range of about 35°, so as to be adjustable to the latitude of any place in the United States. The declination arc is represented at *b*, which as well as the latitude arc is graduated to quarter degrees, and reads to single minutes by the vernier *r*, which is upon the arm *h* with its centre of motion at *g*, the centre of the arc. It is controlled by the tangent screw, seen near the arc. The hour arc, *c*, is supported by the two pivots of the latitude arc, and moves in a plane perpendicular to the declination arc. Through the centre of the hour arc passes a hollow socket *p*, in which the spindle of the declination arc turns. The hour arc is read by the lower edge of the graduated side of the declination arc. The combination of the declination arc (which is for the purpose of adjusting the sights, *u*, *u*, to the declination of the sun, so that its rays may be made to pass through them) and of the hour arc constitutes a very accurate form of equatorial sun dial, the arm *h* being made to turn upon an axis parallel with the axis of the earth, and to show the hour by indicating the number of degrees measuring the angle which the sun's rays make with the plane of the meridian. The in-

strument also has a needle box, *n*, with an arc of about 36°. When the instrument is turned so that the rays of the sun penetrate a lens and form a bright focus between cross lines drawn upon a silver disk, the sights must be upon a true N. and S. line. A faint glimmer of the sun is sufficient, so that its use is not interrupted in the woods, nor in moderately cloudy weather. By reference to the magnetic needle attached to the instrument, the local variation is determined whenever an observation is taken. In hands accustomed to its use, it is adjusted in less time than is required for the needle of a surveyor's compass to settle. The perplexities caused by local attraction are avoided, and for this reason, and others also, it is much preferred to other instruments in running important lines upon the government surveys in the western states. The boundary line between Michigan and Wisconsin was run by it; and when used to determine the latitude at points on this line, the results agreed with those obtained by the very accurate surveys of Capt. Bayfield of the royal army. Capt. Talcott, in a letter to Mr. Burt, says that in running the line between Iowa and Minnesota, he could not distinguish upon the map of the largest scale the line it fixed from that determined by the most careful astronomical observations.

COMPIÈGNE (under the early Frankish kings, *Compendium*), a town of France, in the department of Oise, on the left bank of the river Oise, near the mouth of the Aisne, and on the great northern railway, 43 m. N. N. E. of Paris; pop. in 1866, 12,150. It contains a celebrated palace, originally built by Louis IX., rebuilt by Louis XIV., and improved by Louis XV. and Louis XVI., and by Napoleon I. From very early times Compiègne was a favorite residence of the kings of France; several parliaments were held there, and Joan of Arc was taken prisoner before its walls, the spot of her capture, marked by the ruined *tour de la Pucelle*, being still pointed out. In 1624 a treaty between Holland and France was signed at Compiègne. Charles IV., ex-king of Spain, resided some time in its palace, and Napoleon's first meeting with Maria Louisa took place

Palace at Compiègne.

here. Napoleon III. and his court frequently visited the place; the shooting parties given by him in the large adjoining forest, which abounds in game, enjoyed a high reputation in the fashionable world. The grounds were thrown open to the public in 1871. The town contains three splendid churches, a picturesque town hall, a fine bridge (*pont neuf*) over the Oise, a theatre, various other public buildings, and a public library.

COMPITALIA, or **Ludi Compitalitii,** a festival among the ancient Romans, instituted in honor of the *lares compitales*, or the deities who presided over the places where two or more roads met. The festival was of very ancient origin, and is said to have been restored after it had fallen into disuse by Tarquin the Proud, who caused boys to be sacrificed at it; but this was soon discontinued, and garlic and poppy heads were substituted for human sacrifices.

COMPLEXION (Lat. *complexio*), the color of the skin. This color exists in the epidermis alone, and depends upon the admixture of pigment cells with the ordinary epidermic cells. The ancient anatomists divided the skin into two parts or layers, the inner being denominated the cutis or dermis, and the outer the cuticle or epidermis. Malpighi was the first to discover what was thought to be a third layer interposed between the cutis and the cuticle, to which the name of *rete mucosum* was applied, from the circumstance that it was supposed to furnish mucus to lubricate those papillæ with which it was placed in immediate contact; it has also been called *stratum Malpighii*. Flourens went beyond Malpighi, and divided this middle portion of the skin into four layers: 1, one lying immediately on the cutis, of a cellular structure; 2, a continuous membrane presenting the characteristics of mucous membranes generally, on the external surface of which is spread a black pigment which constitutes the third layer; and 4, the inner portion of the epidermis, lying contiguous to the coloring matter. He displayed by maceration all these layers in the skin of a negro; but on subjecting that of a white man to the same process, he was unable to discover the pigment or the mucous membrane deposited upon it. He therefore concluded that the skin of the colored races has an apparatus entirely wanting in the white, and regarded this diversity

as forming a specific distinction, marking the European and negro as belonging to separate species; an opinion which, if the fact were true, would not admit of question, for, as Prichard remarks, the endowment of an entirely peculiar organ to one race of which no traces are to be found in the proximate tribe, is a much greater difference than is often to be found on comparing species which stand next to each other in the zoölogical series. There are many facts, however, which do not admit of explanation upon Flourens's theory. Among these are the discolorations which take place in the skin of European races, in certain disordered states of the constitution. During pregnancy many females have a dark tinge around the nipples, varying in intensity in different cases, and in some the entire abdomen is covered with a hue as dark as that of the negro. Bomare mentions a French peasant woman whose abdomen became completely black during each pregnancy. Camper gives an account of a female of rank who had naturally a white skin and beautiful complexion, which whenever she became pregnant began to grow brown. "Toward the end of pregnancy," he says, "she became in color a veritable negress." After delivery the dark color gradually disappeared. Dr. Starck mentions a man who after an attack of intermittent fever became as black as a negro. Blumenbach possessed a part of the skin taken from the abdomen of a beggar, which was as black as that of an African. Elliotson relates the case of a girl in St. Thomas's hospital, whose family were all white, but whose left shoulder, arm, and hand were of negro blackness, except that a stripe of white ran between the elbow and armpit; also that of a white woman who in 20 years became as black as a negress without any evident reason. A case is related in the *Journal Général*, where a woman became suddenly black from mental distress, and remained so. The blackness in this case was not caused by jaundice or congestion of blood, but by a change in the coloring matter of the rete mucosum. The "Transactions of the Medical Society of the State of New York" for 1858 contain a case of a change of color in the person of a female aged 16 years, reported by Dr. W. H. Gardiner. When the patient was first seen by Dr. Gardiner, Sept. 15, 1857, the discoloration of the skin had existed for about two years, and she presented in color the appearance of a dark mulatto with distinctly marked European features. Her father was of English, and her mother of American birth; both had light complexions, with light eyes and brown hair. All their children resembled them in complexion except the patient of Dr. Gardiner, who possessed the same complexion as her brothers and sisters until she had attained her 14th year. Soon after puberty some dark brown spots were observed upon her forehead, which looked at a little distance as if covered with fine dust. These spots were not constant, nor did they attract much attention until they had been present about two years. At the age of 16, after an attack of slight illness, her complexion grew rapidly darker, and in about two months had acquired the deep hue which it afterward bore. At this period she presented, when at a short distance, the appearance of a white person whose skin had been covered with a thin coating of lampblack, through which some appearance of the hue of the surface was apparent, with here and there spots, from a few lines to a fourth of an inch in diameter, which were as black as the skin of the darkest African. On removing the cuticle from one of these spots, it was found to be overspread with a pigment which had much the color of lampblack mixed with mucilage. The hair had changed from its original brown to black, and become coarse and straight. Her eyes were of light hazel, the whites presenting that pearly appearance peculiar to the colored races. Every portion of the surface was free from an icteritous tint. She died in the early part of October, 1857, from disease apparently in no way connected with the discoloration of the skin. These facts show that a physical change may take place by means of which the skin of an individual of a white race may become as black as that of the native of Africa. The coloring matter is likewise liable to be absorbed in the skin of those to whom it is natural, and instances are not uncommon of negroes who gradually lose their black color, and become as white as if they were the offspring of parents of another race. The "Manchester Memoirs" contain the case of a negro 40 years of age whose skin had so changed in two years that the narrator was convinced that all the black portions remaining did not exceed a square foot, and the change was then continuing very rapidly. The "Philosophical Transactions" contain the case of a negress in Maryland 40 years of age who had been turning white for 15 years, and had become in that time scarcely different in color from a European. Another instance is related in the "Philosophical Transactions" of a boy born in Virginia of black parents, who continued of his native color until he was three years of age, at which time a change began to take place, although the boy's health continued good. At first white specks made their appearance on his neck and breast, which soon increased in number and size so that from the upper part of his neck to his knees he was completely dappled. Dr. Barton relates the case of Henry Moss, a negro, in the state of Maryland, whose skin had undergone a complete change from a deep black to a clear and healthy white. The change commenced about the abdomen, and gradually extended over the different parts of the body, so that in seven years it had spread over a greater part of the skin. It had not a sickly or albino hue, as if from the effect of disease, but was of a healthy aspect. He had never suffered from disease, and during this change, which was gradual and

frequently irregular, he continued in robust health. A curious case is narrated by Dr. Hutchison of Missouri (now of Brooklyn, N. Y.) in the "American Journal of Medical Sciences" for January, 1852. The subject of this notice was a slave aged 45. He was born of black parents, and was himself perfectly black until the age of 12. At that time a portion of the skin an inch wide, encircling the cranium just within the edge of the hair, gradually changed to white, also the hair occupying that locality. A white spot next appeared near the inner canthus of the left eye, and from this the white color gradually extended over the face, trunk, and extremities, until it covered the entire surface. The complete change from black to white occupied about ten years, and but for his hair, which was crisped or woolly, no one at this time would have supposed that his progenitors had any of the characteristics of the negro, his skin presenting the healthy vascular appearance of a fair-complexioned European. When about 22, dark-colored or brown spots began to appear on the face and hands, being limited to those portions of the surface exposed to light. Thus it appears that the coloring matter that gives rise to the various hues in the complexion is sometimes produced in the skin of persons born white, and at others removed from those born black. Now it is hardly possible, in view of these facts, to suppose with Flourens that the discoloration which takes place in the skin of the white person is totally different in kind and has its seat in a different structure from that which produces the black or tawny hue in the colored races.—Microscopical investigations have done much to solve the doubt that hangs over this question. Henle, in examining the skin of the negro by the aid of the microscope, discovered, besides the order of cells usually found, others containing the black pigment which imparts the color to the African's skin. He found these last aggregated especially on those parts of the rete mucosum which project and correspond with the furrows of the surface of the cutis. Dr. Simon of Berlin took pains to ascertain whether the discolorations which occasionally take place in the skin of persons of European extraction depend upon the presence of similar cells filled with pigment; and in examining the discolored portions of such skins, as the areola around the nipple, he found that the discolorations depended on the presence of cells filled with pigment in the rete mucosum. The shape and size of these cells correspond with those described by Henle as existing in this portion of the skin of the African, and which imparts to it its peculiar color. Simon also examined many of those abnormal discolorations that take place in *nævi materni*, or congenital spots, moles, and summer freckles, and found in each that the coloring substance was contained in the rete. All of these discolorations are related therefore, Simon concludes, to the normal and natural colorations in the skin of the negro. The rete mucosum, which derives so much importance from its being the seat of the coloring matter that gives rise to the varieties of complexion observable among the different races of mankind, is found by later microscopical researches, and especially those of Kölliker, not to be a distinct structure, but to consist of the more recently formed parts of the epidermis, whose cells are not yet consolidated by the formation of horny matter in their interior. The pigment cells which secrete coloring matter, as first shown by Simon, are not readily distinguishable in the epidermis of the white races, except in certain parts of the body, as around the nipple, but are quite perceptible in the new layers of the epidermis of the negro. It was supposed by Simon that these cells gradually become flattened, and passing to the surface give the dark tint observable in the colored races. The examinations of Kölliker establish the fact that the cells containing coloring material do not change their place, but remain stationary in that portion of the epidermis in which they were first developed. Dr. Carpenter says: "The epidermis or cuticle covers the exterior surfaces of the body as a thin, semi-transparent pellicle, which is shown by microscopical examination to consist of a series of layers of cells, which are continually wearing off at the external surface and are being renewed at the surface of the true skin, so that the newest and deepest layers gradually become the oldest and most superficial, and are at last thrown off by desquamation. In their progress from the internal to the external surface of the epidermis, the cells undergo a series of well marked changes. When we examine the innermost layer we find it soft and granular, consisting of nuclei in various stages of development into cells, held together by a tenacious semi-fluid substance. This was formerly considered as a distinct tissue, and was supposed to be the peculiar seat of the color of the skin; it received the designation of *rete mucosum*. Passing outward, we find the cells more completely formed; at first nearly spherical in shape, but becoming polygonal where they are flattened one against another. Mingled with the epidermic cells we find others which secrete coloring matter instead of horn; these are termed pigment cells. The most remarkable development of pigment cells in the higher animals is on the inner surface of the choroid coat of the eye, where they have a regular arrangement, and form several layers known as *pigmentum nigrum*. The black color is given by the accumulation within the cells of a number of flat, oval, or rounded granules of extreme minuteness, which exhibit an active movement when set free from the cell, and even while enclosed within it." Quain and Sharpey say: "Many of the cells of the cuticle contain pigment, and often give the membrane more or less of a tawny color, even in the white races of mankind. The blackness of the skin of the negro depends

entirely on the cuticle. The pigment is contained principally in the cells of the deep layer or rete mucosum, and appears to fade as they approach the surface, but even the superficial part possesses a certain degree of color."—Exposure to light exercises a marked influence over the development of the pigment cells of the skin, and hence many persons become spotted with brown freckles under the stimulus of a summer sun. In the same manner the light skin of the European acquires a swarthy hue when exposed to a long continuance of the sun's rays in a tropical climate, which is due to a development of dark pigment in the cells of the cuticle. Bishop Heber, in his observations on India, says: "It is remarkable to observe how surely all these classes of men (white—Persians, Greeks, Tartars, Turks, and Arabians) in a few generations, even without intermarriage with the Hindoos, assume the deep olive tint, little less dark than the negro, which seems natural to the climate. The Portuguese have during 300 years' residence in India become as black as Caffres." "The hottest portion of the globe," says Dr. Pickering, "appears to be about 17 degrees in width, counting from lat. 27° N., and extends from the Atlantic to the Ganges. One third, perhaps, of this immense tract is inhabited by the white race, although under a physical aspect that would not readily be recognized by Europeans. The complexion, always dark, is in frequent instances sufficiently so to conceal a flush; indeed, the Malay brown complexion seems to preponderate, and I have seen Arabs of deeper hue who were apparently of unmixed descent. In short, the white race is here protean or polymorphous, and exhibits a diversity in feature and complexion that I have not found in the other races." Dr. Smith says that the influence of climate on the human complexion is demonstrated by well known and important events within the memory of history. From the Baltic to the Mediterranean the different latitudes of Europe are marked by different shades of color; and in tracing the origin of the fair German, the dark-colored Frenchman, and the swarthy Spaniard and Sicilian, it has been proved that they are all derived from the same parent stock, or at least from nearly resembling nations. The southern provinces of France, of Italy, of Spain, and of other European countries, are distinguished from the northern by a much deeper shade of complexion; thus, the traveller through Spain will discover that while the ladies of the province of Biscay possess fair complexions, those of Granada and other southern provinces are endowed with that dark, swarthy hue which the Spaniards consider as constituting one of the chief elements of beauty. The Georgians and Circassians, who are acknowledged to be the fairest people on the globe, when transferred to a residence in Constantinople lose their delicate complexion and gradually acquire a sallow hue, which in their descendants becomes a dark olive. But perhaps the most striking example is furnished by the Jews, who, by abstaining or being prohibited from intermarrying with other nations, form a distinct people in every quarter of the globe, and yet show noticeable shades of complexion in different climates. The native population of the United States furnish a strong illustration of the influence of climate over the complexion. Deriving their origin chiefly from the more northern nations of Europe, and especially from the English and Irish, whose complexions are remarkably fair, they are found to differ from their ancestors in this respect in a very material degree. A certain paleness of countenance, differing entirely from the marked white and red of the English, strikes the observant traveller at every step of his progress through the United States. The elevated temperature of the lowlands in Virginia and Maryland, especially near the seacoast, greatly contributes to impart a darkness to the complexion which, when associated with the paleness so common to the whole population of the United States, removes them in a most marked manner from their British ancestors. It is very easy to distinguish the natives of the eastern shore in Maryland, and of the counties contiguous to the ocean in Virginia, from the inhabitants of the more elevated districts in these states, as much by the marked sallowness of the complexion of the former as by their excitable temperament and spare habit of body. Going still further south, along the seacoast of Georgia and the Carolinas, it is not unusual to meet with individuals, especially among those much exposed to the influence of the sun, who are but a few shades lighter than the aboriginal tribes who formerly peopled these states. "If," says Dr. Barton, "these remarkable changes are wrought on the system in the term of a few years, we ought not to be surprised at seeing even the most opposite tints and features produced from the long and permanent operation of moral and physical causes." Yet, notwithstanding the influence exerted by heat in darkening the complexion, it is true that many light nations are found in the warmest regions, while there are dark ones resident in the coldest. Lord Kames, M. de Virey, and Prichard have quoted many instances of this kind. "We found," says Humboldt in his "Political Essay on New Spain," "the people of the Rio Negro swarthier than those of the lower Orinoco, and yet the banks of the first of these rivers enjoy a much cooler climate than the more northern regions. In the forests of [Venezuelan] Guiana, especially near the sources of the Orinoco, are several tribes of a whitish complexion, the Guiacos, Guajoribs, and Argues, of whom several robust individuals, exhibiting no symptom of the asthenical malady which characterizes albinos, have the appearance of true mestizos. Yet these tribes have never mingled with Europeans, and are surrounded with other tribes

of a dark brown hue. The Indians in the torrid zone, who inhabit the most elevated plains of the Cordilleras of the Andes, and those who are under lat. 45° S., have as coppery a complexion as those who under a burning climate cultivate bananas in the narrowest and deepest valleys of the equinoctial region." "Do we not in fact behold," says Virey, "the tawny Hungarian dwelling for ages under the same parallel and in the same country with the whitest nations of Europe, and the red Peruvian, the brown Malay, the nearly white Abyssinian, in the very zones which the blackest people in the universe inhabit? The natives of Van Diemen's Land are black, while Europeans of the corresponding northern latitudes are white; and the Malabars, in the most burning climate, are no browner than the Siberians." The temperature of a place, however, depends not only on its latitude, but on its elevation and its meteorological conditions. For these reasons the lines of equal temperature do not always agree with the same degrees of latitude, nor are they measured by the widest range in the thermometer. Now, although the elevation of temperature in Africa may not at any one time be greater than is sometimes observed in America, yet there can be no doubt that the annual amount of heat far exceeds that found in the tropical latitudes of the western continent. In measuring the effect of any particular climate upon complexion, therefore, it is necessary not only to determine its absolute degree of latitude, but also to ascertain what other causes are in operation tending to bestow a deeper or lighter shade upon the human countenance. It is a well known fact that the luxuriance of vegetation is not so much dependent on the intensity as on the mean quantity of heat; and the same law which operates in effecting a distribution of plants over the surface of the globe, independent of well defined lines of latitude, likewise exercises its influence in determining the intensity of shade observable among the different races of mankind. Those nations most exposed to the weather and furthest removed from civilization are, as a general rule, the darkest. Thus the South sea islanders, who seem to be of one family, vary in complexion according to the degree of their civilization. The Australians, who are savages, are black; The New Zealanders, half civilized, are tawny; the Friendly islanders are frequently of an olive color; while the people of Tahiti and the Society islands, who are the furthest advanced in civilization, are often possessed of a light complexion and flowing ringlets, and sometimes are considered really beautiful. The same fact is observable among persons of different degrees of cultivation in countries having complete and absolute divisions of rank. Thus not only are the nobility of France, Spain, Italy, Germany, and England easily distinguished from the peasantry, but the intermediate classes are as readily determined. An interesting fact connected with this subject is, that the children of those most exposed to the influence of the sun among the white races, and even the offspring of many who possess a tawny color, are as fair at birth as those of the most delicately complexioned parentage. The children of the Moors are born white, and acquire the complexion of their parents in after years. Russell says that the inhabitants of the country in the vicinage of Aleppo are naturally of a fair complexion; and among the women in the upper ranks of life this fair skin is preserved through life, while the inhabitants of that country are generally tinged with a shade which, although lighter than the negro, is deeper than that of the Telingan.—The division of mankind by Blumenbach into the five varieties of Caucasian, Mongolian, Ethiopian, American, and Malay, is, among other characteristics, largely founded on difference in complexion. The Caucasian is for the most part characterized by a white skin and red cheeks; the hair of a nut-brown, running on the one hand into yellow, and on the other into black, soft, long, and undulating. The Mongolian has a skin of an olive color, and black, stiff, straight, and sparing hair. The Ethiopian has a black skin, and black curly hair. The American possesses a skin of a copper color, with black, stiff, straight hair. The Malay has a tawny skin, and black, soft, curled hair. (See ETHNOLOGY.) Dr. Pickering, who has made very extensive observations upon different races, adopts a new classification. "I have seen in all," he remarks, "eleven races of men, and though I am hardly prepared to fix a positive limit to their number, I confess, after having visited so many different parts of the globe, that I am at a loss where to look for others. They may be enumerated conveniently enough in the order of complexion, beginning with the lightest. *a.* White: 1, Arabian; 2, Abyssinian. *b.* Brown: 3, Mongolian; 4, Hottentot; 5, Malay. *c.* Blackish brown: 6, Papuan; 7, Negrillo; 8, Indian, or Telingan; 9, Ethiopian. *d.* Black: 10, Australian; 11, Negro." This classification of Dr. Pickering is here introduced to show the importance of complexion as a characteristic of the different varieties of the human race. It will be observed that the color of the hair appears to be in a great degree connected with that of the skin; and it may be added that the color of the eyes likewise bears the same relation. Light hair is the usual accompaniment of a white and thin skin, while dark hair and a dark complexion are usually associated together.—Among all races there is a class termed albinos, whose bodies appear to be destitute of coloring matter, and who, besides a creamy-white skin, have white hair and pale, rose-colored eyes, owing to the absence of the pigmentum nigrum from the sclerotic coat of the eye. This renders them unusually sensitive to light. Werfer, in his description of those he saw among the inhabitants of the isthmus of Darien, says: "They see not well in the sun, poring in the clearest day, their eyes being

weak and running with water if the sun shines on them, so that in daytime they care not to go abroad, unless it be in a cloudy, dark day. Besides, they are a weak people in comparison with others, and not very fond of hunting or other laborious exercises, nor do they delight in such; but notwithstanding their being thus sluggish and dull in the daytime, yet when moonshiny nights come, they are all life and activity, running abroad into the woods and turning as fast by moonlight, even in gloom and shade, as other Indians by day." Dr. Davy, in speaking of an albino in Ceylon, where they are often seen, says: "The young albino 12 years of age, in England, and certainly in Norway, would not be considered peculiar, for her eyes were light blue, and not particularly weak, and her complexion fresh and rosy. She had considerable pretensions to beauty, and was not without admirers among her countrymen. The Indians are of the opinion that the white race were propagated from an albino, and there is a tradition among them to this effect."—However marked may be the influence of climate and surrounding circumstances upon the complexion, it is incompetent to produce such changes as to lead the ethnologist to mistake one race for another. The hue of the European, although it may exhibit a deeper shade under some circumstances than under others, is the same under the influence of the intense heat of the East Indies or the tropical climate of South America, and is entirely distinct from that of the natives of those countries. The three races which exist side by side in America are never merged in each other by mere contiguity, but continue separate and distinct except when a commingling of the races gives rise to a progeny that partakes of the character of both parents. The children of Europeans, of negroes, and of Indians, born in America, in the course of a few days after their birth begin to assume the complexion of their parents. Those of Caucasian parentage, whether natives of a high or low latitude, exhibit the fair complexion due to their origin, which may be retained by proper care through life; but those born of American or Ethiopian parents, however carefully guarded from the influence of the heat and sun, rapidly acquire the dark or tawny hue of the race from which they have sprung. Nor is the force of this position lessened by the observation of those travellers who have found the different tribes of the white race that have for centuries inhabited the tropics of a hue nearly as dark as that of the natives of the countries where they are found. A close examination in each of these cases would develop a marked difference between the shade of color of the white and that of the colored person, as distinct in character and as easily discerned as are the features that distinguish the one race from the other. The inferences to be drawn from these facts are: 1, that no essential anatomical difference exists between the skin of the white and colored races; 2, that climate, temperature, and exposure are competent to produce marked changes in the complexion; 3, that these changes under no circumstances proceed so far as to bestow the complexion peculiar to one race upon the individuals of another; 4, that children of white parents, under every condition of climate, are born fair; and 5, that the children of parents of colored races partake of the complexion of their parents from their earliest infancy.

COMPLINE, or **Complin** (Fr. *complies;* Lat. *completorium*, from *complere*, to complete, and in some liturgical books *complini*), in the Roman Catholic breviary, the complement of vespers or evening office, and the conclusion or last of the "daily" canonical hours, as distinguished from the "nocturnal" hours. According to Sozomen (*Hist. Eccl.*, iii. 13) and Cassian (*Inst.*, iii. 2), the psalms now recited at compline formed originally part of the vesper office. This is plainly indicated by St. Basil (*In Reg. Fus. Disp., interr.* 18), who says that "when the shades of evening begin to fall" we should sing the 90th psalm, *Qui habitat in adjutorio altissimi*, which is now the principal psalm of compline, while the hymn begins *Te lucis ante terminum.*

COMPLUTENSIAN POLYGLOT. See Bible.

COMPOSITE ORDER, one of the five orders of architecture, a combination made by the Romans of the Ionic and Corinthian styles, and hence also called the Roman order. It differs from the Corinthian chiefly in having upon the capital the volutes of the Ionic order; and its frieze and other of its members admit of a richer decoration. Among the principal examples of this order at Rome are the temple of Bacchus, the arches of Septimius Severus and of Titus, and the arch in the baths of Diocletian. (See Architecture.)

COMPOUND BLOWPIPE. See Blowpipe.

COMPRESSIBILITY, that property of matter which allows the volume of a body to be diminished by pressure, being a consequence as well as an evidence of porosity. The word porosity as used here does not signify the ordinary sensible porosity of bodies, such as is observed in a sponge or in wood, but that which has received the name of physical porosity. The physical pores are the exceedingly small interstices between the molecules of matter of which a body is formed, so minute in solids and liquids as to allow the molecules to remain within the sphere of cohesive attraction. Examples of compressibility are furnished by the reduction of liquids under pressure, and of compact masses of metal by hammering. The relative compressibilities of different bodies are readily ascertained by subjecting them to a given pressure and observing the diminution of volume resulting in each, care being taken that the temperatures are the same, because each degree of heat increases the repulsion between the molecules. Under the same pressure, a solid heated is larger than when cold. When bodies

are compressed sensible heat is always manifested, the force being converted to this condition. Gases and vapors are the most compressible of all bodies, and within certain limits their compressibility is uniform and in proportion to the compressing force, as enunciated in Mariotte's law. The forcing of water through the sides of a heavy hollow ball of gold in which the liquid was confined, in the attempt of the Florentine academicians to compress it, led to the long continued belief in the total incompressibility of liquids; but this property has been proved by Canton, Oersted, and others to exist in them as well as in gases and solids. Later experiments by Colladon and Sturm show that an additional pressure equal to that of the atmosphere caused mercury to diminish $\frac{1}{3,000,000}$ of its original volume, water $\frac{1}{300,000}$, and ether $\frac{133}{1,000,000}$.

COMPTON, a S. W. county of the province of Quebec, Canada, bordering on Maine, New Hampshire, and Vermont, and intersected by the Grand Trunk and St. Lawrence and Atlantic railroads; area, 1,380 sq. m.; pop. in 1871, 13,665, of whom 4,257 were of English origin or descent, 3,785 French, 3,282 Scottish, and 1,885 Irish. Its surface is diversified by several lakes, and a mountain range extends along its S. and S. E. border. The soil, drained by the head waters of St. Francis and Chaudière rivers, is moderately fertile. Capital, Compton.

COMPTON, Henry, an English prelate, born at Compton in 1632, died July 7, 1713. He was the youngest son of Spencer, second earl of Northampton, studied at Oxford, and after the restoration became a cornet in a regiment of horse. Afterward he left the army for the church, was ordained at the age of 30, and became bishop of Oxford in 1674, and bishop of London in 1675. Charles II. made him a member of his privy council, and intrusted to him the education of his nieces Mary and Anne. He was distinguished for his hostility to the church of Rome. After the accession of James II., Dr. Sharp, rector of St.-Giles's-in-the-Fields, having preached several sermons vindicating the church of England against the papacy, became highly obnoxious to the court, and Compton was required by a royal order to suspend him. His refusal to obey was made the ground of his own suspension. He was restored to his see at the time of the revolution, and, together with the bishop of Bristol, made up the majority of two in the house of lords for filling the vacant throne. He performed the ceremony of the coronation of William and Mary, and was afterward appointed one of the commissioners for revising the liturgy. During the reign of Anne he was put on the commission for the union of England and Scotland. The reconciliation of dissenters with the church of England was one of his favorite projects.

COMPURGATORS, in Saxon law, persons who appeared to join to the oath of an accused party their own oaths to their belief in his innocence. Compurgators were to be twelve in number, from the neighborhood of the accused; and to this practice of purgation has been referred the origin of jury trial. The process was also admitted in case of simple contract debts. The like practice of purgation in the case of clerks-convict continued in England until abolished by statute 18 Elizabeth, c. 7.

COMSTOCK, John Lee, M. D., an American author, born at Lyme, Conn., in 1789, died in Hartford, Conn., Nov. 21, 1858. He studied medicine, and served as an assistant surgeon in the war of 1812. At the close of the war he left the army and settled at Hartford in the practice of medicine. Soon after, his attention was turned toward the compilation of school books. He wrote elementary treatises on natural philosophy, chemistry, mineralogy, botany, geology, physiology, natural history, and physical geography, and an essay on gold and silver. Some of his works were only compilations; but he made considerable attainments in natural science, constructed most of the apparatus he used, and prepared nearly all the drawings for the illustrations of his works.

COMTAT-VENAISSIN, an ancient territory of S. France, surrounded, with the Comtat d'Avignon, by Dauphiny, Provence, and Languedoc, from which it was separated by the Rhône. It passed from the Romans to the Burgundians and the Franks, in the 11th century to the counts of Arles, and in the 12th to the counts of Toulouse. The latter were dispossessed for a short time by the crusaders in the following century, but were reinstated under Count Raymond VII., whose daughter Jeanne married Prince Alphonse, a brother of Louis IX. After his death Philip III. of France gave it to Pope Gregory X. (1273). Its name was derived from Venasque, the ancient capital, which was supplanted by Carpentras. It remained in the hands of the popes almost uninterruptedly till 1791, when it was annexed to France, together with Avignon, as part of the department of Vaucluse.

COMTE, Auguste, a French philosopher, founder of the system of positivism, born in Montpellier, Jan. 12, 1798, died in Paris, Sept. 5, 1857. He received his education at the polytechnic school of Paris, where he became a teacher in 1832. He gave his principal attention to mathematics and the physical sciences, but was not indifferent to moral inquiries, and was attracted by the socialism of Saint-Simon. This was in 1815, and Comte, though the youngest, soon became one of the most prominent of his disciples. In 1820 he was called upon to prepare an exposition of the doctrines and objects of the school, which he did in a little work called the "System of Positive Politics;" but Saint-Simon saw at once that his pupil had adopted another idea than his, and that positive politics was not socialism as he understood it. His principal objection was that Comte overlooked entirely the religious or sentimental side of human nature. In 1825

the school divided; Enfantin, Bazard, Augustin Thierry, Chevalier, and others, proceeding to organize a system of propagation for the opinions of their master, and Comte taking to his own course. In 1826 he was arrested in his speculations by what he denominates "a cerebral crisis," but which his physicians described as a brain fever, terminating in insanity. He soon recovered, and devoted the rest of his life to teaching mathematics, at first as a professor in the polytechnic school, and to the gestation of his new schemes of thought. In 1830 he began the publication of his chief work, the *Cours de philosophie positive*, in six large volumes, which was not completed till 1842. It was filled with novel speculations, but attracted little or no attention, and it was not till 16 years after the publication of the first volume that it was noticed in any leading review. In 1843 Comte published a *Traité élémentaire de géométrie analytique*, and in 1854 a *Traité d'astronomie populaire*, both works of a strictly scientific cast. Meanwhile he had quarrelled with his brother professors, the result of which was that he lost his official employment. He then supported himself by private teaching, by Sunday lectures to a small audience, and by the voluntary contributions of a little knot of disciples. In 1848 a *Discours sur l'ensemble du positivisme* appeared, recapitulating his doctrine as a whole, and giving a brief outline of what it proposed for the future. But it was only a prelude to a work printed in 1851–'4, called the *Système de politique positive* (4 vols.), which gave the final view of his doctrine. A short *Catéchisme positiviste*, published in 1852, is a mere summary exposition of the teachings of the larger work. In the interval between the publication of the *Cours* and the *Système* he fell in love with a married woman; and his affection for her, intensified by her sudden death, convinced him that the old criticism of Saint-Simon was true, and that the religious or sentimental side of human nature was not to be despised. He died of hypertrophy of the heart, and was buried in the cemetery of Père la Chaise.—Comte's scheme of thought is so immense that no attempt to describe it in an abridgment can do justice to it; yet a few words in regard to it are necessary. His first position is that the human mind, in its progress historically and individually, passes through three stages of development: 1, the theological, in which all the phenomena of nature are imputed to the active agency of the gods; 2, the metaphysical, in which the gods are made to give place to certain abstract entities and quiddities called "nature," "harmony," "number," &c.; and 3, the positive or scientific, in which it is discerned that man can know nothing of causes, and is only able to refer phenomena to their general laws of existence or succession. Arrived at this stage, science is born, and knowledge, no longer baffled by the inscrutable or misled by the imaginary, advances, through one generalization after another, to a comprehensive perception of the universe as a whole. His second position is, that in this advance it proceeds in a regular hierarchical order, from the simple to the complex, or from the most elementary relations of numbers to the highest and deepest complications of society and life. This order of the sciences he arranges as follows: 1, mathematics, the most general and simple of all, dealing only with numbers and magnitudes; 2, astronomy, the application of the principles of mathematics to the phenomena of the celestial sphere; 3, the application of mathematics and astronomy to the phenomena of the terrestrial sphere, or general physics, including heat, light, optics, electricity, &c.; 4, chemistry, the science of the phenomena of the interior of bodies or of molecular changes; 5, biology, the science of the phenomena of individually organized being, or vegetable and animal life; 6, sociology, the science of the phenomena of corporate or social life, which, presupposing and containing all the former, is the queen of all the sciences. Having finally reached his goal, or sociology, he undertakes, as his third position, a demonstration of the statics and the dynamics of social life, or of the fundamental principles of order and liberty. The first element of order is the family; the second, the community, composed not of individuals but of families, and coöperating to a certain extent in their employment; and the third, the government or state. Liberty is the effect of this harmonious organization, and progress the development of it, by means of the conquest—1, of material nature; 2, of the lower propensities by the higher intellectual faculties; and lastly, of the selfish passions by the social affections. To this point, the mere superiority of the social affections, Comte had gone in his first work; but after his love experience, and upon a maturer consideration of the nature and objects of life, he saw that a deeper question remained untouched. It was that of religion, which he conceived to be the complete harmony of human existence, individual and collective, or the universal unity of all existences in one Great Being, whom he calls Humanity. Religion, at first spontaneous, dissipates itself in fetishism and polytheism; next, inspired, it lifts its thoughts to the vague abstract unity of God; and finally, revealed or demonstrated, it finds its object in a true, living, and ever active being, which is humanity. This alone is the genuine end and object of all worship, and to this every effort of the good man should converge. But, as eminent individuals, Moses, Socrates, Mohammed, &c., are manifestations of the Grand Being, it is not improper to pay to them a high yet qualified respect. Accordingly, Comte arranged the formula of a worship of humanity by means of homages and festivals to its most illustrious representatives. He even reformed the calendar in view of it, and called the months after the names of illustrious benefactors, and the

weeks after others.—See "Comte's Philosophy of the Sciences," by G. H. Lewes (London, 1853); "The Positive Philosophy of Auguste Comte," by Harriet Martineau (1854); *Cours de philosophie positive*, with a preface by É. Littré (6 vols. 8vo, Paris, 1864); *Notice sur l'œuvre et sur la vie d'Auguste Comte*, by Dr. Robinet (2d ed., 1864); *Auguste Comte et la philosophie positive*, by É. Littré (1864); and "Comte and Positivism," by J. S. Mill (1865).

COMUS, in the later Greek mythology, the god of festive mirth. He is represented as a winged youth, intoxicated and languid after feasting, his head sunk on his breast, his legs crossed, his countenance flushed with wine. In one hand he feebly grasps a hunting spear, in the other an inverted torch.

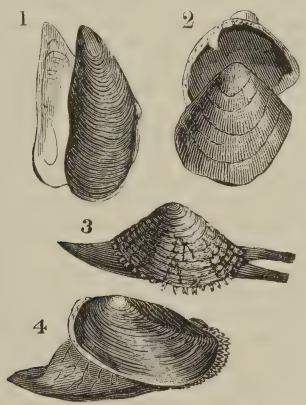
CONANT. I. Thomas Jefferson, an American Biblical scholar, born at Brandon, Vt., Dec. 13, 1802. He graduated at Middlebury college in 1823, pursued philological studies for two years in New York, was for a short time tutor in Columbian college at Washington, and afterward professor of languages in Waterville college, Maine. He resigned this post in 1833, and took up his residence near Boston, where he could more advantageously prosecute his studies in the oriental languages. He had become convinced of the necessity of a fresh translation of the Scriptures, which should fully represent the original text; and to this his life has been chiefly devoted. In 1835 he accepted the appointment of professor of Biblical literature and criticism in the Baptist theological seminary at Hamilton, N. Y., which he held till 1850, although two of the intervening years were spent in Europe, mainly in Halle and Berlin. While professor at Hamilton he translated the Hebrew grammar of Gesenius, with the additions of Rödiger, a work which has become the standard text book in America and Great Britain. In 1850 he became professor of Biblical literature in the theological seminary of Rochester, but resigned in 1857, and removed to Brooklyn, to devote himself exclusively to the labor of Biblical revision, in the service of the American Bible union. His work in this department consists of revised versions, with critical and explanatory notes, of "The Book of Job" (1857), "The Gospel by Matthew" (1860), "The Book of Genesis" (1868), "The Book of Psalms" (1868; also, with some additional notes, in the American edition of Lange's "Commentary," 1872), and "The Book of Proverbs" (1872). In 1860 he published "Βαπτίζειν: its Meaning and Use philologically and historically investigated." He is now (1873) a member of the Old Testament company of the American committee, cöoperating with the committee of the convocation of Canterbury, England, in the revision of the authorized English version of the Bible. **II. Hannah Chaplin,** wife of the preceding, born at Danvers, Mass., in 1809, died in Brooklyn, N. Y., Feb. 18, 1865. She was the daughter of the Rev. Jeremiah Chaplin, president of Waterville college, and was married to Mr. Conant in 1830. She was a frequent contributor to literary and religious periodicals, and in 1838 became editor of the "Mother's Journal," a monthly periodical. In 1844 she translated "Lea, or the Baptism in the Jordan," from the German of Strauss, the evangelical court preacher of Berlin. In 1850–'52 she translated the commentaries of Neander on the Epistle of Paul to the Philippians, on the Epistle of James, and on the first Epistle of John. In 1855 she wrote "The Earnest Man," a biographical sketch of the missionary Judson; and in 1857 translated from the German "The New England Theocracy," a sketch of the early ecclesiastical history of New England, by Uhden. Her most elaborate work is "The English Bible; a History of the Translation of the Holy Scriptures into the English Tongue" (New York, 1856).

CONCAN, North and South, a maritime tract of the Bombay presidency, British India, extending from the Portuguese settlement of Goa on the south to the river Damaun on the north, bounded W. by the Indian ocean and E. by the Ghauts; area, about 1,000 sq. m.; pop. about 1,500,000. The surface is rugged, and the mountains on the E. frontier attain in some places an elevation of 4,700 ft. Deep ravines and thick forests occupy the E. portion, whence the surface slopes by degrees toward the seacoast, where the mean elevation is not more than 100 ft. Part of the country is fertile, populous, and susceptible of high cultivation. One of the most remarkable characteristics of the climate is the violence of the monsoon rains, the mean annual fall in some places amounting to 239 inches. There are numerous bays and harbors, which for ages afforded secure retreats to pirates. The Great Mogul maintained a fleet for the purpose of checking them, the Portuguese frequently attacked them, and from the year 1756 numerous expeditions from Bombay were despatched against them by the British; but the piratical system was not wholly suppressed till 1812. When the Hindoos conquered the country they gave it to a tribe of Brahmans, from whom it was wrested by the Mohammedan kings of Bejapoor. In the 17th century it passed into the possession of Sevajee, the founder of the Mahratta empire. Toward the close of the same century the pirate chief Conajee Angria established a kingdom here, extending 120 m. along the coast, and inland as far as the Ghauts. In 1756 most of this territory was restored to the peishwa by the united British and Mahratta forces. North Concan, which is inhabited by wild uncivilized tribes called Bheels, was once held by the Portuguese. The territory was ceded to Great Britain in 1817. South Concan passed under British rule, partly by cession, partly by conquest, in 1818.

CONCENTAINA, a town of Spain, in the province and 28 m. N. of the city of Alicante; pop. about 6,600. It has manufactures of linen,

woollen, paper, and soap, and an annual fair which is one of the largest in Spain.

CONCEPCION. **I.** A S. province of Chili, bounded E. by the Andes and W. by the Pacific, and having the river Itata on the north and the Biobio on the south; area, about 3,600 sq. m.; pop. 155,382. The soil is fertile and the climate delightful. The cereals and various kinds of fruits are produced in abundance. Among the chief exports are timber, lumber, hides, salted beef, and tallow. Coal of an inferior quality is mined in large quantities. **II.** The capital of the province, situated on the right bank of the Biobio, 7½ m. from its mouth, and 270 m. S. S. W. of Santiago, in lat. 36° 49′ 30″ S., lon. 73° 5′ 30″ W.; pop. about 15,000. It is a well built city, with wide streets crossing at right angles. Near the centre is a square with a fine fountain. Among the principal buildings are a handsome cathedral, a number of churches and free schools, an orphan asylum, a lyceum, theatre, prison, hospitals, and barracks. It is the seat of a bishop. Its port, Talcahuana, about 12 m. distant, on the S. W. side of Concepcion bay, is one of the best in Chili. It has been rebuilt entirely since the earthquake of 1835, and now contains about 5,000 inhabitants, and a number of churches and schools. A railway from Talcahuana to Chillan, 112 m., now constructing, will materially increase its importance. The bay of Concepcion is shut in by the island of Quiriquina, on each side of which is a good channel, and furnishes an extensive and safe anchorage.—Concepcion was founded by Pedro Valdivia in 1550, on the S. side of the bay. It was burned by the Araucanians several times, and suffered severely from earthquakes. After the earthquake of 1751 it was rebuilt on its present site. In 1823 the Araucanians again destroyed a part of it, and it was nearly ruined by the earthquake of 1835.



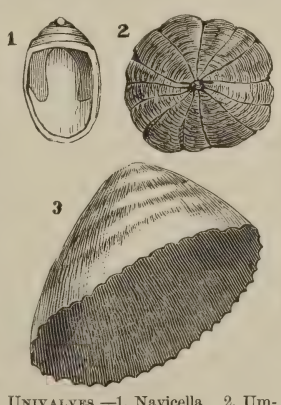
CONCH (Lat. *concha*, a shell), a name given to many univalve shells, of the families *strombidæ* or wing shells, *pyrulidæ* or fig shells, *fasciolaridæ* or band shells, &c. The name is also applied to the genus *triton*. The first named make curious egg cases, like flattened disks, attached in considerable numbers to a string on one side; the strings are sometimes two feet long, and are the favorite food of many carnivorous mollusks. These animals were doubtless eaten by the American aborigines, as their shells are numerous in the Florida shell heaps, and, though very tough, they are now eaten by the poor. Some of the shells are valuable for making cameos; and the South sea islanders use the sea conch (*triton*) as an instrument of music, blowing into the shell through the broken apex, thereby producing a loud and mellow sound. It is a species of sea conch which is represented as used by the god Triton. In many rural parts of the United States conchs of the genus *strombus* are used in place of dinner bells or tin horns, to call persons from a distance.

CONCHA. **I. José de la,** marquis of Havana, a Spanish soldier and statesman, born in Cordova de Tucuman, Buenos Ayres, in 1800. He took part in the war against the patriots in South America and against Don Carlos in Spain, became lieutenant general in 1839, and was captain general of the Basque provinces from 1843 to 1846. About this time he was placed at the head of the Spanish cavalry, and in 1849 was appointed captain general of Cuba, where he distinguished himself by his energy and the reforms he effected. He was removed shortly after the insurrectionary attempt of Gen. Lopez in 1851, and on his return to Spain published a valuable statistical work on Cuba. He joined his brother in opposing the government, and was banished from Spain in January, 1854. Subsequent to the July revolution of the same year he was reappointed captain general of Cuba, but was recalled on the return of Narvaez to power in 1856. He was subsequently senator, ambassador in Paris, and member of the Miraflores cabinet. On the outbreak of the revolution of September, 1868, he was appointed by Queen Isabella prime minister, and exercised the office until she crossed the frontier into France, when he followed her into exile. **II. Manuel de la,** marquis of Douro, brother of the preceding, born in Madrid in 1794, died June 28, 1874. He fought in early life against Napoleon and the revolted Spanish colonies in South America, and afterward against Don Carlos. As a member of the cortes, he gave his support to Maria Christina and Isabella, and successively to the administrations of Espartero and Narvaez. In 1843 he was commandant in Valencia and Murcia, and in 1844 captain general of Catalonia. In 1847, during the complications with Portugal, he was put in command of 6,000 men, and took possession of Oporto, by which victory he earned his title. In the same year he escorted Maria Christina to Paris, and on his return to Madrid resumed his seat in the cortes, where he was a conspicuous member of the ultra conservative party. Subsequently he was reappointed captain general of Catalonia. Having issued at the end of 1853, in concert with O'Donnell and Bravo Murillo, the famous protest against the policy pursued by the government, he was banished in January, 1854, and repaired to Paris; but he was recalled by the revolution of July of that year. He was made inspector general of cavalry and marshal; but in 1856, when Narvaez came again into power, he was compelled to relinquish his positions. In 1874 he commanded the army against the Carlists, and was killed in the battle of Estella. A work by him on infantry and cavalry tactics is the accepted text book in Spain.

CONCHAS. See Conchos.

CONCHIFERA (Lat. *concha*, Gr. *κόγχη*, a shell, and *fero*, to bear), a class of mollusks including all the bivalve shells, as oysters, clams, scallops, &c.; they were called *lamellibranchiata* by De Blainville. They are next to the univalves

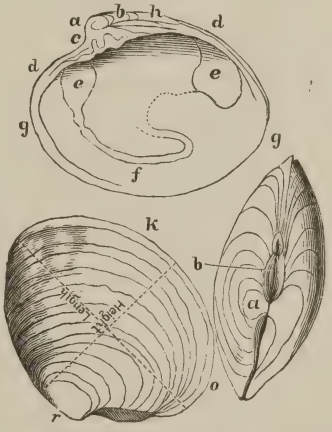
in variety and importance, and are invariably aquatic. They are all inhabitants of the sea, excepting a few widely scattered genera, live on every coast, and are found in every climate. The shells of the bivalves are united at the back by an elastic ligament and articulated by a hinge, which is sometimes furnished with teeth shutting by the side of each other and acting much like the common butt hinge. The valves are closed by strong muscles which pass from one valve to the other, and when these are relaxed the shells open spontaneously by the contraction of the cartilage. After the death of the animal, when the muscles lose their power, the elasticity of the ligament causes the valves to gape wide, more so than during the life of the mollusk. (See CONCHOLOGY.) The mantle, which is a conspicuous part of the animal, is a broad membrane which lines all the interior of the shell and encloses the whole body. Its edges are more or less fringed, and are either free, partly united, or entirely so, excepting a passage for the foot before and for the siphons behind. The foot is a muscular mass which may be protruded from the shell, and serves as the organ of motion. In *nucula* and some others the foot is deeply cleft, and capable of expanding into a disk like that on which the snail glides; while in the mussel, pearl oyster, and others, which habitually spin a byssus or thread of fibres by which they attach themselves permanently to substances, the foot is finger-like and grooved, and serves only to mould and fix the threads of which the byssus is composed. The branchiæ or gills are arranged somewhat like ruffles behind the foot, enveloping the abdominal mass. These are the respiratory organs, but they serve also another and very important purpose. Firmly fastened to rocks and other substances, or at best moving slowly and awkwardly in their muddy or sandy beds, these animals have not the power of following their prey, nor are they furnished with the means of seizing it, but the branchiæ convey to the mouth whatever particles the current brings, whether organic or inorganic, animal or vegetable; upon these the mollusk lives. The water is furnished to the branchiæ by one siphon, while another serves as a passage for the excrement. The branchial siphon has its orifice surrounded by a double fringe. When unmolested, a current flows steadily into the opening of this siphon, while another current rises up from the exhalant tube. The burrowing species have a strong foot, with which they bore into the sand and clay upon the shore so as to entirely conceal themselves. They never leave these abodes, and often become fossilized in them. The *teredo* or ship worm, and some other borers, which were formerly included among the univalves and multivalves, are now arranged in this class. The interior of the shell is marked with characters derived immediately from the shellfish, and affording a surer clue to its affinities than those which the exterior presents. The structure of the hinge characterizes both families and genera, while the condition of the respiratory and locomotive organs may be to some extent inferred from the muscular markings.



1. Mussel. 2. Nucula. 3. Venus verrucosa. 4. Anodon anatinus.

CONCHO, a W. county of Texas, bounded N. E. by the Colorado river, W. by Bexar district, and intersected by the Rio Concho and other streams; area, 1,025 sq. m.; yet unsettled. The surface is broken and rocky. Timber is scarce. The climate is dry and salubrious.

CONCHOLOGY (Gr. *κόγχη*, a shell, and *λόγος*, a discourse), the science which treats of the testaceous parts of the mollusca. Formerly these were made the basis for classifying the animals to which they belong; but the enlarged study, introduced by Cuvier, of the anatomical structure of the bodies contained within the shells, has developed an apparent want of correspondence between the latter and the organization of the more important parts, upon which the habits and true character of the animal must mainly depend. (See MOLLUSCA.) In the old classification, molluscous animals possessed of the same peculiarities of internal structure were widely separated by the differences of their external covering; some animals, as the cirripedes, comprising nearly all the old division of multivalves, were included with the mollusca because of their shelly covering, and thus they continued until their structure at last was found to refer them to the articulata; and some mollusca possessed of no shell, as the nudibranchs, would properly be excluded from the arrangement that comprised others hardly differing from them, except in being provided with this appendage, or perhaps but a poor apology for it. And then, as some species have the faculty of leaving and returning to their shells, it might occur, in ignorance of the relations of each part to the other, that the shell should be referred to one department and the body to another of the animal kingdom. Indeed, by reason of the changes of form and color that take place in the growth of some shells, the same species have been described at different ages of the individual under different names.



But though the important divisions of the mollusca are now based on their internal organization, the study of the shells is nevertheless not to be neglected in the pursuit of the general science of malacology, or the study of the mollusca; for the minor divisions into species are still generally controlled by differences in the forms of the shell; and in the important department of palæontology, it is only the outer coverings of the ancient mollusca, or casts of these in more durable materials, that are presented to us, by which we may determine their character.—Shells consist of carbonate of lime secreted by the animal, and intermixed with some animal matter; they are usually heavier where calcareous formations prevail, the mollusca which bear them also being more abundant than in granitic and other districts deficient in lime. The secretion is first of an albuminous matter through the pores of the outer mantle of the embryo mollusk; this is generally succeeded by an admixture of crystalline particles of carbonate of lime; new layers form beneath these, and the shell gradually gains thickness and extension. In the species in which it is least developed it appears as a hollow cone or plate, which serves as a protection to the breathing organ and heart. The mantle it covers in other species is in part the same important organ. The protuberances and ridges seen on many univalve and bivalve shells appear in the course of their growth by the margin of the mantle turning out at a considerable angle, and thus building up a plate in this position for a certain distance. This growth then ceases, the mantle retracts, or may be regarded as changing itself into the shelly layers, and then it extends in the original direction, carrying out the shell with it, till it turns again to form a second plate or ridge; and so the process goes on. The spines upon shells are produced by the mantle sending out from its margin tentacula, which secrete from their surface the calcareous matter, and thus form slender tubes. These become solid, as the fleshy matter, while it retracts and is absorbed, continues still to deposit the shelly layers. As each successive layer in the growth of shells extends beyond the line of the next older layer, the edges of these must appear upon the outer surface as marked lines of growth. Many mollusks possess the power of altering and enlarging their shells to adapt them to their growth, which they appear to do as if by an intelligent will. Thus the murices remove the spines that interfere with the extension of the shell; and others enlarge the aperture, when it has become too contracted for the body, by wearing away or dissolving its walls. The growing *cypræa* removes the inner wall of its shell, and extending its mantle around upon the outside, adds there, in successive layers, more than was taken from within. The shell not only thus changes in size, but the form of the adult becomes altogether different from that of the young. The distinguishing marks of shells are the number of parts of which they are composed, and their peculiar forms and prominences. They possess also different textures and various colors, often of great beauty. Some consist of a single piece, as those univalves which are not provided with the horny or calcareous operculum, such as is attached to the posterior part of the foot of other species, and which, when the foot is drawn in, serves to close the aperture as with a tight and perfectly fitting cover. In these the shell is in two pieces; so also is it in most of the bivalves, and the resemblance of the arrangement has led some conchologists to suppose that the operculum may be regarded as the equivalent of the dextral valve of the conchifera; but the anatomical structure forbids this conclusion. In the *terebratula* the shell is in three parts, and in some of the pholades and chitons it is in four or more. The peculiar forms of the aperture in some of the univalves are found to bear constant relations to the internal organization of the animal, and so far are therefore to be relied on as indicative of its habits and character. Such are the grooved and notched siphons in some of the spiral univalves peculiar to marine mollusca, which breathe by two gills furnished with a fleshy tube for supplying to them the water. The textures of shells are described as porcellanous, pearly or nacreous, fibrous, horny, and some are glassy and translucent. These textures are produced by the different manner in which the particles of mineral and animal matter are arranged, which is best exposed when the shells are partially decomposed by the disappearance of the animal substance, a condition often met with in fossil shells. In some of them the complicated arrangement of the three strata of plates, which make up the porcellanous structure, is exhibited in the broken edges of the cypræas, cones, &c. The outer and inner layers present the edges of the plates to the surface, while those of the middle one lie in groups at different angles. Each plate is composed of minute prismatic cells, arranged at angles of 45° with the plane of the plate, and these meet the cells of the adjoining plates at right angles. The animal matter of the porcellanous shells is soluble gelatine. The pearly shells are in alternating layers of very thin albuminous membrane and carbonate of lime, which by their minute undulations give the pearly lustre. This structure is the least permanent, and in some geological formations the shells that were provided with it have disappeared, leaving only their casts, while those of fibrous texture are preserved unchanged. This texture is produced by an arrangement of prismatic cells of carbonate of lime, which extend continuously through the successive layers that make up the shell. It is well exhibited in the heavy fossil *inoceramus*, which sometimes is found falling into fibrous blocks, the grain transverse to the surface of the shell. The oyster shell, in which the prismatic cells are irregularly ar-

ranged in the successive layers, separates into plates parallel with its surface—an example of laminated structure. In the *brachiopoda* the structure is so peculiar that it may be detected in the smallest fragment of shell; it consists of elongated and curved cells matted together, and often perforated by circular holes arranged in quincunx order. Colors, however beautifully exhibited upon the surfaces of shells, are to them no more distinctive features than to the minerals and flowers upon which they are also brilliantly displayed. They are most richly developed upon those surfaces most exposed to the light, and in the class of shells that inhabit shallow waters. In some instances they have proved as permanent as the shell itself, being preserved in a few of the fossils of various geological formations, even as old as those of the Devonian period. The color is usually limited to the surface beneath the epidermis, which is the membrane of animal matter coating the entire shell, and protecting it from the action of destructive chemical agents. But some of the shells of porcellanous texture present different colors in adjoining layers, a peculiarity which adapts them for the carved work in colors described in the article CAMEO.—The shells of a single piece appear in various forms; most of them are in spiral convolutions, which form logarithmic curves. In some the spire is wound around an axis called a *columella*, which is entirely concealed within the whorls; in others these wind about without coming in contact, the shell then resembling a corkscrew. Some are smooth conical bodies, terminated at the base of the cone by an insignificant spire, and with a long aperture on one side. In some the spiral form is very prominent in the young individuals, and is afterward entirely concealed under the successive layers of growth. In a few instances the convolutions are so flattened that no conical form is produced. The argonaut is an example of the last, a shell almost as delicate as paper, and so light as to be no impediment to the animal's rising to the surface by means of its distended air cells. The *haliotis* (sea-ear) is also an example of a very flat and in this instance obscure spire. The aperture of this shell is open, resembling the ear in form, whence its name. To the animal the shell is a covering shield, which protects him as he draws it down, and holds by his broad foot firmly to the rock. Many other

UNIVALVES.—1. Navicella. 2. Umbrella. 3. Patella.

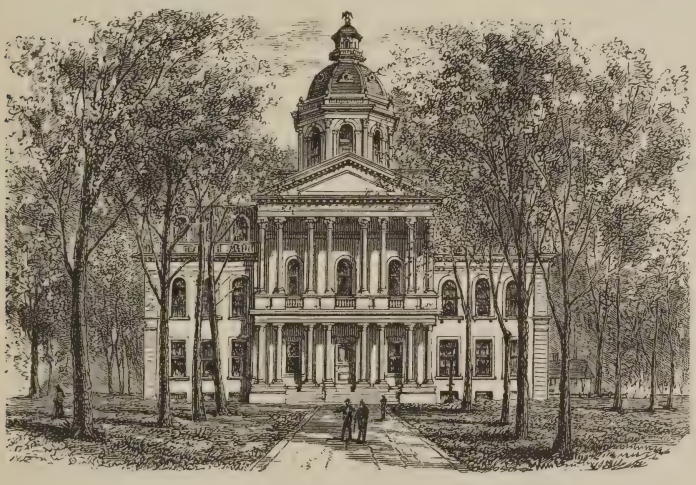
mollusca similarly provided are distinguished by shells shaped like a shield, as *umbrella;* or like a boat, as *navicella;* or of more conical form, as the *patella* or limpet. The univalves take also the form of a tube open at each end.—In describing shells, they are supposed to be in the position which the animals assume when in motion and progressing from the observer. The aperture of the univalves is downward, and the spire points backward and upward; the two sides are distinguished as right and left. The whorls wind obliquely from the apex of the spire from left to right in the greater number of species; those in which the direction is reversed are known as reverse or sinistral shells. Individual exceptions occur in the species of each group. Bivalve shells of the class *conchifera*, in which all are included that breathe by two pairs of gills, take when in motion a position with the hinge of the valves upward. Two prominences called the umbones are observed, one on each valve bending toward each other; the beak or apex of each of these corresponds to the apex of the spire of the univalves. It often inclines toward one end of the shell; this is always the anterior extremity, and the opposite the posterior. The latter is also marked in many bivalves by a notch or sinus in the pallial impression upon the inner surface of the shells, always opening, when it occurs, toward this extremity. The pallial impression is the mark of the margin of the mantle where it was attached to the shell. The position of some bivalves, as the large scallops, oysters, &c., is indicated only by the large muscular impression which is always on the posterior end unless it be between the umbones. The bivalve being then placed in its natural position for progressing from the observer, the valves are designated, one as the right, the other as the left. If the two be of the same size and

BIVALVE SHELL.—*a*, *a*, bosses; *b*, *b*, hinges; *c*, principal teeth; *d*, *d*, lateral teeth; *e*, *e*, muscular impressions; *f*, pallial impression; *g*, *g*, sides of the shell; *h*, ligament; *k*, ventral edge; *o*, front edge; *r*, umbo.

shape, as is the case in the unattached conchifera, the shell is said to be equivalve; but when one valve is attached to a foreign body, this is larger and deeper than the other, and the shell is said to be inequivalve; if one end be longer than the other, the shell is inequilateral. This measurement is made along the horizontal line of greatest length from each extremity to the vertical line dropped from the highest point of the umbones to the base. The anterior end is usually found to be shorter than the posterior. The upper margin is called the dorsal, and the lower the ventral. The breadth is the length of the vertical line from the dorsal margin to the base, and the thickness is the distance between the valves when closed. The valves may join closely together, or gape open at one or both ends, or even be furnished with a vertical opening by corresponding notches in the margin of the valves. These peculiarities of the form of the shell have relation to the internal organization of the animal, the openings being one for the purpose of allowing the protrusion of the foot for propelling the shell, another for the byssus by which it is firmly anchored, and another for the long siphon, the respiratory organ, which serves to inhale the water to be filtered by the gills, and then to pass it back. Bivalve shells are strongly marked on their inner surface, near the dorsal margin, by the depressions for the muscles which draw the valves together, and some present prominent apophyses for the attachment of these adductors. The shells also bear the impressions of the attachment of the foot, byssus, siphons, and mantle. But the most important marks are the articulations of the hinge, called teeth. These, by their different numbers and positions along the dorsal margin, serve as distinguishing marks of species, and even of genera; a distinction to which they are properly entitled from the fact that their varying forms indicate corresponding changes in the organization of the soft parts. The ligaments which hold the valves together are an external horny one lying behind the umbones, which is stretched by the closing of the valves, and an internal short fibrous one, which is compressed endwise as the valves are drawn together by the adductor muscles. As these are relaxed by death or otherwise, the shells are pushed partly open by the elasticity of the cartilage. The marks upon the inner surface of the valves left by these organs are important features in the description and classification of bivalve shells.—In the embryo of these animals the umbones are the first formed portions of their shelly covering. In most genera this is carried out with the growth of the body, so as always to serve as its complete protection; but in others it attains to the extent of only a partial covering, and in these instances other curious provisions are made for completing the necessary defence. The teredos are slender worm-like animals, that sometimes attain a length of 2½ ft., and one species even reaches 3 ft. By close observation only are the two shells perceived at the larger extremity of this long siphonal tube. They cover the visceral organs, but admit between them in front the fleshy foot, by means of which the creature is able to burrow into wood. Here he excavates long tubes adapted to his form, and finishes them with a smooth calcareous lining, thus providing an artificial covering for the unprotected portion of the body. Securing himself permanently to the inner extremity, his communication without is thereafter only through the siphonal tube. The pholades burrow into limestone and other stony substances which are less hard and tenacious than their own valves; other shells even are penetrated by them. The front portion of these is ribbed like a rasp, and is thought to answer the purpose of one in forming cavities. The whole shell is of unusual hardness, its structure more resembling that of aragonite than of calcareous spar. Being thin and without ligaments, it is strengthened by accessory valves upon the dorsal margin. In some attached bivalves, as the oyster, the embryonic umbo often takes the form of the surface to which the valve is fastened, and this form is afterward retained. With the growth of the animal the original shield loses its importance, and as in the univalves the spire, which corresponds to the umbo, is often deserted, and becoming dead and brittle falls away (in which case it is said to be decollated), so in the bivalves the umbones wear out and the layers of shell scale off, leaving the summit ragged and unsightly; in this condition they are said to be decorticated. The fresh-water univalves and bivalves are especially subject to this erosion. The injury that might result from this removal of the shell is obviated in some cases by the deposit of new layers within, or by the construction of partitions, or, as in some tubular shells which continue to advance upward with the growth of the coral that encloses them, by filling the deserted portion with solid calcareous matter. Some peculiarities of the shells of the other class of bivalves, the *brachiopoda* (by some recent authors placed among the articulates), are given under that head. These valves are distinguished as dorsal and ventral, instead of right and left. The ventral is commonly the larger one, and is surmounted by a prominent perforated beak, through which the organ passes by which it is attached to foreign bodies. This valve resembles in shape the antique lamps, and the hole in the beak corresponds to that for the wick; they are hence known as lamp shells.—The class *cephalopoda* includes many genera whose shells are concealed within the soft parts. Many of these are known only as fossils, and nothing is left to indicate their former existence but the numerous stony pointed bodies and pens, which were at the same time the skeleton and partial receptacle of the soft portion of the animal. One of these calamary or squid-like fossils, *belemno-*

teuthis, found in the Oxford clay at Chippenham, England, was so perfectly preserved that the muscular mantle, fins, ink bag, funnel, eyes, and tentacles with their horny hooks, were all distinguishable. A similar discovery, described by Buckland, is noticed in the article BELEMNITE. Some of the fossil ink bags found in the lias are nearly a foot in length, and are invested with a brilliant pearly layer; the ink forms excellent sepia. In the *sepiadæ* of this class the shell is the spongy calcareous substance known as cuttle bone. It is a broad laminated plate, as long and wide as the body in which it is enclosed. It grows to an extraordinary size, one being noticed by Banks and Solander in the Pacific, near the equator, which was about 6 ft. in length. To the same class belongs the *nautilus pompilius*, the only living representative of the order *tetrabranchiata*, of which fully 1,400 fossil species are known, among which are the ammonites. Its light shell is separated into air chambers by numerous partitions, which greatly increase its strength and add but little to its weight. The four species of argonauts are also cephalopods; their shell is thin and translucent like paper, and serves as a boat to the animal that sits unattached within, his long tentacles stretching forth from the projected head, and the short funnel beneath it forcibly spurting forth water, the recoil of which sends the animal backward. This is the shell which Aristotle called the nautilus, and fancifully described, as many others have since, under the name of paper nautilus, as floating in fine weather upon the surface with its sails spread to the breeze.—The whole number of species of molluscous animals known is estimated at about 12,000 recent and 15,000 fossil. Many of the living species furnish wholesome food, and some are esteemed as delicacies. The shells are principally composed of carbonate of lime, the other ingredients, of the oyster for instance, being 1·2 per cent. of phosphate of lime, and 0·5 of animal matter; the shells of the brachiopods consist largely of phosphate of lime. They are therefore well adapted for being burnt to quicklime, used as calcareous fluxes in smelting ores, or applied as fertilizers to the soil. The marine shells, by the immense numbers in which they are produced, perform an important office in abstracting from the sea water its excess of calcareous matter, and thus aiding to maintain its purity. As objects of beauty, shells have always been admired, and frequently appropriated to uses as ornaments. Some varieties were used by the Athenians as ballots, with the name upon them of the person to be banished, whence the term ostracism. Some shells, as the *cypræa moneta*, have served the purposes of coin among rude nations. Others, as the marine *avicula margaritifera* and the fresh-water *unio margaritiferus*, are noted for the pearls which are secreted between their valves around some foreign substance. Mother-of-pearl is the polished shell of nacreous structure. Rare species of shells are highly prized by collectors, and single specimens have been sold for exorbitant sums. Woodward ("Manual of the Mollusca") cites the sums once paid for such, as 100 guineas for a *carinaria*, now worth only 1*s.*; 40 for a wentletrap, now worth 5*s.* The *conus gloria maris* has fetched £50 more than once, and *cypræa umbilicata* sold for £30 in 1850.

CONCHOS, or **Conchas,** a river of Chihuahua, Mexico, which rises high up in the Sierra Madre, flows S. E., N. E., and then N., through a beautiful tract of country, comprising the richest of the table land of Chihuahua, and empties into the Rio Grande near Presidio del Norte, in lat. 29° 30′ N., lon. 104° 40′ W., after a course of about 350 m. It is the largest tributary of the Rio Grande, and very little inferior in size to that river itself. Its principal branches are the Florido, Buenavista, San Pedro, Chihuahua, and Balleza.



CONCINI, Concino. See ANCRE, MARSHAL D'.

CONCLAVE (Lat. *cum*, with, and *clavis*, key), the apartments where the cardinals of the Roman Catholic church assemble for the election of a new pope, or the assembly of cardinals shut up for such election. Many reasons have led to the bestowing on the college of cardinals the exclusive right of electing the pope, as well as to the reclusion in which they are kept while exercising that right. During the era of persecution the position of bishop in Rome or elsewhere was one of great peril, for which none but the most eminent in virtue were likely to be chosen by the clergy and people. But already in the age of Constantine the play of human passions became frequently but too apparent both in the men who aspired to the episcopal office, and in those in whose gift it was. In proportion as the church increased in numbers, wealth, spiritual influence, and political power, so did the choice of men to fill such great sees as those of Rome, Constantinople, and others, become the occasion of most unseemly intrigue and strife. The emperors, from motives of policy, wished to have seated in the papal chair men who would subserve their own interests; and from first protecting the liberty of ecclesiastical elections, they soon came to oppress it. Justinian claimed the right of confirming the choice of the Roman clergy and people, and this in practice meant the setting it aside. It was further maintained that Adrian I. had bestowed on Charlemagne the right of choosing the pope; but be that as it may, the German emperors constantly interfered in papal elections, causing thereby ever-recurring disorders, delays, divisions, and sometimes bloodshed. To protect the freedom of the electors, and to put a stop to these scandalous contentions, Nicholas II. in 1059 decreed that in future the election of the Roman pontiff and the administration of his see during the vacancy should be the exclusive right of the cardinals of the Roman church. After a violent struggle with the imperial power, these statutory dispositions triumphed through the energy

of Gregory VII. In 1179 Alexander III. solemnly confirmed the decree of Nicholas, prescribing that a two-thirds vote should be necessary for a valid choice. Meanwhile no statute existed compelling the cardinals to reclusion while discharging their office of electors; but several instances are on record where such reclusion was resorted to with the most beneficial result. The election was thus made in perfect freedom from all outside violence and intrigue. Honorius III. was elected two days after the death of his predecessor, in consequence of the strict reclusion to which the cardinals submitted; while Gregory X. was only chosen after a vacancy of two years and nine months, because the electors were not shut up. These two extreme cases induced Gregory in 1274, during the council of Lyons, to decree a strict reclusion thenceforward, with all the other conditions which have substantially continued down to the present day. After Gregory's death these statutes were repeatedly violated, until the evil thence resulting culminated at the death of Nicholas IV. in 1292, when Celestine V. was chosen after an interregnum of two years and three months. Celestine renewed before his abdication, with increased solemnity and rigor, the pontifical constitutions on the conclave, and had the satisfaction of seeing them carried out to the letter in the conclave which elected Boniface VIII. Boniface, in his turn, confirmed the constitution of Celestine by one of his own, and both were embodied by him in the 6th book of his Decretals. During the council of Trent this reclusion, which had become the uniform law of the church, was again the subject of the most severe and minute legislation by Pius IV. He regulated everything pertaining to the lodging of the cardinals in conclave, to their seclusion from all intercourse with the world outside, their diet, attendants, and the manner of voting. Gregory XV. in 1621 decreed strict reclusion as an absolute condition for validity. Clement XII. in 1732 renewed and confirmed these disciplinary statutes, adding some new rules concerning the administration of the Roman see during its vacancy.—The whole ceremonial observed in the conclave may be thus briefly described from Patricius (Patrizzi) and modern authorities. Nine whole days are given to devotional exercises for the eternal repose of the deceased pontiff. On the ninth take place his obsequies, and on the tenth the cardinals assemble in the Sistine chapel, where a mass in honor of the Holy Ghost is celebrated by the cardinal dean. This over, the cardinal dean intones the *Veni, Creator Spiritus*, and the sacred college, with their officers and attendants, go in procession to that part of the Vatican set apart for their reclusion, immediately adjoining and including both the Sistine and Pauline chapels, with three courts and the surrounding apartments. On their arrival in the Pauline chapel, the cardinal dean chants before the altar the prayer *Deus, qui corda fidelium*, and the papal constitutions on conclaves are read, all present swearing solemnly to observe them. Formerly it was the custom to begin from that moment the rigorous reclusion prescribed by the pontifical decrees. In modern times it only commences on the evening of the tenth day. As soon, however, as the signal for the prescribed reclusion is given, all meet in the chapel, cardinals and conclavists (all the authorized officers and attendants in the conclave), the oath of fidelity and secrecy is administered to conclavists and guardians, and three cardinals (chosen one from each of the three orders of bishops, priests, and deacons), accompanied by the high chamberlain (*camerlingo*) and the first master of ceremonies, make a scrupulous examination of every room and corner from cellar to garret, in order to see that there are no intruders. The only door of communication having been then closed with two strong locks on the outside and two within, the conclave is formally begun. The cells in which the electors are locked up are simple in their construction and their furniture. They are draped in purple for the cardinals created by the last pope, and in green for all the others. The following daily routine is observed as long as the reclusion lasts. At 6 o'clock in the morning a master of ceremonies knocks at the door of each cell to warn the inmate to proceed to the chapel. At 7 the mass of the Holy Ghost is celebrated, after which all except the cardinals withdraw. The cardinals recite the penitential psalms and the litany of the saints, and a first vote is cast. This over, the fathers retire to their cells, breakfast, and take a short walk in the open air. At 2 o'clock P. M. they again meet in the chapel for a second ballot, after which they dine, walk out if they choose, or retire to their respective cells, where a religious silence is observed after dark. Gregory XV. decreed that the cardinals in conclave should vote by secret ballot. Papers of uniform size, texture, and color are distributed to the cardinals; they are folded in such a manner that the part on which each elector writes his own name cannot be opened, while that on which he inscribes the name of his candidate can. The ticket is then folded, closed with sealing-wax, and stamped with the common seal of the conclave. The elector, then kneeling, takes the solemn oath prescribed, and deposits his vote in a chalice placed on the altar. The votes of such as are detained by sickness in their cells are taken with every necessary precaution and formality. When all have voted, three cardinals, chosen one from each order in the sacred college, take the papers one by one from the chalice, read them aloud, and register them, each in succession. As soon as a two-thirds vote is obtained, the fact is announced. The elect, if he accepts, immediately chooses the name by which he is to be known, and receives the first homage of all present. He is next clad in the vestments and insignia of his office, and receives homage

a second time. Thereupon the first in the order of cardinal deacons, preceded by a cross-bearer, goes to a balcony in the Vatican and proclaims the name of the new pope.

CONCORD, a city and the capital of New Hampshire, and the shire town of Merrimack county, situated on the Merrimack river, about 45 m. from the Atlantic coast, and 60 m. N. N. W. of Boston. The Merrimack divides the city N. and S., and the Contoocook winds along the W. half of the N. border. At their confluence is a small island, famous as the place where Mrs. Hannah Dustin and her nurse, Mary Neff, with the aid of a boy, in 1697 killed ten Indians who had taken them captive from Haverhill, Mass. The main part of the city is situated on the W. side of the Merrimack, and is well laid out. The streets are shaded with elms and maples. Fisherville, a village near the junction of the two rivers, lies chiefly in Concord. Millville, a small village 2 m. S. W. of the state house, is the seat of a school for boys. The Merrimack is bordered by wide intervales, which are overflowed by freshets. Four railroads centre in the city, viz.: the Concord, connecting with Nashua, Lowell, and Boston; the Concord and Claremont; the Northern, connecting with Lebanon; and the Boston, Concord, and Montreal, with Plymouth and Haverhill. The population at decennial periods has been as follows: in 1810, 2,398; 1820, 2,838; 1830, 3,702; 1840, 4,903; 1850, 8,584; 1860, 10,896; 1870, 12,241. The state house was erected in 1816, costing $80,000, and rebuilt and enlarged in 1866, at a cost of $175,000. It is of granite, hammered by the convicts in the state prison, which is located in the city. It stands in a beautiful park ornamented with shade trees. The centre of the building is 50 ft. front by 57 deep; the wings are each 38 ft. front by 49 deep; the whole making a parallelogram 126 ft. in length by 49 in width, with the addition of a projection of 4 ft. in the centre of each front. The state asylum for the insane stands on an eminence about half a mile S. W. of the state house. The buildings are of brick, and are well adapted to the purpose. A large farm is connected with the institution, and a considerable portion of the provisions needed for the inmates is produced by the labor of those able to work in the field. There are usually from 225 to 250 inmates. The city hall is a large brick building. Water works, costing about $200,000, were constructed in 1872, and the city is now supplied with pure water from Long pond, 4 m. from the state house, and 120 ft. above Main street. Extensive quarries of beautiful white fine-grained granite exist on the line of the Concord and Claremont railroad, within the city limits. Large quantities, cut and uncut, are shipped to Boston, and thence are exported to southern ports for building purposes. Great water power might be furnished at Sewall's falls, in the Merrimack, 2 m. above the business centre, and at Garvin's falls, 2 m. below. At Fisherville there is also great motive power, partially improved by manufactories erected in Concord and the adjoining town of Boscawen. The city is especially noted for its manufacture of carriages, which are largely exported. There are 120 manufactories of various kinds, employing steam engines having 720 horse power, and water wheels with 734 horse power; capital, about $2,000,000; number of males employed, 1,800, and of females, 350; wages annually paid, $1,000,000; value of products, $3,616,000. The value of the most important articles produced in 1870 was: carriages, $550,000; cotton goods, $250,000; woollen goods, $230,000; leather and leather belting, $300,000; foundery products, $250,000; granite, quarried and dressed, $350,000; furniture, $350,000; reed organs and melodeons, $60,000; harness, $150,000; lumber, $90,000; boots and shoes, $100,000; clothing, $150,000; marble, worked, $60,000; products of railway repair and car shops, $300,000; of printing and bookbinding establishments, $150,000; of silversmithing establishments, $75,000. There are also manufactories of sashes, doors, and blinds, of silver-plated ware, of steel carriage springs, &c. Concord is an important centre of trade, possessing two banks, with an aggregate capital of $350,000, and about 250 stores, with a stock

State House, Concord.

in trade valued at over $800,000. The total valuation of the city is upward of $11,000,000. The public schools in 1872 numbered 25, including a high school, with 30 teachers and 1,295 pupils. The public library contains 6,223 volumes, the state library 11,000, and that of the New Hampshire historical society 6,500. There are two daily and three weekly newspapers, and 16 churches.—Concord was originally the seat of the Penacooks, a powerful tribe of Indians. Passaconaway, a sagamore and a friend of the English, resided here. It was settled in 1725, incorporated under the name of Rumford in 1733, and under its present name in 1765, and made a city in 1853.

CONCORD, a town of Middlesex co., Massachusetts, 18 m. N. W. of Boston by the old county road, and 20 m. by the Fitchburg railroad; pop. in 1870, 2,412. The Indian name of the place was Musketaquid, signifying grass ground. It was settled in 1635, and the name Concord is said to have been given it "from the Christian union and concord among the first company." The first inland settlement made in the Massachusetts colony, it was one of the scenes of the labors of the apostle Eliot. In the Indian wars it bore a prominent part, and in 1669 established a military company, which existed down to a recent period. It had considerable part in King Philip's war, 1675–'6. When the people of Boston overthrew Sir Edmund Andros, a company marched to their aid from Concord. To the French and Indian wars that followed the English revolution Concord contributed many men. As early as 1767 the people of Concord made themselves conspicuous for their opposition to the measures of the British government. The first county convention, that of Middlesex, was held at Concord, Aug. 30 and 31, 1774, and consisted of 150 delegates, every town being represented. This convention adopted resolutions that amounted to a declaration of separation, the last recommending the assembling of a provincial congress; they were signed by 146 members. In September some of the people took part in the expedition to Cambridge, whither a British force had been sent. The judges were not allowed to hold court in the town under the new government. Tories were arrested and "humbled." Military companies were formed, and arms and ammunition purchased. The provincial congress of Massachusetts met at Concord Oct. 11, John Hancock presiding. In February, 1775, the colonial government provided for the accumulation of valuable stores for military uses at Concord, under charge of Col. James Barrett of the town. The village had become a place of arms, and this determined the course of events. British spies visited the place, and an expedition from Boston to seize or destroy the stores was resolved upon by Gen. Gage. The provincial congress met at Concord the second time March 22, 1775, and sat till April 15. On the night of April 18 a detachment of 800 men marched from Boston upon Concord (see Lexington), which place they reached at 7½ o'clock on the morning of the 19th. The country had been thoroughly alarmed; the people were employed in removing and secreting the stores, and the military assembled to the number of 180. When the enemy came in sight, some were for resisting them; but as it was thought proper to throw the entire responsibility upon the invaders, this advice was not followed, and the militia fell slowly back, and took post upon the side of a hill to the right. They were at first under the command of Major John Buttrick; but Col. Barrett, his superior, soon arrived on the ground, and ordered the men to cross the North bridge, which was done. The British now had possession of a large part of the town, and while some of them were engaged in destroying arms and provisions, detachments were sent to secure the South and North bridges. A part of those sent to the North bridge went on to Col. Barrett's residence, where they were engaged in the work of search and destruction, when they were interrupted by the attack that was made on their comrades at the bridge. The Americans who had retreated over the North bridge were drawn up not far from it, and were joined by others from several neighboring towns. As it was believed the enemy were burning the village, the resolution was taken to attack them, and by Col. Barrett's command the militia and "minutemen" marched toward the bridge; some of the Acton minutemen took the head of the column, but stood abreast with the Concord minutemen when they halted at the W. end of the bridge. The British drew up on the E. bank, and began to pull up the planks of the bridge. Major Buttrick called to them to desist, and ordered his men to increase their pace. The British desisted, but fired several muskets, as signals, it was supposed; but when the Americans were 10 or 15 rods from the river, a single gun was discharged at them, the ball from which wounded Luther Blanchard, an Acton fifer, and Jonas Brown, a Concord soldier. Immediately a volley was fired, by which Capt. Davis and Abner Hosmer of Acton were slain. Major Buttrick then gave the order to fire, discharging his own gun instantly. The order was promptly obeyed, and a general fusillade ensued from both sides. The British lost several men, two being killed, when they retreated, meeting reënforcements as they marched to the centre of the town. The Americans followed, and took post on the side of the road by which they would have to return to Boston. The companies at Col. Barrett's were interrupted in their operations by the firing at the bridge, and returned to the village without molestation. Those at the South bridge did the same. Meantime, the British had been engaged in acts of violence in the village, directed principally against military articles, such as throwing balls into wells,

&c. The only building fired was the court house, which was not much damaged. Some indignities were offered to individuals, and there was a little pillaging. About noon the retreat commenced, and the enemy were followed along the road to Lexington by the provincials, who inflicted much injury upon them. Concord had five men wounded in the action. So far as the deliberate purpose of the Americans was concerned, the revolution was begun by the determination of the militia officers to march upon the North bridge; and the first order to fire upon the royal troops came from Major Buttrick. In 1835 a granite obelisk, 28 ft. high, including the base, which is 5½ ft. broad, was erected on the spot where the first British soldiers fell, with a suitable inscription. The grave in which two British soldiers were buried, supposed to have been the first who fell in the war, is near the monument. The spot is one of great rural beauty. The road along which the troops marched has been many years closed, and the bridge over which the first volleys of the revolution were exchanged has long since disappeared. During the war Concord contributed largely of men and money to the common cause, and sent great quantities of fuel, hay, provisions, and clothing to the army. Though the population was but 1,300, it had 174 men in the army of 1775; and at later periods of the war its conduct was equally spirited. The money to pay the soldiers was raised by the town. Harvard college was removed to Concord in 1775, when the college buildings at Cambridge were occupied by a portion of the American army then besieging Boston. It returned to Cambridge in June, 1776.—Concord is distinguished by its quiet beauty. The sluggish character of Concord river, which falls into the Merrimack at Lowell, 15 m. distant, after a total course of about 40 m., has prevented it from being turned to manufacturing purposes, and its natural beauties have been preserved. There are, however, a cotton mill and a pail and tub factory. There are good schools, two or three churches, a bank, and an insurance company. The Assabet, which falls into the Concord, not far from the scene of the battle, is a stream of singular beauty, and both have been made familiar to the world by the writings of Thoreau and Hawthorne. The quiet and repose of the place have made it a favorite with men of letters. Ralph Waldo Emerson, grandson of the Rev. William Emerson, who was pastor there in the revolution, and an eminent patriot, resides there; and Hawthorne and Thoreau were also residents of the village. The "Mosses from an Old Manse," one of Hawthorne's finest works, takes its name from the fact that it was partially written, and entirely arranged, in the parsonage house of the Rev. Dr. Ezra Ripley, who was pastor at Concord from 1778 to 1842. A public library building, presented to the town by Mr. W. C. Munroe, was opened Oct. 1, 1873, the library containing 10,267 volumes.

CONCORDANCE, a book which contains all or the principal words that occur in the Bible, arranged in alphabetical order, with references to the book, chapter, and verse in which each occurs, designed to assist the inquirer to find any passage of Scripture of which he may remember one or more words. Concordances of the Hebrew and Greek texts have been made, and of the principal modern translations. The earliest concordances were of the Latin Vulgate, in the 13th century, the first being that of Antonius of Padua, and the second that of Cardinal Hugo de St. Cher. Euthalius of Rhodes made one of the Greek text about the year 1300, which was however lost; and the task was performed again for the New Testament, in the middle of the 16th century, by Betuleius, and for the Septuagint, at the beginning of the 17th, by Konrad Kircher. The latter work was improved by Trommius about 1690, and the former by Henry Stephens about 1600, and still further by Schmidt in 1638. The most recent Greek concordance is that of Bruder (Leipsic, 1843). The first Hebrew concordance was completed by Rabbi Isaac ben Calonymos Nathan about 1438, was printed at Venice in 1523, and again in 1564, and has been improved by Calasio (Rome, 1621), Buxtorf (Basel, 1632), and Fürst (Leipsic, 1837 *et seq.*). All the concordances, except the Hebrew, prior to the editions of the Bible by Robert Stephens (about 1550), which first contained the Greek and Latin texts divided into verses, made references only to chapters, and then indicated whether the passage was near the beginning, middle, or end of the chapter, by the letters *a*, *b*, *c*, &c. The first English concordance was of the New Testament, by Thomas Gybson, prior to 1540. The earliest English concordance of the entire Bible is that of Marbeck (1550). Cruden's "Complete Concordance" (1737, and often since) is the basis of every English concordance since published. The best edition is that of the society for the promotion of Christian knowledge (London, 1859). This, however, is far from complete, many important words being wholly omitted. An "Exhaustive Concordance," by James Strong, is announced (1873) as nearly ready for publication. In "The Englishman's Hebrew Concordance" (London, 1843), and "The Englishman's Greek Concordance" (London and New York, 1848), the words in the original tongues are given in their alphabetical order, but the passages are quoted from the English version.—Similar alphabetical vocabularies of other books than the Bible are termed concordances, as the concordance to Shakespeare, by Mary Cowden Clarke.

CONCORDAT, a treaty or agreement entered into by the see of Rome with a secular prince or government, touching one or more points of ecclesiastical discipline. The Roman Catholic church is governed by her own laws and observances in all matters not definitely settled by Christ or his apostles. (See CANON LAW.)

Concordats are simply the arrangement by treaty of such laws and observances as lie outside the verge of divine law; the ecclesiastical power whereby similar laws and observances were established moulding and modifying them to meet the varying mutations of human affairs, and the different requirements of time and place. The name was probably first used in 1418, being applied to the stipulations entered into by Martin V. on the one side, and England, Germany, and France on the other. The most notable concordat of modern times was that between Pius VII. and Bonaparte in 1801, by which the Christian religion, which had been formally abolished by the revolutionary leaders, was reëstablished in France. Late instances of concordats are those made with Austria in 1855, Würtemberg in 1857, and Portugal in 1859.

CONCORDIA, an E. central parish of Louisiana, bounded E. by the Mississippi river, W. by the Tensas and Washita, and S. by Red river; area, 790 sq. m.; pop. in 1870, 9,977, of whom 9,257 were colored. Its surface is low, and inundations are consequently of frequent occurrence. There are many lakes and sloughs which occupy a considerable portion of the parish. The greater part of the land available for agriculture is laid out in cotton plantations. The chief productions in 1870 were 62,950 bushels of Indian corn, 4,350 of sweet potatoes, and 26,712 bales of cotton. There were 1,035 horses, 2,280 mules, 1,079 milch cows, 2,490 other cattle, and 4,017 swine. Capital, Vidalia.

CONCORDIA, a divinity of peace, in whose honor several temples were erected in Rome. The most ancient and celebrated of these temples was that built by Camillus, shortly before his death, on the declivity of the capitol, to commemorate the reconciliation of the patri-

Concordia. (Roman Medal, Zell's Pantheon.)

cians and plebeians, after the enactment of the Licinian rogations. Concordia was generally represented as a matron holding in her right hand a patera or an olive branch, and in her left hand a cornucopia. Her symbols were two hands clasped together, and two serpents entwined about a wand.

CONCORDIÆ FORMULA, the seventh and last symbolical book of the Lutheran church, in which the doctrinal development of that church in respect to the Lord's supper and the person of Christ was completed. The elector Augustus of Saxony, a partisan of Lutheran orthodoxy, made the sixth attempt to reconcile the stricter Lutherans, the milder Philippists, and the crypto-Calvinists to a common confession, when in 1576 he summoned the Lutheran theologians to meet for counsel in a convent at Torgau. The result of their deliberations, known as the "Torgau book," was submitted to the various German Lutheran churches, most of which, however, returned replies and criticisms instead of an unconditional assent. The elector therefore convened on March 11, 1577, in the cloister of Bergen, near Magdeburg, the three eminent theologians, Andreæ, Chemnitz, and Selnecker, to revise the Torgau book. In their first session they prepared the *Epitome* and the *Solida Declaratio*, which were elaborated anew in April, and received their final form in a third session in May, to which Musculus, Cornerus, and Chytræus were also admitted. These two statements of faith, of which the latter is the fuller, constitute the "Form of Concord." It was at once accepted by 3 electors (2 of whom soon seceded), 20 dukes and margraves, 24 counts, and 35 free cities, and was rejected by Hesse, Nassau, Pomerania, Holstein, Anhalt, and many important free cities. It was originally drawn up in German, and was translated into Latin successively by Osiander, Selnecker, and the convention of Quedlinburg in 1583; the last of which only was approved by the elector, and received as authentic. A complete history of the "Form of Concord" was written by J. N. Anton (Leipsic, 1779).

CONCRETE (Lat. *concrescere*, to grow together), a name given by architects and engineers to a mixture of common lime, hydraulic lime, or hydraulic cement, with sand and gravel or broken stones. A mixture of sand and hydraulic lime is also called concrete. It is used in the construction of the foundations and walls of buildings, of fortifications and of piers in harbors or in the sea, of aqueducts, sewers, and other structures much exposed to the action of the elements, or subjected to great pressure, being well adapted to these purposes in consequence of the hardness and insolubility it attains in solidifying. Formerly the name concrete was only applied when common lime was used, but that kind of concrete is now rarely made (except under extraordinary circumstances and by a newly applied process which will be noticed at the end of this article) when hydraulic lime or cement can be conveniently obtained. In the preparation of concrete with common lime, the London architects formerly employed one part of rich lime to six parts of unscreened Thames ballast, which usually consists of six parts of coarse pebbles to one of sand. The rule is that the slaked

lime should a little more than fill the voids in the pebbles and sand. Béton, or concrete made with hydraulic lime or cement, was employed in ancient times in some of the most renowned works of history. The factitious stones used by the Babylonians, Egyptians, and Phœnicians, as well as by the Greeks and Romans, were all a species of béton, or what is now called concrete. The Romans used it in large quantities in the construction of harbors and piers in the Mediterranean, and for aqueducts and roads, many portions of which exist at the present day. Their matrix was made of pozzuolana or trass, mixed with fat lime. The best modern concrete is made by using Portland cement, but a good article is also made with Teil lime and other hydraulic limes. An important quality that should be possessed by a lime or cement is that of setting slowly, to secure its more perfect crystallization and a firmer binding of the gravelly material. It is also desirable as allowing any portions of the material which may not have been perfectly slaked to expand in the process without rupturing the partially hardened structure; and this shows the importance of having the matrix well slaked and thoroughly incorporated before hardening begins.—Our advanced knowledge of the preparation of concrete is much owing to the experiments of M. François Coignet of Paris, whose manufacture of *béton aggloméré* has a world-wide celebrity. In this process, the matrix or paste is first prepared by mixing about three parts of hydraulic lime or cement with one part of water, and thoroughly triturating it in a mill until it is brought to a peculiar state of sticky consistency, which is best known by experience. Clean, sharp sand is then added in the proportion of about two parts to one of lime or cement, or one and a half to one of the paste. This is then well ground in a powerful mill and incorporated with an equal bulk, or a little more, of broken stone or coarse gravel. This may be formed into blocks of any required size, or the whole structure to be erected may be formed as a monolith. In either case, mechanical compaction is an important part of the process, and is effected by ramming the mixture with iron rammers weighing from 10 to 20 lbs. Blocks are made in moulds whose parts are separable. Layer after layer is thrown in and well condensed by ramming, and that this may be effected is one of the reasons why the amount of water should be carefully proportioned. The moulds are taken off in sections, and therefore may be of almost any shape, so that figures and traceries of any desired form may be copied. The blocks are then left exposed to the air and weather for several weeks or months, sometimes receiving occasional sprinklings of water. In time they become as impervious to water as many natural stones, and capable of resisting the influences of frost in the open air, or the action of sea water. When monolithic walls are made, a form is used open at the top and bottom, in which the concrete is rammed till it is filled, when it is raised as successive layers are added. In this way many fine structures have been erected, particularly in France. Of the Vanne aqueduct for supplying water to Paris, 37 m. have been executed in béton aggloméré. In the forest of Fontainebleau there are about 3 m. of arches, some of which are 50 ft. high. The whole structure, including arches and pipe, is one mass of solid masonry, without joints. A Gothic church at Vezinet, near Paris, having a spire 130 ft. high, is also a monolith of concrete, and exhibits, it is said, every evidence of durability. The lighthouse at Port Said, the northern terminus of the Suez canal, is also built of béton of Teil lime and Port Said sand, and is a monolith 180 ft. high. The jetties which form the harbor at Port Said are built of huge blocks of concrete formed of the same material. In their construction about 120,000 tons of Teil hydraulic lime were used. There were 25,000 blocks, each weighing 25 tons. The proportions were: lime in powder, 548 lbs.; desert sand, one cubic yard, mixed with sea water and poured into moulds, and hardened by exposure to the air for two or three months. M. Pascal, the chief engineer in the construction of docks at Marseilles, made a mortar in the proportion of Teil lime three parts, sand five parts, which was formed into a concrete by adding to one volume of mortar two volumes of broken stone.—One of the most extensive applications of hydraulic concrete in modern times was made by the French in their works at the harbor of Algiers, commencing in 1831. The mole which shelters the harbor is so exposed to winds that breaches were constantly being made in it by the force of the sea, and to such an extent that in former times the Moors were compelled to keep employed a large number of workmen to repair it, at an annual expense of more than $60,000. When the French commenced the reconstruction of the mole in 1833, after the failure of partial repairs, the first operation was to raise an outer embankment of large stones, under whose cover the foundation might be partially restored. It was intended to form this embankment of *pierre perdue*, and to employ natural stones of 100 to 140 cubic feet, and 212,000 cubic feet were thus used at a great expense; but during the next winter the embankment was completely destroyed by the waves, one block of 141 cubic feet having been carried completely across the mouth of the harbor. It thus became necessary to rebuild the entire embankment of blocks so large that no action of the sea could move them. Under the circumstances it was found that the required size would be about 353 cubic feet. The expense of quarrying and transporting such enormous blocks of stone led to the employment of artificial stone, or béton. Two kinds of blocks were manufactured; the first

in the water in the place they were intended to occupy, and the second on shore, to be afterward thrown into the sea. The first were made by immersing béton in caissons which were constructed of timber and plank, and lined on the inside with tarred cloth, the four sides being connected by hinged angle irons so as to be readily unshipped. The second kind of blocks were prepared on shore in moulds of timber and plank, resting upon an inclined plane, ending at the point where the block was to be sunk. After the béton had properly set, the sides were removed and the block launched into the sea. In making the mortar for the first description of blocks, one part of rich lime was slaked and made into a paste and then mixed with two parts of Italian pozzuolana, while for the blocks made on shore pozzuolana was mixed with an equal quantity of sand. The lime employed was from a hard, granular limestone, weighing about 156 lbs. per cubic foot. Slaked and reduced to the consistence of a thick pulp, it was found to absorb once and a half its weight of water and to increase in bulk 75 per cent. One volume of this with two volumes of pozzuolana made two volumes of mortar. To form the concrete, one part of mortar was incorporated with two parts of broken stone of about 1½ cubic feet. The entire work was performed in five years at a cost of less than $420,000, notwithstanding that the mole at the time of the occupation of Algiers by the French army in 1830 was in a state of complete dilapidation, in spite of the extensive repairs which had been annually made by the Moors for two centuries. The success met with in this work established two important facts: 1, that blocks of béton can be made sufficiently strong to resist the action of the heaviest waves, and form indestructible masses; 2, that these blocks are immovable by the waves when constructed above a certain size, determined by experiment to be about 353 cubic feet. One great advantage in the use of blocks of concrete over those of stone is in the diminished cost of handling and transportation, because the concrete blocks can be made at the place where they are used. The béton used by Vicat for the bridge of Souillac, upon the Dordogne, was composed of 26 parts of hydraulic lime in paste, 39 of granitic sand, and 66 of gravel. It was found to diminish in volume in the proportion of 1·31 to 1.—The immense masses of concrete which form the foundations of the East River bridge between New York and Brooklyn are composed of one part of Rosendale cement, two of sand, and four of coarse beach gravel from an inch to 2½ inches in diameter. The cement and sand were first mixed with water in a mill, and afterward incorporated with the gravel by means of shovels used by hand, the latter operation being performed for the most in the caissons, which were 172 ft. in length by 102 ft. in width. As this concrete lies below the bed of the river, and is therefore confined, there is little doubt that it will endure for centuries. The concrete blocks which form the foundation of the piers that are now (June, 1873) under construction at the Battery in New York harbor, are composed of one part of Portland cement, two of sand, and five of broken trap rock from the Palisades on the Hudson. The matrix of cement and sand was first formed by hand, and afterward incorporated with the broken stone by the same process. It was then shovelled into forms and compressed by ramming. After the béton had set, the forms were removed, and the blocks were exposed to the weather for two months. The concrete with which the natural stone masonry above the water floor is filled in is mixed in the same way, and rammed down in the spaces left by the walls and arches. Concrete is used as a foundation for roads and for cement walks in parks. A good article for this purpose may be made by using equal parts of Rosendale and Portland cements with sand and broken stone.—The artificial stone of Mr. Frederick Ransome, patented in 1856, made by the patent concrete stone company at East Greenwich, near London, England, is one of the remarkable productions of the day, not only furnishing an excellent building stone, but also a material for making a superior quality of grindstones. This concrete is composed of sand held together by silicate of lime, and is formed by an indirect process in which silicate of soda is decomposed by chloride of calcium. The silicate of soda is made by digesting flints with a solution of caustic soda of about 1·2 sp. gr. in boilers, under a pressure of 70 or 80 lbs. to the square inch. The solution of silicate of soda which results should have a specific gravity of about 1·7. Clean sharp sand, which has been dried in a current of hot air, is then mingled with a little finely ground chalk or marble, and the silicate of soda is added in the proportion of a gallon to the bushel of mixture, and the whole is thoroughly triturated in a mill. It becomes pasty during the operation, and susceptible of being moulded into any desired form. The mould blocks, formed by ramming, are then nearly saturated with a solution of chloride of calcium of about 1·4 sp. gr. Double decomposition immediately takes place, whereby silicate of lime and chloride of sodium, or common salt, are produced; and in a few minutes the blocks become hard enough to be handled. They are then immersed in vats containing the solution of chloride of calcium at a temperature of about 212° F., in order that a thorough decomposition of the silicate of soda and formation of silicate of lime may be effected. The latter substance, being insoluble and firmly enveloping the grains of sand, forms a firm and it is believed durable block of stone. The chloride of sodium, being soluble, is then discharged by displacement with water. It might be supposed that the stone would be left in a very porous condition, but experiment has proved that this is not the

case. Dr. Charles T. Jackson of Boston, after exhausting the air from the stone by means of a vacuum, found that it would absorb only about 16 per cent. of moisture. Under ordinary circumstances it may be considered as practically impervious to water, and is found to be quite as firm as most sandstones. Prof. Ansted of King's college, London, found that it would resist a crushing force of 4,200 lbs. to the square inch, and that its tensile strength was equal to 360 lbs. to the square inch; while natural Portland limestone, Bath stone, and Caen stones possessed respectively only 201, 145, and 140 lbs. tensile strength to the square inch. It is said that the best material that has yet been found for grindstones is that made by this process. The grains of sharp sand are held so firmly by the matrix of silicate of lime that they are capable of being made to cut away iron or steel with great rapidity. Experiments made by the Messrs. Donkin of Bermondsey showed that, compared with the best Newcastle stone, the Ransome stone had a capacity of cutting away steel in the proportion of 50 to 1. The artificial stone possesses the advantage, for large grindstones, of having more uniformity of structure than can be found in large blocks of natural stone, and it can be more readily formed into grindstones of various sizes. —The American building block company produce an artificial stone with silicious sand and lime, by subjecting the mixture to great pressure. There are two processes. The first, that of Foster, is as follows: Rich lime is slaked with a small quantity of water, and mixed with moist sand in sufficient quantity to fill the voids. The mortar is then put in moulds and subjected to great pressure, which increases the tendency to formation of silicate of lime. The pressure should be so great that the grains of sand are forced into almost actual contact, so that when the chemical action is completed nothing but silica, and silicate of lime holding it together, will remain in the block; the surplus of lime compounds being forced to the outside, where, by slowly hardening in the presence of air, they form a coating which does not detract from the value of the stone. Vanderburgh's process employs quick instead of slaked lime, which being mixed with moist sand is slaked by steam under pressure. A more complete union between the lime and sand is thus effected, principally in consequence of the greater degree of heat employed; and it is also found that the stone hardens more rapidly in Vanderburgh's than in Foster's process. The Union stone company of Boston, Mass., produce an artificial stone in imitation of several natural stones, the fabrication of which is founded upon the discovery of M. Sorel, a French chemist, that the double oxide and chloride of magnesium forms an excellent hydraulic cement. The materials used are magnesite (native carbonate of magnesia, which is found in various parts of the United States and Canada), chloride of magnesium, and sand, or powdered marble or other stone. The magnesite, reduced to caustic magnesia by burning, is then mixed with sand or powdered stone in the desired proportions. A solution of chloride of magnesium is added, and the mixture is triturated in a mill, when it is turned into moulds and firmly rammed. Hardening commences immediately, so that the block may be removed as soon as the ramming is done. —In consequence of the great advance in the knowledge of limes and cements that has taken place within the last few years, and the increased attention now being paid to the subject by chemists, engineers, and architects, it is probable that various kinds of artificial stone may in the future be used as materials of construction, in many cases, with considerable advantage.—Full information in regard to the manufacture of concrete may be found in the "Practical Treatise on Coignet Béton and other Artificial Stone," by Brevet Major Gen. Q. A. Gillmore, U. S. A. (New York, 1871); "Report on the Hydraulic Lime of Teil," by Leonard F. Beckwith, C. E. (New York, 1873); and Henry Reid's "Treatise on Concrete" (London, 1869).

CONCUBINAGE (Lat. *concubare*, to cohabit), a term applied in ancient times to a quasi-conjugal relation. Among the Hebrews the concubine was liable to be discarded, and to see her offspring excluded from the inheritance, though in most cases provisions were made for her and her children. The barrenness of a marriage often led to concubinage. Sometimes, with the wife's consent, her housemaid became the husband's concubine, to bring children into the family, but without his ceasing to stand in a marital relation to the wife. Subsequently the laws attempted to check excesses. The faithlessness of a concubine was not punished as severely as that of a wife; yet the line of demarcation between the two was so narrow that the paramour of the concubine was considered as her husband and as the son-in-law of her father. The first act of a usurper consisted generally in appropriating the concubines of his predecessor. Among the Persians concubinage likewise prevailed. Darius was followed to the battle field by numerous concubines, arrayed in regal splendor. Among the ancient Egyptians priests were allowed only one wife; and though polygamy was not prohibited among the rest of the people, monogamy seems to have been the general practice. Among the Greeks the concubine was usually a native-born female, who occupied a position between a wife, a servant, and a harlot. Outrages on her person were resented as severely as if she had been a wife; but she had to perform menial services, and after the death of her quasi-husband she was often treated like a slave. The laws of Athens sanctioned the relation of concubinage, which however was more trifled with among the Greeks than among the Hebrews; and the concubine was often made over to others, especially to guests of the house or to sons.—In Rome

the regular paramour of a married man was originally called *pellex* (harlot). The laws of Numa Pompilius excluded her from legal wedlock, and she was only admitted to the temples after having cut off her hair and sacrificed a lamb. Afterward the designation of concubine superseded that of pellex, and the illicit character of the relation was removed, so far as concerned the permanent cohabitation of a Roman spinster with a bachelor or widower, who was not a blood or collateral relation. No written contract was required by the law, but the social status of the wife was denied to the concubine; and the children, though regarded as of more honorable origin than those of unknown or disgraceful parentage, were yet looked upon as quasi-fatherless. The concubine seems to have been so far considered as a wife as to be liable to punishment for adultery. Concubines usually belonged to the lower classes; and at one time free-born Roman girls were precluded from becoming concubines unless they had sunk to the lowest depth of degradation, or had been employed on the stage or in other pursuits which were then considered disreputable. Subsequently it became requisite for a concubine to be a free-born Roman, and some authorities doubt whether common prostitutes were eligible for the position at any period of Roman history. Cæsar allowed to each Roman as many concubines as he desired. Vespasian, Antoninus Pius, and other widowers who had children by their deceased wives, preferred concubinage to new marriages. Constantine made legal marriage with a concubine indispensable for legitimizing the children; but this regulation had little effect, and he eventually allowed a concubine in addition to a wife. The relation continued to prevail to some extent under Justinian, with the legal designation of *licita consuetudo;* and though suppressed by the emperor Leo I., it was retained for a considerable period.—The church of Rome forbade temporary concubinage; but a lifelong relation of the kind, though not expressly sanctioned, was long tolerated. The council of Toledo, A. D. 400, punished it with excommunication for married men, but bachelors who kept concubines were not excluded from the communion. St. Isidore, archbishop of Seville (died in 636), expressed the opinion that no Christian ought to have more than one wife or one concubine. The term priestess often occurs in mediæval writings to designate the concubine of a priest. Leo X. (1513–'21) and other popes opposed concubinage, and the council of Trent declared it to be criminal. The Protestant churches do not seem to have ever sanctioned the relation in any form.—Among the Germans the relation with a *Nebenweib* or *Halbweib* (half-wife) was prohibited by imperial regulations in 1530, and made liable to penalties in 1577, which however were seldom inflicted, and the case was habitually disposed of by enforcing a separation. For a long time the children of concubines were looked upon as bastards, and were not entitled to inherit the property of the deceased father, which was confiscated by the state. In more recent times this rigor has been greatly relaxed, and the claims on the father granted to the children by the ancient Roman laws are generally conceded to them in Germany, though the practice varies in different states.—In France, as in other countries, the term concubinage was often applied to illicit relations which do not strictly belong to that category; and the children resulting from such alliances, though not regarded as legitimate, were not deprived of rights. There, as in many other parts of the world, whenever they rose to eminence they gloried in the appellation of bastards, and were frequently legitimated by the king. Until the revolution marriages were celebrated only in churches, and parties whose union was not consecrated at the altar were legally regarded as living in concubinage, and the children as bastards. The revocation of the edict of Nantes especially doomed Protestant children to these disabilities.—In regard to China, S. Wells Williams states that it is not infrequent for a man to secure a maid servant in the family, with the consent of his wife, by purchasing her for a concubine; especially if his occupation frequently calls him away from home, in which case he takes her as his travelling companion, and leaves his wife in charge of the household. The sons of a concubine being considered as legally belonging to the wife, parents betroth their daughters early, so as to prevent them from becoming concubines. Among the masses of the people it is rare to find more than one woman to one man; but in about two fifths of the wealthier families there are one or more concubines. The degradation of the wife, the elevation of the concubine, and the taking of a second wife are regarded as illegal and void; and the status of the purchased concubine is as carefully defined by the law as that of the wedded wife. The widow is occasionally sold as a concubine by her father-in-law; but this being regarded as degrading, and depriving her of the custody of her children, widows generally strive to escape from this fate. A widower is not restrained by law from marrying any of his concubines. In Japan concubinage is sanctioned by law, and is not regarded as particularly improper.—As regards Mohammedan and other countries where polygamy prevails, see POLYGAMY.

CONDAMINE, Charles Marie de la, a French geographer, born in Paris, Jan. 28, 1701, died there, Feb. 4, 1774. He was educated at the university of his native city, and in 1719 entered the army, and accompanied his uncle the chevelier de Cources to the siege of Rosas, where he showed that contempt of danger and spirit of enterprise which in after life was exhibited in another field. He soon abandoned the military profession, and joined an expedition which was proceeding to the Mediterranean to explore the coasts of Asia and Africa.

During his absence he visited the Troad, Cyprus, Jerusalem, and Constantinople. In 1735 the academy of sciences sent him with Bouguer and others to Peru, to measure an arc of the meridian, for the purpose of more accurately determining the dimensions and figure of the earth. He returned to France in 1743, and prepared accounts of the voyage, travels, and labors of the commission. His *Relation abrégée d'un voyage fait dans l'intérieur de l'Amérique Méridionale* appeared in 1745, and *La figure de la terre déterminée par les observations de MM. de la Condamine et Bouguer* in 1749. While in South America he made observations on the manufacture of articles of caoutchouc by the natives, and published in 1751 an account of an elastic resin, giving a description of several trees yielding caoutchouc, and to him is ascribed the introduction of the article into Europe. In 1748 he was made a fellow of the royal society of London, and in 1760 a member of the academy of sciences in Paris. He labored to promote in France the practice of inoculation for smallpox which was then followed in England. He left a number of treatises on geography, natural history, and physics, and in his day had some reputation as a writer of verses. The discovery by which he is best known is that the deflection of a plumb line by a mountain is large enough to be measured.

CONDÉ. I. Condé-sur-l'Escaut, a town of France, in the department of Le Nord, near the Belgian frontier, 7 m. N. E. of Valenciennes; pop. in 1866, 4,642. It is noted for its arsenal and fortifications, for its trade in coal, cattle, and corn, and its manufactories of cordage, leather, chiccory, and starch. A canal 15 m. long connects it with Mons in Belgium. It was taken by the Austrians in 1793. The princes of Condé took their title from this place. **II. Condé-sur-Noireau,** a town in the department of Calvados, at the confluence of the Noireau and Drance rivers, 24 m. S. S. W. of Caen; pop. in 1866, 6,643. It was one of the first towns to sympathize with the reformation, became a rallying point of the Protestants at the beginning of the 16th century, and a provincial synod was held there in 1674. Dumont d'Urville, the traveller, was a native of this town.

CONDÉ, the name of a younger branch of the Bourbon family, the successive heads of which have played important parts in French history. **I. Louis I. de Bourbon,** prince de, born at Vendôme, May 7, 1530, died March 13, 1569. The youngest brother of Antoine de Bourbon, king of Navarre, and uncle of Henry IV., he early distinguished himself by his gallantry during the wars against Charles V. and Philip II. of Spain. He adopted the faith of Calvin, like the rest of his family, and became the chief of the Protestant party. The rival of the Guise family, he took a secret part in the conspiracy of Amboise in 1560, and was arrested at Orleans a few weeks later, sentenced to death, and saved only by the accession of Charles IX. to the throne, which put an end to the Guise influence. After the slaughter of Vassy in 1562, he took up arms, was defeated, and taken prisoner at Dreux by François de Guise. Being liberated by the edict of Amboise in 1563, he again revolted, and in 1567 nearly succeeded in overtaking the king and the court at Meaux, but was shortly after defeated at St. Denis, near Paris. He was amnestied by the peace of Longjumeau in 1568; but being aware of the designs of the court against him, he renewed the civil war, fought at Jarnac with undaunted courage, although he had been severely wounded, and was taken prisoner and shot by Montesquiou, an officer of the duke of Anjou. **II. Henri I. de Bourbon,** prince de, son of the preceding, born at Ferté-sous-Jouarre in December, 1552, died at St. Jean d'Angély, March 5, 1588. After the death of his father he joined the Protestant army, then led by Coligni. He escaped the massacre of St. Bartholomew by promising to abjure Protestantism; but eluding his keepers, he fled to Germany, whence he wrote to Henry III. demanding the free exercise of his religion. Collecting a military force, he repaired to the camp of the duke of Alençon, now the leader of the Protestants. In 1585 he was excommunicated by Pope Sixtus V. together with the king of Navarre. He died of poison administered by his servants. His wife, Catherine de la Trémouille, was suspected of having instigated the crime, and proceedings were instituted against her; but Henry IV. threw the papers into the fire, and the parliament of Paris pronounced her innocent. Suspicion has, however, attached to her memory. It has been said that she committed the crime in order to conceal the consequences of an intrigue with a page, according to some, but according to others with Henry IV. himself. **III. Henri II. de Bourbon,** prince de, son of the preceding, born at St. Jean d'Angély, Sept. 1, 1588, died in Paris, in December, 1646. He was born six months after the death of his father, was taken to court at the age of seven years, and brought up a Catholic. In 1609 Henry IV. caused him to be married to Marguerite de Montmorency, with whom he was himself enamored. Condé, perceiving the attentions which the king paid to his wife, fled with her to Brussels; and Henry complained to the Spanish court on account of the favorable reception given to a prince of the blood royal who had left the kingdom without permission. Condé continued his flight to Italy, and did not return to Paris until after the death of Henry. He then joined the malcontents, and, having put forth a fierce manifesto against the government, left the court. He and his adherents were declared guilty of high treason. The treaty of Loudun (1616) between the queen and Condé restored him to his estates; but he continued his intrigues. He was arrested, thrown into the Bastile, and afterward imprisoned at Vincennes,

where he remained three years. He then asked to be set at liberty, and appointed to a command against the Protestants. His request was granted, and in 1636 he entered Franche-Comté, and after capturing several places laid siege to Dôle. The town made a vigorous resistance, and Condé was forced to raise the siege. He was equally unsuccessful at the siege of Fuenterrabia in 1638, but took Salces in 1639, and Elne in 1642. After the death of Louis XIII. he was admitted to the council of regency, in which he rendered signal services. "But his greatest glory," says Voltaire, "was to be the father of the great Condé." **IV. Louis II. de Bourbon,** the great Condé, son of the preceding, born in the castle of Vincennes, Sept. 8, 1621, died at Chantilly, Dec. 11, 1686. After receiving a thorough education, he entered the military service and signalized himself by unusual intrepidity and fierceness of temper. When only 22 years old, and known as the duke d'Enghien, he was placed in command of the French army in Flanders. Contrary to the advice of the old generals who served under his orders, he gave battle to the Spaniards at Rocroy, May 19, 1643, and through skilful manœuvres, and the impetuosity of his attacks, overpowered them; thus inaugurating by a brilliant victory the reign of Louis XIV. In 1644, being sent to Germany, he fought for three days in succession against the Bavarian Gen. Mercy, near Freiburg, and forced him to retreat. In 1645 he again met his rival Gen. Mercy at Nördlingen, and engaged in a terrific conflict, during which Mercy was killed, while Condé himself was wounded, but finally achieved another triumph. In 1646 he returned to Flanders, and took Dunkirk; but the following year, in Spain, he was foiled in the siege of Lérida, and his past exploits did not shield him against ridicule and satire. But these were soon silenced by another great success, Aug. 20, 1648, at Lens in Flanders. There he completed the destruction of that formidable Spanish infantry which had received the first deadly blow at Rocroy; and a still more important object was gained, this victory bringing about the end of the thirty years' war, and the peace of Westphalia, signed by France Oct. 24, 1648. At the beginning of the war of the Fronde in the next year, he for a while sided with the court against the parliament and the lords, and after a three months' siege succeeded in reinstating the young king in Paris; but dissatisfied with the reward of this service, he acted with an overbearing superciliousness which was imitated by his followers, and caused them to be styled *petits maîtres*. Queen Anne of Austria and Mazarin, being resolved to get rid of so despotic an auxiliary, became reconciled for a while with the chiefs of the Fronde, and had the prince arrested, in company with his brother and brother-in-law, Conti and Longueville, Jan. 18, 1650. Liberated by Mazarin, who was obliged to leave the kingdom, he repaired to Bordeaux, which city had already revolted in his behalf. He was worsted by several royalist chiefs, and especially by Turenne. The first important engagement between the two great rivals took place April 7, 1652, near Bléneau on the Loire, where, notwithstanding the numerical inferiority of his troops, Turenne conquered. "You have for the second time placed the crown of France on the head of my son," said Anne of Austria, in congratulating him upon his success. Three months later, July 2, another battle was fought under the walls of Paris in the faubourg St. Antoine, and Condé would have been entirely defeated had not the duchess de Montpensier, then in Paris, caused the gates of the metropolis to be opened, and the artillery of the Bastile to play upon the royal army. But Paris, the parliament, and nearly all the Frondeurs were tired of the protracted struggle; and it was in vain that Condé urged them to prolong their resistance. They made their peace with the queen, and the prince had now no other alternative than to go over to the Spaniards in the Netherlands. The French hero was now seen in the ranks of those against whom he had been so fiercely arrayed, fighting against his own countrymen. But fortune seemed to have deserted him; he shared in the defeats inflicted by Turenne upon his allies at Arras in 1654, and near Dunkirk in 1658. On the conclusion of the treaty of the Pyrenees in 1659, he was pardoned and allowed to return to France, where he lived at his magnificent country seat of Chantilly. Eight years afterward he was recalled to active service, and early in 1668 conquered Franche-Comté within less than three weeks. This reinstated him with the king, but not sufficiently to make the latter support him as a candidate for the crown of Poland after the abdication of John Casimir. In 1672, on the outbreak of the war against the United Provinces, Condé was placed at the head of one of the armies which invaded the Netherlands, and was wounded in the arm at the crossing of the Rhine. He afterward opposed William of Orange, whom he fought at Senef, Aug. 11, 1674, with doubtful success. The next year he was called to Alsace to command another French army which had been entirely disorganized by the death of Turenne; he restored order, and drove Montecuculi beyond the Rhine. This was his last triumph, the infirmities consequent upon his long campaigns forcing him to retire. He repaired to Chantilly, where he was surrounded by a crowd of followers; here also he frequently received the most illustrious poets of his time, Racine, Molière, La Fontaine, and Boileau. In his latter years he was especially fond of the society of Bossuet, who was his spiritual adviser, and whose funeral oration describes in a most eloquent manner the military life and Christian death of the illustrious warrior.—See *Essai sur la vie du grand Condé*, by Louis Joseph de Bourbon, prince de Condé (London,

1806); "Life of the Great Condé," by Lord Mahon (London, 1840); *Histoire du grand Condé*, by Lemercier (Tours, 1844); and *Histoire du grand Condé*, by Voivreuil (Tours, 1847). **V. Henri Jules de Bourbon,** prince de, son of the preceding, born in 1643, died April 1, 1709. In 1650, while his father was in prison, a royal order was received that the duchess and her son, then known as the duke d'Enghien, should be conveyed to Berry. A servant, personating her mistress, detained the royal messenger while the duke and his mother took flight to Bordeaux. After many adventures the duke in 1654 rejoined his father in the Netherlands, and commenced a brilliant career in arms. In 1663 he married Anne of Bavaria, princess palatine of the Rhine. He served in the army of Flanders in 1667, in Franche-Comté in 1668, and in Holland in 1672. In 1674 he saved the life of his father at Senef, and in 1675 captured Limburg. In his later years he manifested strange humors; his avarice and the excessive care which he took of his health rendered him the laughing-stock of the court. **VI. Louis III. de Bourbon,** duke de Bourbon-Condé, son of the preceding, born in 1668, died in Paris, March 4, 1710. He was grand master of the royal household, governor of Burgundy, and manifested military capacity equal to that of his grandfather, the great Condé; but he never held the chief command of an army. He took part in the siege of Philippsburg under the orders of the dauphin, in that of Mons under the king, and in that of Namur in 1692. He distinguished himself at the battles of Steenkerke, 1692, and Neerwinden, 1693, and in the campaign of Flanders in 1694. He died suddenly. **VII. Louis Henri de Bourbon,** duke de Bourbon and Enghien, son of the preceding. See Bourbon, Louis Henri. **VIII. Louis Joseph de Bourbon,** prince de Condé, son of the preceding, born at Chantilly, Aug. 9, 1736, died in Paris, May 13, 1818. He was three years old when his father, the duke de Bourbon, late minister of Louis XV., left him an orphan. He distinguished himself during the seven years' war, especially at the battle of Johannisberg, Aug. 30, 1762. His life at the commencement of the revolution was marked by many acts of munificence and liberality; but after the taking of the Bastile he was among those who at once emigrated, and, with the count d'Artois, organized on the banks of the Rhine the French army of emigrants, afterward styled *armée de Condé*. This body, in concert with the Austrian army with which it was incorporated, took an active part in the campaign of 1793 on the banks of the Rhine. In 1795 the prince entered into secret negotiations with Pichegru, who was in command of the republican French army, but without success. The army of Condé, increased to 10,000 men in 1796, received their pay from England, although continuing to operate with the Austrian troops. After the peace of Campo Formio in 1797, Condé repaired to Russia, and took part with the Russians in the campaign of 1799 in Switzerland; afterward with the Austrians in that of 1800; and finally retired to England in June, 1801. On the restoration he returned to France with Louis XVIII., who appointed him colonel general of the infantry and grand master of the royal household. He resided at Paris in the Palais Bourbon, but more frequently at Chantilly. He wrote *Essai sur la vie du grand Condé* (London, 1806), reprinted in the *Mémoires de la maison de Condé*, published by Sévelinges in 1820. **IX. Louis Henri Joseph de Bourbon,** duke de Bourbon, and the last prince de Condé, son of the preceding. See Bourbon, Louis Henri Joseph. **X. Louise Adélaïde de Bourbon,** sister of the preceding, distinguished for her piety, born at Chantilly, Oct. 5, 1757, died in Paris, March 10, 1824. Having emigrated with her family during the revolution, she became an inmate of the Carmelite nunnery of Turin, and took the veil, Sept. 27, 1797, at a convent in Switzerland. On the arrival of the republican army in that country she fled to Russia, and eventually found a refuge at Warsaw. When she heard of the death of her nephew the duke d'Enghien, she repaired to England to comfort his father; and from 1815 to the time of her death she resided in Paris, where the king presented her with the *maison du Temple*. She established here the religious order of the *adoration perpétuelle*, of which she had been a member during her stay at Warsaw, under the name of Marie Louise de la Miséricorde. The letters written by her in 1786–'7, to M. de la Gervaisais (an officer for whom in her early days she had conceived a Platonic love), were published by M. Ballanche in 1834.—See *Histoire des princes de Condé*, by the duke d'Aumale (2 vols., Paris, 1869), translated into English by Robert Brown-Borthwick (2 vols., London, 1872).

CONDE, José Antonio, a Spanish orientalist and historian, born at Paraleja, in the province of Cuenca, about 1765, died in Madrid in 1820 or 1821. He was educated at Alcalá, applied himself to the study of oriental languages, and obtained employment at the royal library of Madrid. Joseph Bonaparte appointed him chief librarian. When the French were driven from Spain, he repaired to Paris, but subsequently returned to Madrid. He wrote a *Descripcion de España* (1799), and *Historia de la dominacion de los Arabes en España* (3 vols. fol., with plates, Madrid, 1820–'21; 8vo, Paris, 1840; translated into French by Marlès, into German by Kuttschmann, 1824–'5, and into English by Mrs. Jonathan Forster, 1854).

CONDER, Josiah, an English publisher and author, born in London, Sept. 17, 1789, died Dec. 27, 1855. In 1814 he purchased the "Eclectic Review," which he edited till 1837. In 1824 the "Modern Traveller" was commenced, extending to 33 volumes, nearly all of which were compiled by Mr. Conder. In 1832 he became editor of the "Patriot," a news-

paper in the dissenting interest, which he conducted until his death. Among his works are "Protestant Nonconformity" (2 vols.), "The Star in the East," a poem, and "An Analytical and Comparative View of all Religions."

CONDILLAC, Étienne Bonnot de, a French philosopher, born at Grenoble, Sept. 30, 1715, died Aug. 3, 1780. In early youth his constitution was so feeble that he could not be kept at school; at 12 years of age he was not able to read. After having improved in health, he devoted himself to science, and became the tutor of the heir apparent of Parma, a nephew of Louis XV. Having completed the prince's education, he returned to Paris, and subsequently retired to an estate near Beaugency, where he spent the rest of his life. He was a quiet, unpretending scholar. In his philosophy he started from the ideas of Gassendi and Hobbes, and from the psychological researches of Locke, but enlarged and modified them to such a degree that his claims to originality have not been seriously contested. His theories were highly esteemed for their clearness and simplicity, and were widely propagated by the encyclopædists. In his *Essai sur l'origine des connaissances humaines* (Amsterdam, 1746), he maintained the following propositions: 1. All our ideas originate in sensations; there are no innate ideas. 2. Not only our ideas but all faculties of the human soul proceed from transformed sensations; the intellectual faculties (attention, comparison, judgment, reflection, imagination, and the reasoning power) from sensations so far as they represent external objects; the faculties of volition (need, desire, passion, and resolution) from sensations so far as they affect the subject. 3. The intellectual action consists merely in the connection and combination of ideas. 4. Left to itself, unaided by the senses, the human mind is void and powerless. Whatever progress it has made is owing to the use of signs and articulated sounds. Thinking is nothing without language. Languages are analytical methods. To them we owe most of our ideas, which have no reality except by the words or signs representing them. 5. In reasoning, proof is afforded by identity. The demonstration of such identity is facilitated by the close analogy of words. Hence science is not much more than language, and a correct science depends upon a correct language, adapted as closely as possible to the different modifications and gradations of perception. 6. The only method leading to the knowledge of truth is the analytic one, the close and logical observation of all parts of an object, so that the mind may comprehend them simultaneously, and understand their common principle. Synthesis, beginning with definitions and abstract generalities, is useless, since it generates chimeras and errors. Condillac, although reducing all the faculties of the soul to mere transformations of sensation, does not belong to the materialist school proper. Unlike La Mettrie and his followers, he does not consider sensation as a mere physical process, and assumes the immaterial nature of the soul. In his *Traité des systèmes* (1749) he endeavored to show that all metaphysical systems are based upon arbitrary assumptions, shallow quibbles, or empty abstractions. The "innate ideas" of Descartes, the "ideas of God" of Malebranche, the "monads" of Leibnitz, the "infinite substance" of Spinoza, are all mercilessly dissected by Condillac, and exposed as chimeras. His *Traité des sensations* (1754) is an ingenious demonstration of the psychological process by which sensations are developed into ideas and self-consciousness. In this book Condillac exhibits a human form as yet entirely inanimate, and then adding successively the senses, he goes on to show what kind of sensations are produced by the one and the other; how by the repetition or combination of these sensations ideas are begot; again, how these ideas are interwoven, and new combinations formed, every succeeding one more remote from and apparently independent of the original sensitive impressions. The idea of considering the human mind first as a *tabula rasa*, and then observing the action of the senses upon it, was not entirely new; it had been used before by Bonnet, Diderot, and Buffon. The original manner, therefore, in which this idea had been used by Condillac did not save him from the reproach of having mechanically imitated Buffon. To show the untruth of this, he wrote his *Traité des animaux* (1755), in which he refuted many of Buffon's doctrines by the very principles laid down in the *Traité des sensations*. While tutor of the prince of Parma, Condillac composed the *Cours d'études*, in three volumes, intended as a kind of cyclopædia of philosophical and historical science, but chiefly remarkable for the ingenious investigation of the signs and words representing sensations and ideas. Another work, *Le commerce et le gouvernement considérés relativement l'un à l'autre* (1776), being an application of his analytic method to political and economical doctrines, was not successful. Having been requested by the board of education of Poland to assist in the organization of public education in that country, Condillac wrote his *Logique* (published in 1781), as a manual for schools. An incomplete work, *La langue des calculs*, in which he had proposed to demonstrate that all sciences might be rendered as positive and exact as mathematics, was published in 1798 by Laromiguière. Several editions of the complete works of Condillac have been published in Paris (23 vols., 1798; 32 vols., 1803; 16 vols., 1821).

CONDOM, a town of France, in the department of Gers, on the river Bayse, which is here crossed by two bridges, 24 m. N. N. W. of Auch; pop. in 1866, 8,140. It has manufactories of cotton, mixed fabrics, and earthenware, and carries on a brisk trade with Bordeaux in agricultural produce. There is a handsome Gothic church of the 16th century, and a communal college. It was formerly the

seat of a bishopric, which was for some time filled by Bossuet. Dupleix and Salvandy were born there.

CONDOR (*sarcoramphus gryphus*), a large bird of prey, belonging to the order *raptores,* family *vulturidæ.* In the genus *sarcoramphus,* which includes two species, both peculiar to the American continent, the bill is moderate, covered for about one third of its length with a soft cere, and arched to its strong and sharp tip; the nostrils are large and exposed in the middle of the cere, and in the male furnished with a caruncle; the wings are long and pointed, with the third and fourth quills equal and the longest; the tail is moderate and even at the end; the tarsi are plumed below the knee, and covered with small reticulated scales; the toes are moderate and united by a slight membrane; the hind toe is the shortest and is weak; the claws are strong and slightly curved; the head, neck, and front of the breast are bare of feathers, and covered with a hard, dry, and wrinkled skin, with a few short, stiff, and dark-

Condor (Sarcoramphus gryphus).

colored hairs. On the summit of the head, in the male only, is a fleshy or cartilaginous crest, extending over the posterior part of the beak, and sloped anteriorly so as not to cover the nostrils; this crest, unlike that of the gallinaceous birds, is hard, with very few vessels, and incapable of inflation. The head is flat; the beak whitish at the tip, and brownish at the base. The rough skin of the head and neck is formed into folds, somewhat as in the turkey, which may be swelled out at pleasure; these wrinkles arise from the habit of contracting its neck within the collar. The naked neck is separated from the feathered body by a collar of fine and white silken down; this collar is found in the adults of both sexes. The general color of the plumage is brownish black; the primaries are black; the secondaries are nearly half white, so that, in the males especially, the wing is adorned with a white spot, which has led some naturalists into the erroneous belief that the back is white, from the appearance of this color when the bird is hovering below the observer. The feathers are not so thick on the under surface of the body, but those of the thighs are long. The only noise it makes is a hiss like that of a goose. The most extravagant ideas prevailed concerning the size of the condor until the visit of Humboldt to South America. The average length of this bird, from the point of the beak to the end of the tail, is not more than 3½ ft., and the spread of the wings from 9 to 10 ft.; some individuals, from favorable circumstances, may attain an extent of wings of 12 or 13 ft. A full-grown male from the most celebrated locality on the Andes, now in Vassar college, has a stretch of 9 ft. Humboldt never found one to measure over 9 ft., and the largest specimen seen by Darwin was 8½ ft. from tip to tip. An old male in the zoölogical gardens of London measures 11 ft. The exaggerated accounts of its size have doubtless originated from the difficulty of accurate observation in the solitary and almost inaccessible retreats which the condor prefers; it is most frequently seen either perched upon a lofty mountain peak, or soaring at an immense height. With this idea of its gigantic size, it is natural that travellers should believe and report tales of its strength and ferocity in attacking and carrying off man and large animals. Its beak and claws are very strong, but are employed in tearing dead rather than living animals. Humboldt could not ascertain that these birds had ever carried off a child, and believed that the reports of their killing young persons are as fabulous as those concerning the great noise made in their flight. Still, with their great strength, there is no doubt that condors might destroy children and even man; they have been seen to attack young bulls, and tear out their tongue and eyes. Nevertheless, the natives of the Andes uniformly assert that they are not dangerous to man, and even leave their young children asleep in the open air without fear of their being carried off. The true condor belongs exclusively to the chain of the Andes, from the straits of Magellan to a few degrees north of the equator. Condors generally live in pairs, in the most elevated and solitary localities; from these they descend into the valleys and plains in search of food, generally the carcasses of large animals. Their ordinary habitat is between the altitudes of 10,000 and 16,000 ft. The largest seem to make their home around the volcano of Cayambe, which stands exactly on the equator. In the rainy season they frequently descend to the coast, where they may be seen roosting on trees. They are most commonly seen around vertical cliffs, where their nests are, and where cattle are most likely to fall. Great numbers frequent Antisana, where there is an extensive cattle estate. When gorged with food, they retire to their ledges to digest it. As summer approaches, they seek the most inaccessible crags to rear their young; the female makes no nest,

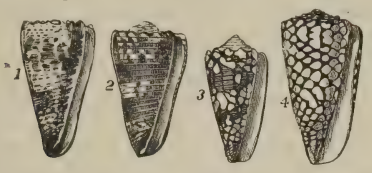
but deposits two white eggs, about four inches long, upon the bare rock, placing a few sticks around them. Incubation occupies about seven weeks, ending in April or May. The young are scarcely covered with a dirty-white down, and they are not able to fly for nearly two years. They are as downy as goslings until they nearly equal in size a full-grown bird. The white frill at the base of the neck, and the white feathers in the wings, do not appear until the second plumage, or until after the first general moulting, during which time they lie in the caves and are fed by their elders for at least six months. Previous to this the frill is of a deep gray color and the wing feathers brown. The claws of the condor are nearly straight, and it prefers alighting on the ground to perching in trees. They often hunt in pairs, and two will not hesitate to attack the largest animals, pursuing them, and tearing them with beak and talons until they expire. There is no doubt that the condor detects its prey almost entirely by the sense of vision; when stimulated by hunger, it flies to a great height for the purpose of taking in at a glance a vast extent of country. Thus, though a carrion bird, it breathes the purest air, spending much of its time at a height of three miles above the sea. Humboldt saw one fly over Chimborazo, and Orton says he has seen them sailing 1,000 ft. above the crater of Pichincha. It is often seen singly soaring at a great height in vast circles; its flight is slow and majestic; its head is constantly in motion, as if in search of food below; its mouth is kept open and its tail spread. From its large and exposed nostrils, as compared with the smaller and covered ones of the birds preying exclusively on living animals, it is possible that the condor is to some extent guided to its favorite food by the sense of smell; but, from the careful experiments of Audubon with other species of vulture, it is most likely, as he suggests, that the large openings of the nostrils are for the purpose of permitting the bird to clear out this avenue of respiration while its beak is plunged in the filthy matters which it devours. From the inactivity of the condor when gorged with food has arisen the favorite native method of taking it alive. A horse or cow being killed, the condors soon make their appearance and attack the carcass, beginning with the eyes and tongue, their favorite morsels; in order to arrive the quickest at the intestines of the animal, they direct their principal efforts to the anus; when satiated and unable to mount, the Indians pursue and capture them with ease. To rise from the ground it must run for some distance; then it flaps its wings three or four times, and ascends at a low angle till it reaches a considerable elevation, when it seems to make a few leisurely strokes, as if to ease its wings, after which it literally sails upon the air. In walking, the wings trail on the ground, and the head takes a crouching position; it has a very awkward, almost painful gait. From its inability to rise without running, a narrow pen is sufficient to imprison it. In captivity it will eat almost anything but pork and cooked meat; a single condor of moderate size has been known to eat in one week a calf, a sheep, and a dog. In confinement they are mischievous and ferocious; they are very hard to kill, from the difficulty of penetrating their thick plumage, and they appear to have more tenacity of life than any other birds of prey.—The second species of the genus, the king vulture (*S. papa*), called condor in Mexico and Central America, and intimately connected with the mythology of the Aztecs, is about as large as a goose, and frequents more especially the plains of the Pacific coasts of America from 32° S. to 30° N.; but it is most numerous in the torrid zone. The skin of the head and neck is of a bright red color, bare of feathers, wrinkled, with a few hairs on the occiput, and a frill of plumes below the naked portion of the neck large enough to conceal a great part of the head when the bird draws itself into its favorite contracted, half-inclined position. Between the nostrils rises a soft crest, indented like the comb of a cock, and terminating in wart-like protuberances. The general color of the plumage is white, whence the Spaniards of Paraguay called it the white crow; the wing coverts, wings, tail, a part of the back, the bill, and the tarsi are black; in some specimens the naked skin of the head and neck is variegated with tints of orange, purple, and red. The immature birds have much more black in their plumage. The king vulture resembles the condor in its habits; it is a shy bird, unless pressed by hunger and in the vicinity of carrion; it is said to build its nest in a hollow tree, and to deposit two eggs. It received the name of king vulture, because from its superior size and strength it readily put to flight the carrion crows and turkey buzzards when congregated about a carcass upon which it desired to feed.

CONDORCET, Marie Jean Antoine Nicolas Caritat, marquis de, a French savant, born at Ribemont, near St. Quentin, Sept. 17, 1743, died at Bourg-la-Reine, March 28, 1794. He received his education at the collége de Navarre, and being introduced at the age of 19 to the court of Louis XV., his strict morality and earnest love of science kept him pure from the pernicious influences of that dangerous region. His essay *Sur le calcul intégral* and some similar writings were rewarded by his election, at the age of 26, to the academy of sciences, of which in 1777 he was elected secretary. His ingenuity in handling the most difficult mathematical problems was equalled by his versatility. In 1777 a premium was awarded to him by the Berlin academy of science for his theory of comets. An intimate friend of Turgot, Condorcet made himself familiar with the systems of political economy; at the same time he became an active contributor to the

Encyclopédie of Diderot and D'Alembert. He was a zealous advocate of the cause of the American colonies, and of the gradual emancipation of negro slaves, to be preceded, however, by their education. The French revolution found him, although belonging to the higher ranks of nobility and a friend of the duke de Rochefoucauld, among the defenders of the popular cause. To his fame as a mathematician he now added that of a political writer. The boldness of thought which had distinguished his scientific researches characterized his political pamphlets and speeches. While in his *Feuille villageoise* he explained the fundamental principles of politics and public economy in plain and lucid language, adapted to the understanding of the masses, he rivalled the best orators of his time in his speeches as a member of the legislative assembly. The speech in which, after the attempted escape of the king, he represented monarchy as an anti-social institution, was admired as a model of eloquence and conclusive argument. He was elected secretary, and in 1792 president of the legislative assembly. The address of the French people to the nations of Europe on the abolition of monarchy was written by Condorcet. As a member of the national convention, he sided with the Girondists or moderate republicans. When the king was impeached by the convention, Condorcet voted for the severest penalty short of capital punishment, the total abolition of which he had always advocated. To him was intrusted the work of preparing a new constitution, but the downfall of the Girondists (May 31, 1793) prevented its completion. Nothing daunted by the reign of terror, he energetically denounced the extreme measures adopted by the committee of public safety. Indicted as an accomplice of Brissot (Oct. 3), he retired from public notice to save his life, and was in consequence declared an outlaw. For months he was secreted by Mme. Vernet. During that time he wrote his *Esquisse d'un tableau historique des progrès de l'esprit humain*, and the *Épître d'un Polonais exilé en Sibérie à sa femme*. When by a stray newspaper he learned that all who sheltered outlaws were to forfeit their own lives, he left his asylum in spite of the entreaties of Mme. Vernet, fled from Paris in disguise, and wandered about for some time until starvation compelled him to ask for food in an inn at Clamart (March 27, 1794). Here he met with a member of the local revolutionary tribunal, who had him arrested and committed on suspicion without even knowing his name. The next morning he was found in his prison a corpse. The general opinion is that he voluntarily put an end to his life by a dose of poison which he had carried with him for some time. His complete works have been edited by Garat and Cabanis (22 vols., Paris, 1804). After the establishment of the republic in 1870, the *lycée impérial* received the name of the *lycée Condorcet*.—His wife, Marie Louise Sophie de, a sister of Marshal Grouchy and Mme. Cabanis, took a lively interest in his philosophical researches, and wrote herself some works which are not without merit. She also translated into French Adam Smith's "Theory of Moral Sentiments" (Paris, 1798). She was born in 1765, and died Sept. 6, 1822.

CONDOTTIERI (Ital., conductors), the common designation of adventurers who, principally in Italy, during the 14th and 15th centuries, kept bands of soldiers which they hired out to the party that paid best. The burghers of the Italian municipalities, having by their control of the commerce with Asia become wealthy and prosperous, were slow to take up arms and risk their lives and fortunes for every petty quarrel with neighboring states. Hence they hired others to fight for them, not for a certain term of years, but by the job. The condottieri, then, were a kind of contractors, who, when a war was impending, made their bids accordingly. Having underbid one another in price, they not unfrequently increased their pay by plunder and booty. When the job was finished, they were loath to discharge their bands, but in order to keep them together they were compelled to fight and plunder on their own account. There was a kind of good fellowship between the condottieri, which they observed even when fighting under different colors. When one party was hired to put down another, the result generally was only a bloodless fight, the peaceable citizens being the only sufferers. Among themselves they had rules of warfare of their own. For instance, when they made a prisoner of their own class, they merely relieved him of the valuables he carried on his person and set him free without requiring ransom, while every outsider was made to pay heavily for his liberation. In the 15th century their wars were frequently mere shams. Thus, at a great battle near Zagonera in 1423, there were only three men killed; and in 1467 a battle was fought near Molinella between the condottieri of the pope and those of Naples, in which there was not even a single man hurt. Not infrequently they changed their allegiance on the very field of battle when they were offered better pay by the enemy; nor did they hesitate to double or treble the price agreed upon after every real or sham victory.

CONE, in geometry, a solid figure described by a straight line moving in such a way that it always passes through a given curve enclosing a portion of a plane and through a fixed point not in that plane. The fixed point is called the vertex of the cone, and the portion of the plane enclosed by the given curve is called the base of the cone. When the base is a circle, and the line drawn from the vertex to the centre of the circle is perpendicular to the plane of the circle, the figure is called a right cone. If the line drawn from the vertex to the centre of the base is not perpendicular to the plane of the base, the figure is called an oblique cone. So if a right-angled



triangle be revolved about one of the sides forming the right angle, the other side will describe a circle and the hypothenuse will describe a right cone. In popular usage the cone is considered as limited to that portion of the figure between the vertex and the base; but in mathematics the line describing the cone is supposed to extend indefinitely beyond the base, and the mathematical cone is consequently a figure of boundless extent. Every straight line drawn from the vertex through the curve enclosing the base is called a side of the cone. Every such line of course represents one of the positions of the line by which the cone is supposed to have been described. The distance from the vertex to the base measured on any one of these lines is called the slant height. The perpendicular distance from the vertex to the plane of the base is called the altitude of the cone. The study of the right cone is sufficient for most practical and scientific purposes. (See Conic Sections.) The area of the surface of a right cone is equal to one half the circumference of the base multiplied by the slant height. The volume or solidity of a right cone is equal to one third the area of the base multiplied by the altitude.—The name cone is given to the fruit of the pines and larches, from their resemblance to this figure.

CONE, Spencer Houghton, D. D., an American clergyman, born in Princeton, N. J., April 30, 1785, died in New York, Aug. 28, 1855. At the age of 12 he entered Princeton college, but two years later the infirm health of his father made him the only support of a large family, and he became Latin teacher in the Princeton academy. He afterward taught school at Burlington, N. J., and subsequently in Philadelphia, where he enfeebled his health by the combined labors of teacher, law student, and copyist. One of his friends, an Episcopal bishop, advised him to take orders in the Episcopal church, from which, however, he was withheld by the fact that he was a Baptist, and of a family which had been Baptist during many generations. The next advice of the bishop was that he should avail himself of his remarkable voice, and other superior physical qualifications, by going upon the stage. This he prepared to do, and in 1805 he appeared in the old Chestnut street theatre, Philadelphia, and at once took considerable rank. For seven years he followed this profession with great success, chiefly at Philadelphia, Baltimore, and Alexandria. In 1812 the lady to whom he was engaged refused to marry him unless he abandoned the stage; which he did, and became editor of the "Baltimore American" newspaper. He soon after joined a regiment and served against the British in the engagements connected with their attacks on Baltimore and Washington. At the instance of George M. Dallas, whose father was secretary of the treasury, he obtained an appointment at Washington; and as he now contemplated the Christian ministry, he began to preach in some of the neighboring churches. He immediately excited general interest, attracted thronging audiences, and was chosen chaplain to the congress of 1815–'16. He was settled in Alexandria until 1823, when he accepted a call to the Oliver street Baptist church in New York city, of which society he held the pastorate till 1841, when he exchanged it for that of the first Baptist church in the same city, which he retained till his death. He was a leading member of the Baptist general convention of the United States, and became its president in 1832; was foremost in directing the measures of the societies of home and foreign missions; took part in the discussions which resulted in the secession from the American Bible society of the American and foreign Bible Society, of which he was chosen president; and in 1850 was one of the authors of a tract calling for a new translation of the Bible, more definitely in accordance with Baptist views, which occasioned an exciting controversy within the Baptist body. The result of the discussion, however, was that the proposal was negatived, and then Dr. Cone prompted the formation of the American Bible union, of which he was made president. A memoir of his life was written by his sons, and published in New York in 1856.

CONECUH, a S. county of Alabama, drained by Escambia river, Burnt Corn creek, Murder creek, and Sepulgah river; pop. in 1870, 9,574, of whom 4,901 were colored. The former area was 1,430 sq. m., but a portion has recently been taken to form Escambia county. It has a hilly surface, with a sandy, sterile soil. The forests furnish large quantities of pine timber, which are conveyed down the Conecuh in small rafts. Near Brooklyn, in the E. part, is a large cave. The Mobile and Montgomery railroad passes through the county. The chief productions in 1870 were 92,177 bushels of Indian corn, 12,550 of sweet potatoes, and 1,539 bales of cotton. There were 425 horses, 1,769 milch cows, 2,298 sheep, and 4,433 swine. Capital, Sparta.

CONEJOS, the S. W. county of Colorado, bounded N. E. and E. by the Rio Grande, which also intersects the N. part, S. by New Mexico, and W. by Utah; area, over 11,000 sq. m.; pop. in 1870, 2,504. It is watered by the Conejos and other tributaries of the Rio Grande, and also by tributaries of the San Juan. The surface is broken by mountains, the Sierra Madre and Sierra La Plata ranges traversing the county. There is a large area of arable land. The W. part is occupied by the Ute Indian reservation. The precious metals are found in the mountainous parts, but are little worked. Gypsum also occurs. The inhabitants are chiefly Mexicans and half-breeds. The chief productions in 1870 were 9,222 bushels of wheat, 852 of oats, 2,001 of potatoes, and 71,076 lbs. of wool. There were 548 horses, 1,791 milch cows, 2,178 other cattle, and 35,538 sheep. Capital, Guadalupe.

CONE SHELLS, univalve shells of the genus *conus*, comprising many species and varieties. The shell is very thick, and appears as if rolled up in conical form. The outer lip

1. Conus imperialis. 2. C. zonatus. 3. C. nocturnus. 4. C. marmoreus.

is simple and sharp-edged, the inner lip is smooth. The spire is frequently very flat. The mollusk has a distinct head, with gills, a long proboscis, and a pair of tentacula bearing eyes. A horny operculum closes the opening of the shell. The cones are many of them very beautiful both in form and colors, and some specimens bring a high price. They are mostly found in tropical seas, but some are met with in the Mediterranean. They live in fissures and holes in rocks, and especially in the warm pools and on the sandy bottoms inside coral reefs, at depths varying from a few feet to 30 fathoms. They move slowly, and are all predatory; some will bite when handled. Some fossil species occur in the tertiary formation.

CONESTOGAS, or **Gandastogués,** a tribe of Indians formerly on the Susquehanna river, commonly called by the French Andastes, by the people of Virginia and Maryland Susquehannas, and by the Dutch and Swedes Minquas. They were of the same family as the Hurons and Iroquois, and their name Gandastogués meant nation of roof poles. Before 1600 they nearly exterminated the Mohawks in a ten years' war, and were still at war with them in 1608, when Capt. Smith met a party of Susquehannas on Chesapeake bay. They held in subjection all the neighboring Algonquin tribes, and were at war with those of Maryland. Acquiring firearms and cannon from the Swedes, they were so troublesome to Maryland that Gov. Calvert proclaimed them public enemies in 1642. They were friends and allies of the Hurons of Upper Canada, and offered to aid them with 1,300 warriors. In 1652 they ceded to Maryland lands on the Patuxent, Choptank, and Elk. In 1656 they were involved in war with the Iroquois, and though much reduced by smallpox, they fought desperately, gaining many victories over superior forces, but were completely overthrown in 1675. A part submitted to the Iroquois; others, retreating into Maryland, were attacked by Maryland and Virginia troops, who put five chiefs to death. The desperate Indians then ravaged the frontiers till they were cut off. In 1701 Canoodagtoh, their king, made a treaty with William Penn. They appear in a treaty in 1742, but were then fast disappearing. In 1763, during a period of excitement against the Indians, the remnant of the Conestogas took refuge in the jail at Lancaster, Pa., where they were cruelly butchered by an organization called the Paxton boys. The most distinguished of their chiefs was Logan, the famous orator. A vocabulary of their language was preserved in the works of the Swedish missionary Campanius, *Nye Sverige* and *Lutheri Catechismus* (Stockholm, 1696). A brief English account of them is in Alsop's "Maryland" (London, 1666; New York, 1869).

CONEWANGO CREEK, a stream which rises in the N. W. corner of Cattaraugus co., N. Y., flows in a general S. direction, receiving the waters of the outlet of Chautauqua lake, and joins the Alleghany river at Warren, Warren co., Pa. By means of this creek and its outlets there is boat navigation from the gulf of Mexico to within 10 m. of Lake Erie.

CONEY ISLAND, a barren strip of white sand at the S. W. extremity of Long Island, 9 m. S. of New York city, 1½ m. long and ½ m. broad. It is but slightly separated from the mainland. During the summer season it is much resorted to by pleasure-seekers, and on holidays especially is crowded by multitudes who flock from the neighboring cities to enjoy the sea air and bathing. It is connected by rail with Brooklyn, and by steamboats with New York.

CONFARREATION, the most solemn of the three ceremonies of marriage used among the ancient Romans. The other forms of marriage were *coemptio* and *usus*. These last are the only ones mentioned by Cicero, which shows that confarreation had fallen into disuse before his time. The ceremony was performed by the *pontifex maximus* or *flamen dialis*. A formula was pronounced in the presence of at least ten witnesses, and the man and woman partook of a cake of salted bread; part of which only they ate, the rest being thrown upon the sacrifice, which was a sheep. The cake was called *farreum* (from *far*, grain), whence *confarreatio*. By this form the woman was said to come into the possession of her husband by the sacred laws, and became a partner of all his substance and sacred rites, those of the penates as well as the lares. If the husband died intestate and without children, the wife inherited the whole property; if there were children, she received with them an equal share. The offspring of this form of marriage were called *patrimi* or *matrimi;* and from them were chosen priests and priestesses, especially the *flamen dialis* and vestal virgins. Tiberius wished for a priest of this pure lineage, but the ceremony had fallen into disuse, so that three patricians thus qualified could not be found. Confarreation could only be dissolved by a form of divorce equally solemn, called *disfarreatio*. Bride cake is a relic of confarreation; until within 200 years it was made of wheat or barley, without fruit.

CONFEDERATE STATES OF AMERICA, a confederacy formed by eleven southern and slaveholding states which seceded from the United States in 1860–'61, and organized a government terminating in 1865. In the presidential

election of 1860 all these states voted by heavy majorities for the democratic candidates; in none of them were any votes given for the republican candidates, except in Virginia, where they received fewer than 2,000 in a total poll of 167,000 votes. The first public act which took place having for its avowed object the formation of a southern confederacy was the call for a state convention in South Carolina. This was issued by the legislature on Nov. 7, 1860, the day after the presidential election, when it was known that a majority of the electors chosen on Nov. 6 were in favor of Lincoln and Hamlin, the republican candidates for president and vice president. The call summoned the convention to meet at Columbia on Dec. 17. Other measures were then adopted calculated to put the state in a position to meet the consequences of her action. The most important of these was a bill providing for an army of 10,000 men. A month later, on Dec. 10, Francis W. Pickens was chosen governor of the state by the legislature, and was at once inaugurated. In his inaugural address he thus explained the cause and the reasons for the secession of South Carolina: "For 73 years this state has been connected by a federal compact with co-states, under a bond of union for great national objects common to all. In recent years there has been a powerful party, organized upon principles of ambition and fanaticism, whose undisguised purpose is to divert the federal government from external and turn its power upon the internal interests and domestic institutions of these states. They have thus combined a party exclusively in the northern states, whose avowed objects not only endanger the peace, but the very existence of nearly one half of the states of this confederacy. And in the recent election for president and vice president of these states, they have carried the election upon principles that make it no longer safe for us to rely upon the powers of the federal government or the guarantees of the federal compact. This is the great overt act of the people in the northern states at the ballot box, in the exercise of their sovereign power at the polls, from which there is no higher appeal recognized under our system of government in its ordinary and habitual operations. They thus propose to inaugurate a chief magistrate, at the head of the army and navy, with vast powers, not to preside over the common interests and destinies of all the states alike, but upon issues of malignant hostility and uncompromising war to be waged upon the rights, the interests, and the peace of half the states of this Union. In the southern states there are two entirely distinct and separate races, and one has been held in subjection to the other by peaceful inheritance from worthy and patriotic ancestors; and all who know the races well know that it is the only form of government that can preserve both, and administer the blessings of civilization with order and in harmony. Anything tending to change and weaken the government and the subordination between the races, not only endangers the peace, but the very existence of our society itself. We have for years warned the northern people of the dangers they were producing by their wanton and lawless course. We have often appealed to our sister states of the south to act with us in concert upon some firm and moderate system by which we might be able to save the federal constitution, and yet feel safe under the general compact of union; but we could obtain no fair warning from the north, nor could we see any concerted plan proposed by any of our co-states of the south calculated to make us feel safe and secure. Under all these circumstances we now have no alternative left but to interpose our sovereign power as an independent state to protect the rights and ancient privileges of the people of South Carolina. This state was one of the original parties to the federal compact of union. We agreed to it, as a state, under peculiar circumstances, when we were surrounded with great external pressure, for purposes of national protection, and to advance the interests and general welfare of all the states equally and alike. And when it ceases to do this, it is no longer a perpetual union. It would be an absurdity to suppose it was a perpetual union for our ruin." The state convention assembled at Columbia on Dec. 17. Its president, David F. Jamison, said in his opening address: "If anything has been decided by the late election, it is that South Carolina must be taken out of this confederation in as speedy a manner as possible." He had no faith in any guarantees that might be offered by the north. They could offer none more solemn or more binding than the present constitution, and yet that sacred instrument had not protected them from aggression on the question of slavery. "Has it saved us from abolition petitions, intended to insult and annoy us on the very floors of congress? Has not that instrument been trodden under their very feet by every northern state, by placing on their books statutes nullifying the laws for the recovery of fugitive slaves?" Smallpox prevailing in Columbia, the convention after organizing adjourned to Charleston, where a committee was appointed to draft an ordinance of secession. The committee reported on Dec. 20 the following instrument:

"*An Ordinance to dissolve the Union between the State of South Carolina and other States united with her under the compact entitled 'The Constitution of the United States of America.'*

"We, the people of the state of South Carolina, in convention assembled, do declare and ordain, and it is hereby declared and ordained, that the ordinance adopted by us in convention on the twenty-third day of May, in the year of our Lord one thousand seven hundred and eighty-eight, whereby the constitution of the United States was ratified, and also all acts and parts of acts of the general assembly of the state ratifying amendments of the said constitution, are hereby repealed, and the union now subsisting between South Carolina and other states, under the name of 'The United States of America,' is hereby dissolved."

This ordinance was immediately passed by the unanimous vote of the convention, and was signed on the same day by its members in the presence of the governor and of both branches of the legislature. At the conclusion of the ceremonies the president of the convention formally proclaimed the state of South Carolina an independent commonwealth. On the following day a special committee appointed to draft a "declaration of the causes which justify the secession of South Carolina from the federal union" made a report in which those causes are thus stated:

"We assert that fifteen of the states have deliberately refused for years past to fulfil their constitutional obligations, and we refer to their own statutes for the proof. The constitution of the United States, in its fourth article, provides as follows: 'No person held to labor or service in one state, under the laws thereof, escaping into another, shall, in consequence of any law or regulation therein, be discharged from such service or labor, but shall be delivered up on claim of the party to whom such service or labor may be due.' This stipulation was so material to the compact that without it that compact would not have been made. The greater number of the contracting parties held slaves, and the state of Virginia had previously declared her estimate of its value by making it the condition of her cession of the territory which now composes the states north of the Ohio river. The same article of the constitution stipulates also for rendition by the several states of fugitives from justice from the other states. The general government, as the common agent, passed laws to carry into effect these stipulations of the states. For many years these laws were executed. But an increasing hostility on the part of the northern states to the institution of slavery has led to a disregard of their obligations, and the laws of the general government have ceased to effect the objects of the constitution. The states of Maine, New Hampshire, Vermont, Massachusetts, Connecticut, Rhode Island, New York, Pennsylvania, Illinois, Indiana, Ohio, Michigan, Wisconsin, and Iowa* have enacted laws which either nullify the acts of congress, or render useless any attempt to execute them. In many of these states the fugitive is discharged from the service or labor claimed, and in none of them has the state government complied with the stipulation made in the constitution. The state of New Jersey, at an early day, passed a law for the rendition of fugitive slaves in conformity with her constitutional undertaking, but the current of anti-slavery feeling has led her more recently to enact laws which render inoperative the remedies provided by her own law and by the laws of congress. In the state of New York even the right of transit for a slave has been denied by her tribunals; and the states of Ohio and Iowa have refused to surrender to justice fugitives charged with murder and with inciting servile insurrection in the state of Virginia. Thus the constitutional compact has been deliberately broken and disregarded by the non-slaveholding states, and the consequence follows that South Carolina is released from its obligation. The ends for which the constitution was framed are declared by itself to be 'to form a more perfect union, establish justice, insure domestic tranquillity, provide for the common defence, promote the common welfare, and secure the blessings of liberty to ourselves and our posterity.' These ends it endeavored to accomplish by a federal government, in which each state was recognized as an equal, and had separate control over its own institutions. The right of property in slaves was recognized by giving to free persons distinct political rights; by giving them the right to represent, and burdening them with direct taxes for, three fifths of their slaves; by authorizing the importation of slaves for twenty years; and by stipulating for the rendition of fugitives from labor. We affirm that these ends for which this government was instituted have been defeated, and the government itself has been made destructive of them by the action of the non-slaveholding states. Those states have assumed the right of deciding upon the propriety of our domestic institutions, and have denied the rights of property established in fifteen of the states and recognized by the constitution; they have denounced as sinful the institution of slavery; they have permitted the open establishment among them of societies whose avowed object is to disturb the peace and to eloin the property of the citizens of other states. They have encouraged and assisted thousands of our slaves to leave their homes; and those who remain have been incited by emissaries, books, and pictures to servile insurrection. For twenty-five years this agitation has been steadily increasing, until it has now secured to its aid the power of a common government. Observing the forms of the constitution, a sectional party has found within that article establishing the executive department the means of subverting the constitution itself. A geographical line has been drawn across the Union, and all the states north of that line have united in the election of a man to the high office of president of the United States whose opinions and purposes are hostile to slavery. He is to be intrusted with the administration of the common government, because he has declared that that 'government cannot endure permanently half slave, half free,' and that the public mind must rest in the belief that slavery is in the course of ultimate extinction. This sectional combination for the subversion of the constitution has been aided in some of the states by elevating to citizenship persons who, by the supreme law of the land, are incapable of becoming citizens; and votes have been used to inaugurate a new policy, hostile to the south, and destructive of its peace and safety."

* The enumeration of New York, Illinois, and Indiana among the states which had enacted personal liberty laws was an error. Those states had no such laws.

This address was adopted on Dec. 24 by a vote of 124 to 30, and on the same day the governor issued the following proclamation:

"*Whereas*, The good people of this state, in convention assembled, by an ordinance unanimously adopted and ratified on the twentieth day of December, in the year of our Lord one thousand eight hundred and sixty, repealed an ordinance of the people of this state adopted on the twenty-third day of May, in the year of our Lord one thousand seven hundred and eighty-eight, and have thereby dissolved the union between the state of South Carolina and other states under the name of the United States of America:

"I, therefore, as governor and commander-in-chief in and over the state of South Carolina, by virtue of authority in me vested, do hereby proclaim to the world that this state is, as she has a right to be, a separate, sovereign, free, and independent state, and as such has a right to levy war, conclude peace, negotiate treaties, leagues, or covenants, and to do all acts whatsoever that rightfully appertain to a free and independent state."

At this time, also, the state forces seized the United States custom house, post office, and arsenal in Charleston, and Forts Pinckney and Moultrie in the harbor of that city. Major Anderson, the United States commander, who had only about 80 men, withdrew his command from Fort Moultrie into Fort Sumter, which he considered more defensible. The convention on Dec. 25 appointed commissioners to visit the other slaveholding states and invite them to coöperate with South Carolina in the formation of a southern confederacy. Mississippi was the first to respond. Her convention passed the ordinance of secession on Jan. 9, by a vote of 84 to 15, which was subsequently made unanimous. Florida on the following day, Jan. 10, passed an ordinance of secession with a preamble declaring as a reason for the act, that "all hope of preserving the Union upon terms consistent with the safety and honor of the slaveholding states has been fully dissipated by the recent indications of the strength of the anti-slavery sentiment of the free states." The ordinance was passed by a vote of 62 to 7. Alabama was the next state to secede. Her chief city, Mobile, received the news of the secession of South Carolina with ringing of bells, firing of cannon, great gatherings in the streets, enthusiastic speeches, and every demonstration of joy. The governor, Andrew B. Moore, had already called a convention of delegates, elected Dec. 24, which assembled Jan. 7, 1861. All the counties of the state were represented. A strong Union sentiment was manifested by the members from

the northern part of the state. In spite of their opposition, however, the following ordinance of secession was carried by a vote of 61 to 39:

"*An Ordinance to dissolve the union between the state of Alabama and other states united under the compact styled 'the constitution of the United States of America.'*

"Whereas the election of Abraham Lincoln and Hannibal Hamlin to the offices of president and vice president of the United States of America, by a sectional party, avowedly hostile to the domestic institutions and to the peace and security of the people of the state of Alabama, preceded by many and dangerous infractions of the constitution of the United States by many of the states and people of the northern section, is a political wrong of so insulting and menacing a character as to justify the people of the state of Alabama in the adoption of prompt and decided measures for their future peace and security: Therefore,

"*Be it declared and ordained by the people of the state of Alabama in convention assembled*, That the state of Alabama now withdraws, and is hereby withdrawn, from the union known as 'the United States of America,' and henceforth ceases to be one of said United States, and is, and of right ought to be, a sovereign and independent state.

"Sec. 2. *Be it further declared and ordained by the people of the state of Alabama in convention assembled*, That all the powers over the territory of said state, and over the people thereof, heretofore delegated to the government of the United States of America, be, and they are hereby, withdrawn from said government, and are hereby resumed and vested in the people of the state of Alabama."

Georgia, the most populous and powerful of the cotton states, did not secede without considerable hesitation on the part of a large proportion of her people, nor without solemn warning and earnest remonstrance from her most distinguished citizen, Alexander H. Stephens, who on Nov. 11, 1860, addressed her legislature in Milledgeville, which was then the capital of the state, in opposition to the project of calling a secession state convention. His advice was not heeded. A convention was called, which was elected Jan. 4, 1861, and met at Milledgeville on the 16th. Mr. Stephens was a member, and on the second day of the session made a powerful and almost prophetic speech against secession, in which he said:

"This step, secession, once taken, can never be recalled, and all the baleful and withering consequences that must follow (as you will see) will rest on this convention for all coming time. When we and our posterity shall see our lovely south desolated by the demon of war, which this act of yours will inevitably provoke, when our green fields and waving harvests shall be trodden down by a murderous soldiery, and the fiery car of war sweeps over our land, our temples of justice laid in ashes, and every horror and desolation upon us, who but this convention will be held responsible for it, and who but him who shall have given his vote for this unwise and ill-timed measure shall be held to a strict account for this suicidal act by the present generation, and be cursed and execrated by posterity in all coming time for the wide and desolating ruin that will inevitably follow this act you now propose to perpetrate? Pause, I entreat you, and consider for a moment what reasons you can give that will satisfy yourselves in calmer moments—what reasons you can give to your fellow sufferers in the calamity that it will bring upon us. What reasons can you give to the nations of the earth to justify it? They will be calm and deliberate judges of this case, and to what cause or one overt act can you point on which to rest the plea of justification? What right has the north assailed? what interest of the south has been invaded? what justice has been denied? and what claim, founded in justice and right, has been unsatisfied? Can any of you name to-day one governmental act of wrong, deliberately and purposely done by the government at Washington, of which the south has a right to complain? I challenge an answer. On the other hand, let me show the facts (and believe me, gentlemen, I am not here the advocate of the north, but I am here the friend, the firm friend and lover of the south and her institutions, and for this reason I speak thus plainly and faithfully for yours, mine, and every other man's interest, the words of truth and soberness) of which I wish you to judge, and I will only state facts which are clear and undeniable, and which now stand in the authentic records of the history of our country. When we of the south demanded the slave trade, or the importation of Africans for the cultivation of our lands, did they not yield the right for twenty years? When we asked a three-fifths representation in congress for our section, was it not granted? When we demanded the return of any fugitive from justice, or the recovery of those persons owing labor or allegiance, was it not incorporated in the constitution, and again ratified and strengthened in the fugitive slave law of 1850? Do you reply that in many instances they have violated this compact, and have not been faithful to their engagements? As individuals and local communities they may have done so, but not by the sanction of government, for that has always been true to southern interests. Again, look at another fact. When we asked that more territory should be added, that we might spread the institution of slavery, did they not yield to our demands in giving us Louisiana, Florida, and Texas, out of which four states have been carved, and ample territory left for four more, to be added in due time, if you by this unwise and impolitic act do not destroy this hope, and perhaps by it lose all, and have your last slave wrenched from you by stern military rule, or by the vindictive decree of a universal emancipation, which may reasonably be expected to follow? But again, gentlemen, what have we to gain by this proposed change of our relation to the general government? We have always had the control of it, and can yet have if we remain in it, and are as united as we have been. We have had a majority of the presidents chosen from the south, as well as the control and management of most of those chosen from the north. We have had 60 years of southern presidents to their 24, thus controlling the executive department. So of the judges of the supreme court, we have had 18 from the south, and but 11 from the north. Although nearly four fifths of the judicial business has arisen in the free states, yet a majority of the court has always been from the south. This we have required, so as to guard against any interpretation of the constitution unfavorable to us. In like manner, we have been equally watchful over our interests in the legislative branch of the government. In choosing the presiding officer (*pro tem.*) of the senate we have had 24 and they 11; speakers of the house, we have had 23 and they 12. While the majority of the representatives, from their greater population, have always been from the north, yet we have generally secured the speaker, because he to a great extent shapes and controls the legislation of the country. Nor have we had less control in every other department of the general government. Attorney generals we have had 14, while the north have had but 5. Foreign ministers we have had 86, and they but 54. While three fourths of the business which demands diplomatic agents abroad is clearly from the free states, because of their greater commercial interests, we have, nevertheless, had the principal embassies, so as to secure the world markets for our cotton, tobacco, sugar, on the best possible terms. We have had a vast majority of the higher officers of both army and navy, while a larger proportion of the soldiers and sailors were drawn from the north. Equally so of clerks, auditors, and comptrollers filling the executive department; the records show for the last 50 years that of the 3,000 thus employed, we have had more than two thirds, while we have only one third of the white population of the republic. Again, look at another fact, and one, be assured, in which we have a great and vital interest; it is that of revenue, or means of supporting government. From official documents we learn that more than three fourths of the revenue collected has uniformly been raised from the north. Pause now, while you have the opportunity, to contemplate, carefully and candidly, these important things. Look at another necessary branch of government, and learn from stern statistical facts how matters stand in that department. I mean the mail and post-office privileges that we now enjoy under the general government, as it has been for years past. The expense for the transportation of the mail in the free states was, by the report of the postmaster general for 1860, a little over $13,000,000, while the income was $19,000,000. But in the slave states the transportation of the mail was $14,716,000, and the revenue from the mail only $8,000,265, leaving a deficit of $6,715,735 to be supplied by the north for our accommodation, and without which we must have been entirely cut off from this most essential branch of the government. Leaving out of view for the present the countless millions of dollars you must expend in a war with the north, with tens of thousands of your sons and brothers slain in battle and offered up as sacrifices on the altar of your ambition—for what? I ask again. Is it for the overthrow of the American government, established by our common ancestry, cemented and built up by their sweat and blood, and founded on the broad principles of right, justice, and humanity? I must declare to you here, as I have often done before, and it has also been declared by the greatest and wisest statesmen and patriots of this and other lands, that the American government is the best and freest of all governments, the most equal in its rights, the most just in its decisions, the most lenient in its measures, and the most inspiring in its principles, to elevate the race of men, that the sun of heaven ever shone upon. Now for you to attempt to over-

throw such a government as this, under which we have lived for more than three quarters of a century, in which we have gained our wealth, our standing as a nation, our domestic safety, while the elements of peril are around us, with peace and tranquillity, accompanied with unbounded prosperity and rights unassailed, is the height of madness, folly, and wickedness, to which I will neither lend my sanction nor my vote."

Notwithstanding this appeal, the convention on Jan. 19 passed an ordinance of secession by a vote of 208 to 89. A week later, on Jan. 26, Louisiana seceded by a vote of 113 to 17. Finally, on Feb. 1, Texas, in spite of the opposition of her governor, Sam Houston, and the lukewarmness of a large part of her population, was voted out of the Union by an irregularly called convention, whose final vote was 166 to 7.—In the documents put forth by the seceding states thus far no allusion is made to any cause of complaint against the northern states other than their interference with slavery. But it was not long before the secessionists took broader ground generally, and claimed to be acting in defence of state rights against the encroachments of the national government. Their position is thus stated by Mr. Stephens of Georgia in his "War between the States," published in 1867:

"Considerations connected with the legal status of the black race in the southern states, and the position of several of the northern states toward it, together with the known sentiments and principles of those just elected to the two highest offices of the federal government (Messrs. Lincoln and Hamlin) as to the powers of that government over this subject, and others which threatened, as was supposed, all their vital interests, prompted the southern states to withdraw from the Union, for the very reason that had induced them at first to enter into it; that is, for their own better protection and security. Those who had the control of the administration of the federal government denied this right to withdraw or secede. The war was inaugurated and waged by those at the head of the federal government against these states, or the people of these states, to prevent their withdrawal from the Union. On the part of these states, which had allied themselves in a common cause, it was maintained and carried on purely in defence of this great right, claimed by them, of state sovereignty and self-government, which they with their associates had achieved in their common struggle with Great Britain, under the declaration of 1776, and which in their judgment lay at the foundation of the whole structure of American free institutions."

—Thus in the space of three months after the presidential election seven states had renounced the Union and declared themselves sovereign and independent. Everywhere throughout these states the arsenals, custom houses, navy yards, and forts belonging to the United States were seized by the secessionists, with the exception of Fort Sumter, and Fort Pickens in Florida, which last was preserved by the energetic action of Lieut. Slemmer, its commander. The posts at the southern extremity of Florida also remained in the hands of the government. Those which fell into the hands of the secessionists were without garrisons, and were taken without bloodshed. The United States army at the beginning of the southern revolt was only 16,000 strong, and by orders from Mr. Floyd, the secretary of war, who was himself a party to the secession movement, had been dispersed in the remotest parts of the country. The largest force in one body was in Texas under the command of Gen. Twiggs, a Georgian by birth, who on Feb. 18 surrendered his whole command and all the posts and munitions of war to the Texans, for which on March 1 he was dismissed from the army by command of President Buchanan. Under Mr. Floyd's orders also an extensive transfer of arms from northern to southern arsenals had been made during 1860, 115,000 muskets being transferred by one order, and great quantities of cannon and ammunition by other orders. Congress assembled at Washington, Dec. 3, 1860, and President Buchanan's annual message was mainly devoted to the consideration of the secession movement. He recommended, as the most effectual mode of stopping the revolution, an amendment of the constitution embracing these three points: 1, an express recognition of the right of property in slaves in the states where it now exists or may hereafter exist; 2, the duty of protecting this right in all the common territories throughout their territorial existence, and until they shall be admitted as states into the Union with or without slavery as their constitutions may prescribe; 3, a like recognition of the right of the master to have his slave, who has escaped from one state to another, restored and delivered up to him, and of the validity of the fugitive slave law enacted for this purpose, together with a declaration that all state laws impairing or defeating this right are violations of the constitution and are consequently null and void. "Such an explanatory amendment would, it is believed, for ever terminate the existing dissensions, and restore peace and harmony among the states." This part of the message was referred in the senate to a committee of 13, who reported on Dec. 31 that they had not been able to agree upon any general plan of adjustment. Mr. Crittenden, a senator from Kentucky, introduced on Dec. 18 a plan of compromise, proposing to renew the Missouri line of 36° 30′; to prohibit slavery north and permit it south of that line; to admit new states with or without slavery as their constitutions might provide; to prohibit congress from abolishing slavery in the states, and in the District of Columbia so long as it exists in Virginia or Maryland; to permit free transmission of slaves by land or water in any state; to pay for fugitive slaves rescued after arrest; to ask the repeal of personal liberty laws in the states; these concessions to be submitted to the people as amendments to the constitution, and if adopted never to be changed. These were rejected, and the following resolutions, offered by Mr. Clark of New Hampshire, a republican senator, adopted: "That the provisions of the constitution are ample for the preservation of the Union, and the protection of all the material interests of the country; that it needs to be obeyed rather than amended; and that an extrication from the present dangers is to be looked for in strenuous efforts to preserve the peace, protect the public property, and enforce the laws, rather than in new guarantees for particular interests, compromises for particular

difficulties, or concessions to unreasonable demands. That all attempts to dissolve the present Union, or overthrow or abandon the present constitution, with the hope or expectation of constructing a new one, are dangerous, illusory, and destructive; that, in the opinion of the senate of the United States, no such reconstruction is practicable, and therefore to the maintenance of the existing union and constitution should be directed all the energies of all the departments of the government, and the efforts of all good citizens." These resolutions expressed substantially the position of the republicans in congress, who had become the majority in both houses by the resignation of the democratic senators and representatives from the seceded states. About the time that they were adopted, the legislature of Virginia passed resolutions recommending each of the states to appoint commissioners to a convention, the object of which should be "to adjust the present unhappy controversies." This proposition was approved by the president, and most of the loyal states promptly responded by appointing delegates. None appeared from the seceded states. The convention assembled at Washington, Feb. 4, 1861, and chose John Tyler of Virginia as chairman. After a session of three weeks the convention laid before congress a series of proposed amendments to the constitution, to the following effect: 1, prohibiting slavery north of lat. 36° 30′ in territories, but tolerating it in states, and forbidding all congressional or territorial legislation against slavery south of that line; 2, prohibiting any future acquisition of territory without the concurrence of a majority of senators both from slave and free states; 3, prohibiting congress from regulating, abolishing, or controlling slavery within any state, from interfering with or abolishing slavery in the District of Columbia or other places under exclusive federal jurisdiction, and from taxing slaves at a higher rate than land; 4, authorizing the states to enforce the rendition of fugitive slaves; 5, prohibiting the foreign slave trade. Another section provided for the payment from the United States treasury of the value of a fugitive slave whose rendition was prevented by mobs or by any violence or intimidation. The first, third, and fifth of these sections were to be permanent parts of the constitution, not to be abolished or amended without the consent of all the states. These propositions were rejected by congress, which had long had under consideration a variety of similar measures, all of which failed to secure a sufficient number of votes. The following amendment to the constitution was however recommended by the house by a two-thirds vote of 133 to 65: "No amendment shall be made to the constitution which will authorize or give to congress the power to abolish or interfere within any state with the domestic institutions thereof, including that of persons held to service or labor by the laws of said state." While these discussions were going on in congress, the cabinet of President Buchanan was disturbed and perplexed on the subject of reënforcing the forts in Charleston harbor, a measure opposed by Mr. Floyd, the secretary of war, and insisted upon by Gen. Cass, the secretary of state, who on Dec. 14 resigned his office in consequence of the president's refusal to order reënforcements. Four days before, Howell Cobb, the secretary of the treasury, had resigned and returned to his residence in Georgia, where he immediately took an active part in the secession movement. His place was filled by Philip F. Thomas of Maryland, while Mr. Black, the attorney general, was appointed temporary secretary of state. Shortly afterward, on the unexpected movement of Major Anderson from Fort Moultrie to Fort Sumter, and the president's refusal to comply with Mr. Floyd's demand for the entire withdrawal of the garrison from Charleston harbor, the latter resigned, and Joseph Holt, who had been appointed postmaster general on the death of Aaron V. Brown in 1859, was authorized to administer the affairs of the war department. Mr. Floyd's services to the cause of secession by supplying the southern states with arms from northern arsenals had been of the highest value, and he was soon made a brigadier general in the army of the seceded states. On Dec. 29 commissioners from South Carolina, who had recently arrived in Washington, endeavored to open negotiations with the president for the surrender to South Carolina of the United States forts and other national property within her borders. The president declined to receive them as commissioners, or to surrender or evacuate Fort Sumter, and permitted his cabinet to make an attempt to send reënforcements to Major Anderson by the steamer Star of the West, which left New York Jan. 5, 1861, and arrived off Charleston on the morning of the 9th; but she was fired at from batteries manned by the forces of the state, and compelled to retire without effecting her purpose. This led to the immediate resignation of Jacob Thompson, secretary of the interior, and his return to Mississippi, from the revolutionary government of which he had while still in office received and acted upon a commission to visit and promote the secession of North Carolina. A few days later Mr. Thomas, also disapproving of the attempt to reënforce Fort Sumter, withdrew from the treasury department, and was succeeded by John A. Dix of New York, who was in favor of vigorous measures for maintaining the authority of the government. The legislatures of New York, Ohio, and Massachusetts at this time offered the whole military power of those states to the president, while the South Carolina legislature declared that any attempt to reënforce Fort Sumter would be an act of war. No further attempt, however, was made at reënforcement during the administration of President Buchanan, which came to an end March 4, 1861. On that day Mr. Lincoln was inaugurated at

Washington. In his inaugural address the president began by declaring that the accession of a republican administration afforded no ground to the southern states for apprehending any invasion of their rights. He said: "I have no purpose, directly or indirectly, to interfere with the institution of slavery in the states where it exists. I believe that I have no lawful right to do so, and I have no inclination to do so. Those who nominated and elected me knew that I had made this and many similar declarations, and had never recanted them." He proceeded to argue that no state upon its own mere motion can lawfully go out of the Union; that resolves and ordinances to that effect are legally void; and that acts of violence within any state or states against the authority of the United States are insurrectionary or revolutionary according to circumstances. "I therefore consider that, in view of the constitution and the laws, the Union is unbroken; and to the extent of my ability I shall take care, as the constitution itself expressly enjoins upon me, that the laws of the Union be faithfully executed in all the states." President Lincoln appointed as his cabinet William H. Seward, secretary of state; Salmon P. Chase, of the treasury; Simon Cameron, of war; Gideon Welles, of the navy; Caleb B. Smith, of the interior; Edward Bates, attorney general; and Montgomery Blair, postmaster general. The last two were from the slave states of Missouri and Maryland. The executive government of the United States was thus transferred from the hands of a party which had held it since the beginning of the century, with two or three brief intervals, during which period of 60 years southern men had occupied the presidential chair for more than two thirds of the time, while the northern men who attained to that high office, with the single exception of John Quincy Adams, were "northern men with southern principles." It was a great and striking change of dynasty, and was naturally followed by profound convulsions. — Meantime the seceded states had been making vigorous efforts to organize and sustain a general government for themselves. On Feb. 4, 1861, a congress composed of delegates from South Carolina, Georgia, Florida, Alabama, Mississippi, and Louisiana met at Montgomery, Ala., and were joined not long afterward by delegates from Texas. Howell Cobb of Georgia, ex-secretary of the treasury of the United States, was elected chairman. A constitution for the provisional government of the "Confederate States of America" was adopted, Feb. 8, which generally resembled that of the United States, but was superseded by a permanent constitution adopted unanimously March 11. This constitution adopted in nearly all its parts the precise language, and followed in its articles and sections the arrangement of the constitution of the United States. The main particulars in which it differed from that instrument were these: In the preamble the words "each state acting in its sovereign and independent character" were inserted to include the doctrine of state sovereignty, and to exclude the argument drawn from the preamble of the old constitution that it had been made by the people of the states collectively, and not by the states themselves. The official term of the president and vice president was extended to six years, and the president disqualified for reëlection. The protective policy was prohibited by the declaration that no duties or taxes on importations from foreign nations should be laid to promote or foster any branch of industry. Export duties were allowed to be levied with the concurrence of two thirds of both houses of congress. The impeachment of any judicial or other federal officer, resident and acting solely within the limits of any state, was allowed by a vote of two thirds of both branches of the legislature thereof, as well as by the house of representatives of congress; but the senate of the Confederate States was to have the sole power to try all such impeachments. No general appropriation of money was allowed unless asked for and estimated by some one of the heads of departments, except by a two-thirds vote in both branches of congress. The object of this was to make each administration responsible as far as possible for the public expenditures. All extra pay or extra allowance to any public contractor, agent, or servant was prohibited, as well as all bounties. Internal improvements by congress were prohibited. The power of the president to remove from office was restricted to removals for special cause, which must be reported to the senate with the reasons therefor, except in the case of the principal officer in each of the executive departments and all persons connected with the diplomatic service. The right of any citizen of one state to pass through or sojourn in another with his slaves was expressly guaranteed. In adjusting the basis of representation and direct taxation, "three fifths of all slaves" are enumerated, instead of three fifths of "other persons," as in the constitution of the United States. The clause relating to fugitives from service or labor in the old constitution was enlarged so as expressly to include slaves, in order to preclude that interpretation which limited its meaning to apprentices and other persons legally bound for a term of years. The African slave trade was prohibited. Slavery in the territories was to be "recognized and protected by congress and by the territorial government." And finally it was provided that "congress may by law grant to the principal officer in each of the executive departments a seat upon the floor of either house, with the privilege of discussing any measures appertaining to his department." Some of these changes were improvements on the constitution of the United States, which the experience of 70 years had shown to be desirable. Others, especially those relating to

protection, bounties, and internal improvements, referred to controverted points in American politics on which public opinion is yet undecided; while those relating to slaves were intended to cover the whole ground of quarrel on which the Confederate States had seceded from the Union. Before the adoption of the permanent constitution, in fact on the day following the adoption of the provisional constitution, that is, on Feb. 9, an election for president and vice president was held by congress, voting by states as that constitution directed. All the states present (the delegates from Texas not having yet arrived) voted for Jefferson Davis of Mississippi for president, and Alexander H. Stephens of Georgia for vice president. Mr. Davis was not a member of congress, and was absent in Mississippi. It was understood that he aspired to the command of the army and did not wish to be president. He however accepted the office, arrived at Montgomery Feb. 16, and was inaugurated on the 18th. Mr. Stephens, who was a member of congress, had been sworn into office as vice president on the 10th. A few days later Mr. Davis appointed his cabinet, as follows: secretary of state, Robert Toombs of Georgia; secretary of the treasury, Charles G. Memminger of South Carolina; secretary of war, Leroy P. Walker of Alabama; secretary of the navy, Stephen R. Mallory of Florida; postmaster general, John H. Reagan of Texas; attorney general, Judah P. Benjamin of Louisiana. All of these except Memminger and Walker had been senators or representatives in the congress of the United States. The principles upon which the new government was founded were very clearly expounded by its vice president, Mr. Stephens, in a speech made by him at Savannah, March 21, 1861, as follows:

"The new constitution has put at rest for ever all the agitating questions relating to our peculiar institutions—African slavery as it exists among us—the proper status of the negro in our form of civilization. This was the immediate cause of the late rupture and present revolution. Jefferson, in his forecast, had anticipated this as the rock upon which the old Union would split. The prevailing ideas entertained by him, and most of the leading statesmen at the time of the formation of the old constitution, were that the enslavement of the African was in violation of the laws of nature; that it was wrong in principle, socially, morally, and politically. Our new government is founded upon exactly the opposite ideas; its foundations are laid, its corner stone rests upon the great truth that the negro is not equal to the white man; that slavery, subordination to the superior race, is his natural and normal condition. This, our new government, is the first in the history of the world based upon this great physical, philosophical, and moral truth. It is the first government ever instituted upon principles in strict conformity to nature, and the ordination of Providence, in furnishing the materials of human society. Many governments have been founded upon the principle of enslaving certain classes; but the classes thus enslaved were of the same race, and enslaved in violation of the laws of nature. Our system commits no such violation of nature's laws. The negro by nature, or by the curse against Canaan, is fitted for that condition which he occupies in our system. The architect, in the construction of buildings, lays the foundation with the proper material, the granite; then comes the brick or the marble. The substratum of our society is made of the material fitted by nature for it, and by experience we know that it is best, not only for the superior but for the inferior race, that it should be so. It is, indeed, in conformity with the Creator. It is not for us to inquire into the wisdom of his ordinances or to question them. For his own purposes he has made one race to differ from another as he has made 'one star to differ from another in glory.' The great objects of humanity are best attained when conformed to his laws and decrees, in the formation of governments as well as in all things else. Our confederacy is founded upon principles in strict conformity with these laws. This stone, which was rejected by the first builders, 'is become the chief stone of the corner' in our new edifice."

—The two governments, that of Washington and that of Montgomery, alike in form and organization, but radically different in principles, thus stood face to face in the month of March, 1861. Between them stood the border states, as they were called, the slave states of Arkansas, Missouri, Tennessee, Kentucky, North Carolina, Virginia, Maryland, and Delaware, which naturally sympathized with the slave states south of them, but in which the Union sentiment was still strong, and the sense of danger from their exposed position was calculated to impress upon the prudent part of their population the necessity of caution and moderation. Both sides were anxious to gain their support, and from the beginning of the secession movement their capitals had swarmed with ardent emissaries, official and volunteer, imploring them to join their brethren of the south. Their population and resources made their accession to either side of great importance; but to the south their assistance was essential in case of war. Their population was between 6,000,000 and 7,000,000, a large majority of whom were whites, while the whole population of the seven seceded states was less than 5,000,000, of whom nearly one half were slaves, of no value for military purposes. On the other hand, the free states, the states certain to uphold the Washington government, numbered 20,000,000 inhabitants, and were incomparably richer in money and credit, and in military and especially naval resources, than the south. They were in fact nearly twice as strong in numbers as all the slave states together, and in wealth and resources were even more formidable than in numbers. But their superiority in these respects was weakened by party divisions. The republican party by its success in the presidential election had obtained control of the national government, and was also in possession of all the free-state governments except that of Oregon. But it found itself everywhere confronted by a democratic minority, little inferior to itself in numbers, exasperated by a defeat at the polls which had wrested from it the control of a continent and the revenues of an empire, and still strongly affected, on the one hand, by the animosities engendered by its long and bitter controversy with the republicans, and on the other by its natural sympathy with the southern democracy, with whom it had been for many years in perfect political alliance and agreement, and from whom it now differed on no point of principle or policy except that of secession. The secession leaders counted largely on the support of the northern democrats, and repeatedly declared that they had positive as-

surances of assistance from them in case the government attempted to assert its authority by force of arms. On this point Horace Greeley in his "American Conflict" says: "The great mails, during the last few weeks of 1860, sped southward, burdened with letters of sympathy and encouragement to the engineers of secession, stimulating if not counselling them to go forward in their predetermined course." In the south, on the contrary, all party lines were obliterated as soon as the states seceded. So confident were the people of their own prowess, and so little acquainted with the spirit and resources of the free states, that there was an almost universal conviction among them that the confederacy was already an accomplished fact, and that the union with the north was for ever ended. A strong party in the south had adhered to the Union until their states seceded, and then, considering the matter practically settled, had transferred their allegiance to the new government.—Meantime a crisis was rapidly approaching. The key of the situation was Fort Sumter. The south regarded its continued occupation by a national garrison as an encroachment upon their sovereignty, and demanded that the intruders should be expelled. The north regarded it as the symbol of the Union on an otherwise rebellious and hostile shore, and were ready to spring to arms to resent an attack upon it. It was known to both sides that the garrison was very small, consisting of less than a company of soldiers, and a few laborers and musicians, and that they were very short of provisions and of ammunition. It was known also that the South Carolinians had been for several months erecting batteries of heavy guns in the most favorable positions for bombarding the fort, and that they had stationed in these batteries some 7,000 troops commanded by Gen. Beauregard, an experienced engineer, who had been an officer of the United States army. About a week after President Lincoln's inauguration a letter was sent to Mr. Seward, secretary of state, signed by John Forsyth and Martin J. Crawford, who claimed to be commissioners from the confederate government, authorized to make overtures to the government of the United States for the opening of negotiations. Mr. Seward replied, by a memorandum dated March 15, that he could not in any way admit that "the so-called Confederate States constitute a foreign power, with whom diplomatic relations ought to be established;" and both he and the president declined official intercourse with the commissioners, who remained for some weeks in Washington, and made other attempts at negotiation, with especial reference to Fort Sumter, of which they demanded the peaceful evacuation, or at least a pledge that it should not be relieved or reenforced. The president declined to give any such pledge, and at a cabinet meeting held March 21 it was determined that a fleet should be sent to the rescue of Major Anderson. A squadron, hastily equipped, and carrying supplies and a body of soldiers, was despatched from New York and other northern ports on April 6 and 7, and on the 8th formal notice was given to the governor of South Carolina that the fleet was on its way to relieve the fort. Gen. Beauregard immediately telegraphed this information to Montgomery, and on the 10th received orders from the confederate secretary of war to demand the immediate surrender of the fort, and in case of refusal to reduce it. The demand was made on the 11th, and being refused, a bombardment began on the 12th, which resulted in the surrender of the fort on the 13th, the fleet, which appeared off Charleston harbor on the 12th, not finding it practicable to assist the garrison. (See SUMTER, FORT.) This event, the details of which as they occurred were transmitted by telegraph from Charleston to all parts of the country, created the greatest excitement both at the north and the south. Charleston was wild with exultation. The bells were rung, guns were fired, great crowds assembled, and the governor made a speech in which he said: "We have humbled the flag of the United States. We have defeated their twenty millions; we have brought down in humility the flag that has triumphed for 70 years; to-day, on this 13th day of April, it has been humbled, and humbled before the glorious little state of South Carolina." At Montgomery there was equal exultation. An immense crowd assembled on the evening of April 12, and was addressed by Mr. Walker, the confederate secretary of war, who said: "No man can tell where the war this day commenced will end, but I will prophesy that the flag which now flaunts the breeze here will float over the dome of the capitol at Washington before the first of May. Let them try southern chivalry and test the extent of southern resources, and it may float eventually over Faneuil hall itself." At Washington the effect of the news was to call forth the following proclamation from President Lincoln:

"Whereas the laws of the United States have been for some time past and are now opposed, and the execution thereof obstructed, in the states of South Carolina, Georgia, Alabama, Florida, Mississippi, Louisiana, and Texas, by combinations too powerful to be suppressed by the ordinary course of judicial proceedings, or by the powers vested in the marshals by law: Now, therefore, I, Abraham Lincoln, president of the United States, in virtue of the power in me vested by the constitution and the laws, have thought fit to call forth, and hereby do call forth, the militia of the several states of the Union, to the aggregate number of 75,000, in order to suppress said combinations, and to cause the laws to be duly executed. The details for this object will be immediately communicated to the state authorities through the war department. I appeal to all loyal citizens to favor, facilitate, and aid this effort to maintain the honor, the integrity, and the existence of our national union, and the perpetuity of popular government, and to redress wrongs already long enough endured. I deem it proper to say that the first service assigned to the forces called forth will probably be to repossess the forts, places, and property which have been seized from the Union; and in every event the utmost care will be observed, consistently with the objects aforesaid, to avoid any devastation, any destruction of or interference with property, or any disturbance of peaceful citizens in any part of the country. And I hereby command the persons composing the combinations aforesaid to disperse and retire peaceably to their respective

abodes within twenty days from this date. Deeming that the present condition of public affairs presents an extraordinary occasion, I do hereby, in virtue of the power in me vested by the constitution, convene both houses of congress. Senators and representatives are therefore summoned to assemble at their respective chambers, at 12 o'clock, noon, on Thursday, the fourth day of July next, then and there to consider and determine such measures as, in their wisdom, the public interest and safety may seem to demand."

On this call to arms the north, which had been for months patiently though anxiously waiting for the government to act, rose almost as one man. Great meetings were held in all the large cities, in which men of all parties united. The governors of all the northern states responded promptly to the demand for troops. Massachusetts was the first in the field. On the day after the proclamation appeared, four regiments of volunteers, twice the number called for by the secretary of war, mustered with full ranks on Boston common, and three days later one of these regiments, the 6th, was 500 miles on its march to Washington, and was fighting its way through Baltimore on the 19th of April, the anniversary of Lexington and Concord, having been attacked in the streets by a mob of secessionists, whom it repulsed, not without considerable bloodshed on both sides. Pennsylvania was almost equally prompt, and her legislature sanctioned a loan of $3,000,000, and organized a reserve corps besides her quota. New York, called upon for 17,000 men for three months, responded by raising 30,000 for two years, and voted a war loan of $3,000,000. Rhode Island sent her quota at once, with her governor at its head. The other free states did likewise, and men and money were contributed to an extent far beyond what was demanded by the government. On the other hand, the governors of the border states replied to the requisition for troops in a defiant manner, and positively refused to furnish any. Those states, in fact, were as much excited by the fight at Sumter as any part of the nation, and there is no doubt that the attack on the fort was mainly prompted by a desire on the part of the confederate leaders to precipitate the border states into secession. Secessionists from all those states had long been urging upon the leaders at Montgomery and at Charleston the necessity of doing something decisive. "Sprinkle blood in the faces of the people of Alabama," said Mr. Gilchrist, a member of congress from that state, "or they will be back in the Union in less than ten days." "Strike a blow," said Roger A. Pryor, ex-congressman from Virginia, addressing the citizens of Charleston on the eve of the attack on Fort Sumter, "and the moment that blood is shed Virginia will make common cause with her sisters of the south." These persons knew well the spirit of their states. As late as April 4 the Virginia convention, by the decisive vote of 89 to 45, had refused to pass an ordinance of secession. On the 17th, four days after the surrender of Fort Sumter, the same convention in secret session, by a vote of 88 to 55, decreed the separation of Virginia from the Union, and her adhesion to the southern confederacy. A day or two later her military forces, energetically led, were in possession of the great navy yard at Norfolk, and of the United States arsenal at Harper's Ferry, neither of which was sufficiently garrisoned, though they contained millions of dollars worth of arms and ammunition, of incalculable value to the insurgents. At Norfolk alone they obtained 2,000 cannon and the steam frigate Merrimack, one of the finest in the navy. West Virginia, including more than a third of the area of the state and nearly a fourth of its white population, with very few slaves, refused to secede from the Union, but on the contrary seceded from Virginia. A convention of delegates from 40 counties met at Wheeling June 11, and formed a provisional government of men loyal to the Union. Five months later (Nov. 26) another convention assembled at Wheeling, framed a constitution for a new state, which was admitted by congress in December, 1862, and comprises 50 counties and nearly half a million of inhabitants. Tennessee speedily followed Virginia, and seceded May 6, but not without strong opposition from the eastern part of the state, where there were very few slaveholders, and where the Unionists were ably led by William G. Brownlow, Andrew Johnson, Horace Maynard, and other conspicuous citizens. The right of secession from the state, however, was denied them, and for a year or two they were severely persecuted for their fidelity to the Union, and were kept in subjection to the confederacy by military force, until relieved by the advance and victories of the Union armies. Arkansas seceded May 6, and North Carolina May 20. The excitement created by the attack on Fort Sumter had thus carried four states out of the Union. No more states formally seceded. Of the 15 slave states, 11 had now withdrawn. Four, Missouri, Kentucky, Maryland, and Delaware, maintained their constitutional compact, though great efforts were made to induce them to join the south. Missouri and Kentucky were indeed claimed by the confederacy, and were admitted to representation in the confederate congress; and Maryland furnished many soldiers to the confederate army. Missouri was in fact saved from actual secession only by a sharp and bloody struggle between the confederate party led by Claiborne F. Jackson, governor of the state, and Sterling Price, an ex-governor, and the Union party, headed by Francis P. Blair and B. Gratz Brown, who had also the support of the garrison of the United States arsenal at St. Louis, consisting of several hundred troops commanded by Capt. Nathaniel P. Lyon.

—Immediately after the occurrences at Fort Sumter Jefferson Davis summoned the confederate congress to meet in Montgomery on April 29. In a session of three weeks measures were taken to raise money, to organize an army, and to issue letters of marque to privateers. A loan

was authorized to the amount of $50,000,000, in addition to a previous loan of $15,000,000. These sums were to be raised by the sale of confederate bonds, redeemable at the expiration of 20 years, with interest at 8 per cent. per annum. The president was authorized to accept the services of 100,000 volunteers, to serve during the war. There being no means to create a regular navy, 15 or 20 small vessels were commissioned as privateers, and in the course of the summer a considerable number of prizes were taken or destroyed. On May 21 the congress adjourned to meet again on July 20 in Richmond, Va., which had been agreed upon as the confederate capital, and continued to be such until the fall of the confederacy. Nearly all the available troops of the confederacy were concentrated in Virginia, along a line extending from Harper's Ferry to Norfolk. Their strongest position was at Manassas Junction, on the direct road from Washington to Richmond, where Beauregard was in command with a force of 20,000 men. The entire force in Virginia, including militia, was about 60,000, and was under the command of Gen. Joseph E. Johnston, formerly of the United States army. Among the other officers who soon became distinguished were Robert E. Lee, T. J. Jackson, commonly called "Stonewall" Jackson, E. Kirby Smith, James Longstreet, and A. P. Hill. To oppose this formidable force the national government concentrated an army at Washington under the nominal command of the aged and infirm Gen. Winfield Scott. This force mainly occupied the Virginia side of the Potomac opposite the city. The United States government at this time was very much embarrassed by want of arms. The loss of Harper's Ferry left it with no arsenal of construction but that of Springfield, Mass. It had men in abundance, but its forces lacked not only arms but discipline. Many of its best officers had resigned from the army to enter the southern service, and its troops were raw levies compared with those of the south, who had been in training for several months longer. Every exertion was made to remedy these deficiencies. Agents were sent abroad to purchase arms, and the private manufactories in the northern states were worked to their utmost capacity. On April 19 the president proclaimed a blockade of all ports in the seceding states; and as the existing navy was not sufficient for the purpose, the navy department bought or chartered hundreds of merchant vessels and fitted them for war. On May 3 the president issued a proclamation calling for 42,000 volunteers to serve for three years, and also for 22,000 men to be added to the regular army and 18,000 to the navy. Persons of known or suspected treasonable conduct were arrested by order of the secretary of state, and confined in some of the national forts, and military officers were instructed to disregard all writs of habeas corpus issued for the release of such prisoners. These measures of the president were without sanction of law, but congress at its next session formally approved them, and declared them legalized and valid on the ground that they were war measures demanded by the exigency of circumstances and essential to the safety of the republic.—We have now traced the origin and progress of secession from its commencement in November, 1860, to its culmination in May, 1861, when it resulted in one of the greatest wars recorded in the annals of mankind. The movement had been singularly rapid, because the material and the motives for it had been long accumulating, and it was controlled by able and experienced politicians, who perfectly understood the temper and the feelings of the population with which they had to deal, and skilfully worked upon their ambition, their prejudices, their hopes, and their fears. On the confederate side of this great struggle were enlisted states containing five or six millions of whites, more than a million of them capable of bearing arms, brave, high-spirited, and warlike, accustomed to the use of weapons from childhood, confident of their own superior prowess and despising that of their opponents, and confident also of the rectitude of their cause and of the soundness of the principle of state sovereignty, for which mainly they had appealed to the gage of battle. On the other hand was a nation of 20,000,000, equally brave, though less accustomed to the use of arms, preferring peace to war, and if possible even more confident of the justice of their cause, and prepared to make any sacrifices for the salvation of the Union and the preservation of their country from the fate of the Spanish American republics. Both sides were of the same lineage, spoke the same language, professed the same religion, and, with the sole exception of slavery, differed little in manners, morals, general culture, and civilization. In the south agriculture was the predominant pursuit, and cotton its most valuable product. In the north agriculture was more diversified, and in addition to it a vast amount of manufacturing and commercial industry was carried on. The north was richer, and by its marine could command the sea, while its foreign trade supplied it with whatever arms and munitions of war it failed to produce within its own limits. The south at first was largely infatuated with the notion that the "northerners would not fight, and that if they did fight every southerner was a match for five of them." A delusion even more general in the south was expressed by the current phrase, "Cotton is king;" by which was meant that the cotton of the south was an essential element of the prosperity of the north and of the manufacturing countries of Europe; and that if the southern supply of the material was cut off, intolerable suffering would result, especially in England and France, which would compel the governments of those countries to interfere in behalf of the south. This delusion was soon dispelled by the logic of events. Though the price of

cotton advanced greatly all over the world in consequence of the blockade and of the diminished production in the south, this very advance in price stimulated its production in other countries, and India, Egypt, and South America supplied the market with large quantities. Europe was not driven to interfere in our civil strife, and her greatest powers, though with the exception of Russia they evidently hoped the south would succeed, did not dare openly to take her side, nor to give any but indirect and furtive encouragement to her agents, who made strenuous efforts to get foreign recognition and assistance for the confederacy. Nor did the south receive that assistance from the northern democrats on which she had counted so confidently. The great body of the party rallied round the flag of the Union, and volunteered in vast numbers for the defence of the nation, while many prominent democratic politicians attained the highest ranks in the army. Only a very small number of northern democrats joined the confederate forces, and the northern opponents of the government made no more formidable demonstration than a riot in New York, which broke out on occasion of a draft for the army, during the absence of military forces from the city, and was easily quelled when the soldiers returned. Politically the gravest demonstration made by the opposition was at their national convention which met at Chicago Aug. 29, 1864, and resolved that "four years of failure to restore the Union by the experiment of war" required that "immediate efforts be made for a cessation of hostilities." They offset this, however, by nominating as their candidate for president a distinguished commander of the Union army, Gen. George B. McClellan. The defeat of the democrats in the presidential election of 1864, and the reëlection of President Lincoln, followed by brilliant successes of the Union armies under Grant and Sherman, deprived the confederates of their last hope, and made it apparent to all the world that the great conflict was drawing to its close. The Confederate States, stripped of men and money, their resources exhausted, their finances ruined, and the fairest portions of their territory ravaged by fire and sword, could no longer continue the unequal struggle, and presently collapsed, the people quietly submitting to their fate.—The main military events of the war were the battle of Bull Run, July, 1861; the capture of Fort Donelson, February, 1862; McClellan's campaign on the peninsula of Virginia, April to July, 1862; the battle of Shiloh, April, 1862; the capture of New Orleans, April, 1862; the second battle of Bull Run, August, 1862; the battle of Antietam, September, 1862; the battle of Fredericksburg, December, 1862; the battle of Stone river, December, 1862; the battle of Chancellorsville, May, 1863; the battle of Gettysburg, July, 1863; the capture of Vicksburg, July, 1863; the battle of Chickamauga, September, 1863; the battle of Chattanooga, November, 1863; Banks's Red river campaign, March and April, 1864; the battles in the Wilderness, at Spottsylvania Court House, and in southern Virginia, May and June, 1864; Sherman's Atlanta campaign, May to September, 1864; the battle near Nashville, December, 1864; Sherman's march to the sea, November and December, 1864; the siege of Petersburg, June, 1864, to April, 1865; Sherman's march through Georgia and the Carolinas, January to April, 1865; and finally the surrender of Lee's army in Virginia and of Johnston's in North Carolina, in April, 1865. The adjutant general of the confederate army, in a statement made since the close of hostilities, estimated the entire available confederate force capable of active service in the field at 600,000 men. Of this number not more than 400,000 were enrolled at any one time, and the Confederate States never had in the field at once more than 200,000. When the war ended the southern army was reduced to less than one half of this number. Scanty as these forces were compared with the northern armies, they made a most resolute and gallant defence, especially in Virginia under the command of Gen. R. E. Lee. Nor did they fail in any part of the war to exhibit manly courage, patient endurance of privations, and a steadfast adherence to what they considered the cause of their country. The last great military act of the war, the surrender of Johnston to Sherman, was followed on May 14 by that of Gen. Taylor with all the remaining confederate forces east of the Mississippi, and on the 26th of the same month by that of Gen. Kirby Smith with all his command west of the Mississippi, both to Gen. Canby. With these surrenders ended all military opposition to the government at Washington. The flag of the United States was lowered at Fort Sumter by Major Anderson, April 14, 1861. On the fourth anniversary of that event, April 14, 1865, the same flag was raised on Fort Sumter by the same Anderson, now promoted to the rank of major general. On April 3, when it became known in Richmond that Lee was defeated and that the city must be evacuated, Jefferson Davis fled southward in hopes of escaping by sea. He had made his way to southern Georgia when he was arrested near Irwinville by a party of Union cavalry sent in pursuit of him. He was taken to Fortress Monroe and kept for a considerable time in confinement, but was finally liberated on bail. For the history of the civil war, see the articles on the various battles under their own names, the notices of the prominent statesmen and generals on both sides, and UNITED STATES.—Nothing like an adequate collection of the official documents relating to the civil war has ever been attempted. "The Rebellion Record" (9 vols. 8vo, 1861–'5), edited by Frank Moore, contains many documents and reports not otherwise accessible. The lack of published official reports on the operations of the Union

armies is in a good degree supplied by the "Report of the Joint Committee of Congress on the Conduct of the War." This embraces the sworn testimony of a very large proportion of the officers who bore a prominent part in military operations. The confederate "Report of the Operations of the Army of Northern Virginia" (3 vols. 8vo), embracing the period from the beginning of the seven days' battles down to the battle of Chancellorsville, is remarkably full and complete. Besides the general report of Lee, and detailed reports from each division commander, there are nearly 400 from subordinate officers. For all other periods the accessible confederate reports are nearly worthless. Of special reports, that of McClellan on the "Organization and Campaigns of the Army of the Potomac," and that of Pope describing the operations of the army of Virginia, are valuable. A monograph by Hotchkiss and Allan, confederate engineers, relating to the battle of Chancellorsville, is of great value on account of its accurate military maps of the region of the "Wilderness." Among the general histories of the war are to be noted those of Horace Greeley, "The American Conflict" (2 vols. 8vo, 1866); John W. Draper, "History of the American Civil War" (3 vols. 8vo, 1868–'70); A. H. Guernsey and H. M. Alden, "Harper's Pictorial History of the Great Rebellion" (4to); Edward A. Pollard, "The Lost Cause: a new Southern History of the War of the Confederates" (1866); Alexander H. Stephens, "The War between the States" (2 vols. 8vo, 1868–'70); and William Swinton, "Campaigns of the Army of the Potomac" (1866), and "The Twelve Decisive Battles of the War" (1871).

CONFESSION, Auricular, in the Greek and Roman Catholic churches, the acknowledgment of sins to an authorized priest, made with the view of obtaining absolution. According to the doctrine of the Catholic church, confession is obligatory on all who have committed mortal sin after baptism. The confession of venial sins is recommended as salutary, and generally practised by the more devout. Catholic theology teaches that the requisites to a good confession are, that it should be entire, conjoined with sincere contrition and a firm purpose of amendment, and followed by acts of penance or satisfaction to the justice of God. By a canon of the fourth council of the Lateran (1215), which is a formal reënactment of a general law previously existing, all who are conscious of mortal sin are bound to confess at least once a year. Those who are in danger of death, or about to expose themselves to the danger of death, are similarly bound. Much more frequent confession is recommended, and very generally practised. No priest can hear confessions or give a valid absolution, except to a person in danger of death, unless he has jurisdiction from the ordinary of the diocese, and such jurisdiction is more or less limited by reservations to the bishop or the sovereign pontiff. A priest is forbidden, under the severest ecclesiastical penalties, to divulge anything disclosed under the seal of confession, even when questioned in a court of justice; and he may not even speak to the penitent of the sins he has confessed, outside of the confessional, without his express permission. According to Catholic theology, auricular or private confession has been practised from the time of the apostles, although there has been a change of discipline since the early ages, adopted by the church on account of a change of circumstances. Public confession was practised in these early times, and very severe and long penances were imposed on those who were guilty of grievous public sins. After the fervor of the first ages had diminished, and sins had become more frequent, these public confessions were an occasion of scandal, and the severe penitential canons were injurious rather than profitable. Nectarius, patriarch of Constantinople, abolished the office of public penitentiary in his cathedral at the close of the 4th century, and from that time public confession fell into disuse in the East. In the West it was disused after the 7th century. Public confession was never required except when the sins were public, and the public confession of secret sins was only counselled in certain cases, as a penance. Many sins, especially under the severe laws of Christian emperors, could not have been publicly confessed without exposing the criminal to the penalty of death; as for instance, murder, the adultery of a woman, and that of a man with a woman of noble birth. Secret sins were first privately confessed to a priest, and if the penitent desired to confess them publicly, the confessor judged whether this were expedient. Auricular confession is recommended by some divines in the Anglican and Lutheran churches as a salutary practice, and even by the prayer book of the church of England.—For information on private confession in the church of England, see *Visitatio Infirmorum*, by W. H. Cope and H. Stretton (London, 1850). For the Catholic literature and theology on confession, see Renaudot's *Perpétuité de la foi sur les sacrements.*

CONFIRMATION, in some churches a sacrament, in others a rite supplemental to baptism. Its history is traced to the apostles (Acts viii. and xix., Eph. xix., &c.), who were wont to lay hands on neophytes and to pray in order that they might receive the Holy Ghost. In the succeeding ages, to "the imposition of hands" is found added the "chrismation," or anointing of the forehead with chrism. The entire rite came to be designated as "the sacrament of chrism," "the receiving of the cross," the "sign of the Lord," "the seal," and "the signing or sealing," *consignatio.* Hence the recipients were called *consignati*, "signed;" and the place in or near the baptistery, set apart for confirmation, was known as the *consignatorium.* In the ancient sacramentary of Pope Gelasius (492), confirmation is ordered

to be administered in this form: "The sign of Christ unto life eternal." The earliest use of the term itself occurs in the "Apostolic Constitutions" (B. III., c. 17), where "the chrism" is called *confirmatio confessionis*, a sanction of the baptismal profession of faith.—In ancient times bishops administered confirmation immediately after baptism; both priests and bishops do so still in the Greek church; and in the Latin church bishops may and sometimes do confer both sacraments at once, even in the case of infants. Priests can confirm only by delegation of the pope, in foreign missions, and during persecution, &c.—In Germany, where the reformation had discountenanced confirmation altogether, its use was restored by Spener, and the Lutheran and Reformed churches now practise it as a renewal of the baptismal covenant. The age for this is from 13 to 16. The church of England calls it "a solemn, ancient, and laudable custom, continued from the apostolic times," and fixes for the rite the age of from 16 to 18. This meets the wishes of the low church, who reject the sacramental virtue of confirmation; but high church men urge a much earlier age.

CONFLAGRATION (Lat. *conflagratio*, a burning together), the destruction by fire of a considerable part of a large town or city. The term is also applied to fires which overrun a large extent of prairie or forest; such as that in October, 1871, which swept over a great portion of the peninsula between Lakes Huron and Michigan. By this conflagration it is estimated that 4,000,000,000 feet of timber was destroyed, and thriving towns, farm and school houses, churches, stock, and crops were consumed; and nearly 3,000 families, or about 18,000 persons, were rendered homeless. —Conflagrations have been sometimes the consequence of earthquakes and volcanic eruptions, but oftener of accident; and in early times very frequently cities were wantonly burned by conquerors. The final destruction of Nineveh was doubtless accomplished by fire; but whether this took place at the time of its capture is uncertain. The fact of the destruction by conflagration is attested by the heaps of charcoal and other signs of devouring fire which are still found among the ruins of all the royal palaces at Nimrud, Koyunjik, and Khorsabad. Fire had also an important part in the ruin of Babylon, as is shown by the vivid account of Jeremiah, whether it is to be regarded as history or prophecy: "The mighty men of Babylon have forborne to fight; they have remained in their holds; their might has failed; they became as women: they have burned her dwelling places; the passages are stopped, and the seeds they have burned with fire; the broad walls shall be utterly broken; and her high gates shall be burned with fire." All which seems to imply that the city was dismantled, and that fire was brought in to destroy the palaces and fortifications; but the brick walls and ordinary houses were left, and their almost entire disappearance is owing to time and the elements. Ctesiphon and Seleucia, cities built in a great measure from the ruins of Babylon, were repeatedly sacked and burned. Seleucia, at the time of its destruction by the Romans under Lucius Verus, about A. D. 165, is said to have contained 500,000 inhabitants, of whom 300,000 were massacred. So complete was the destruction that 40 years later the site of the city was a marsh, filled with wild game. Bagdad, partly built from the ruins of Seleucia, famous during the middle ages, and yet the most considerable city of Mesopotamia, was in 1258 captured, sacked, and partly burned by Hulaku, the grandson of Genghis Khan; and again by the Turks in 1638, when a large part of the population was put to death, and a great part of the city burned. Damascus was captured and burned by the Assyrians under Tiglath-Pileser; the capture and sack is among the subjects depicted on the extant Assyrian monuments. The story of the Trojan war is perhaps partly mythical; but this much at least appears clearly historical: About 1184 B. C. the city of Ilium, in the Troad, was besieged, finally taken by the Greeks, and destroyed, fire being largely used in the destruction. The cities of the ancient Egyptians had little wood in their construction, and contained little combustible material; and their destruction appears not to have been accomplished by conflagration. Alexandria, founded by Alexander the Great in 332 B. C., was a Greek city rather than Egyptian, and was several times the scene of great fires; as in its blockade in the time of Julius Cæsar, and in the 4th century, when the temple of the Serapeum was destroyed by Christian fanatics. Tyre was captured by Alexander the Great in 332 B. C., after a long siege; and even after the Macedonians entered the city an obstinate resistance was kept up from the roofs of the houses. Irritated by this, the conquerors set fire to the city, massacred 8,000 of the inhabitants, crucified 2,000, and sold 30,000 more into slavery. During the long period between Nebuchadnezzar and the final Turkish domination, Jerusalem was for nearly a score of times in a great measure destroyed by conflagration. It was taken by Nebuchadnezzar in 586 B. C., when the temple and all the buildings were burned, and the walls completely demolished. After half a century or more a new city grew up on the site of the old one; this was mostly destroyed by fire under Antiochus Epiphanes, about 170 B. C., and again by Antiochus Sidetes. In 63 B. C. it was captured by Pompey, and partly burned. It was restored by Herod. Judea having revolted against the Romans, Jerusalem was captured by Titus, A. D. 70, after a siege of five months. Irritated by its stubborn resistance, the Romans undertook its total destruction, fire being brought largely into play. The city was totally demolished, with the exception of three towers and a portion of the wall, which were left standing to shelter the legion who were

left as a garrison.—Carthage, the ancient rival of Rome, was several times burned; first in 146 B. C., after the close of the third Punic war, when by order of the Roman senate it was totally destroyed; everything that could be burned was given to the flames, the site of the city was ploughed over, and the furrows were sown with salt. In course of centuries a new town sprang up near the site of the former one, which grew to be a place of great importance, hardly inferior to Rome itself. In 439 it was taken almost by surprise by Genseric, partially burned, and made the capital of the Vandal kingdom in Africa. It was retaken by Belisarius in 533, and in 698 taken and utterly destroyed by Hassan, the Saracenic governor of Egypt. So thorough was the destruction, mainly by conflagration, that hardly a vestige remains to mark the site of either the Phœnician or the Roman Carthage.—Athens was taken by Xerxes in 480 B. C., and the next year was totally burned by the Persians under Mardonius. It was soon rebuilt, and though several times afterward captured and dismantled, it appears never to have been again destroyed by fire. Corinth, having joined the Achæan league, was devoted to destruction by the Roman senate, and was burned to the ground by Mummius in 146 B. C., the same year in which Carthage was destroyed.—The first general conflagration of Rome was about 390 B. C., when it was burned by the Gauls. An extensive fire is noted as having occurred during the reign of Tiberius, near the beginning of our era, in which nearly all the buildings on the Cælian hill were destroyed. But the great conflagration took place in A. D. 64, in the reign of Nero. It began at the lower part of the circus maximus, in some shops where combustible materials were stored up, spread northward over the whole Palatine hill, and was finally arrested at the foot of the Esquiline. The conflagration raged for six days and seven nights. Out of the fourteen regions or districts into which the city was divided, three were completely destroyed, and seven very nearly so. Dion Cassius and Suetonius affirm that the fire was the immediate work of Nero, who was disgusted with the narrow winding streets of the city; and the more judicious Tacitus rather favors the imputation. But the probability is that this is unfounded. Nero was at Antium when the fire broke out, and did not return to Rome until his own palace was threatened, which he was unable to save. It is also affirmed by Tacitus, but upon grounds hardly historical, that in order to avert from himself the suspicions which attached to him, he charged the crime upon the Christians, against whom about this time a severe persecution was instituted. Notwithstanding the great loss occasioned by this conflagration, it proved in the long run an advantage to the city; for the narrow crooked lanes were rebuilt on a regular plan, with broad streets, open places, and less lofty houses; and many excellent measures were carried into effect for guarding against conflagrations in the future. Nero himself supplied the proprietors of the burnt district with money for rebuilding, and specified a time within which the houses were to be completed; and Rome rose from her ashes far more splendid than before. In the succeeding three centuries several great fires are recorded. In 188 the capitol was destroyed by lightning; in 248 Pompey's amphitheatre was burned. Early in the 5th century Rome began to suffer from the approach of the northern barbarians, and much of it was burned by the hordes of Alaric in 410 and of Genseric in 455.—Constantinople, under its present name and its old one of Byzantium, has often been visited by conflagrations. During the crusades it suffered severely. In 1203 it was taken by the Latins; fire was set to it, and, according to Gibbon, "during eight days and nights the conflagration spread above a league in front, and from the harbor to the Propontis, over the thickest and most populous region of the city. It is not easy to count the stately churches and palaces that were reduced to a smoking ruin." When finally captured by the Turks in 1453, it was not burned. Indeed, the general practice of the Turks, unlike that of most conquering hordes, has not been to destroy the towns which they captured. Under Turkish rule it has been frequently the scene of great accidental conflagrations. The most noted of these in recent times are those of 1852, when 3,500 houses were destroyed; of 1865, in which 8,000 houses and numerous public buildings were burned; and of 1870, when 3,000 houses were burned in the suburb of Pera, and as is estimated from 500 to 1,000 persons lost their lives.—Few cities of either ancient or modern times have escaped notable conflagrations. Most of these are noticed under their respective names. Of those in London many have become historical. In 962, and again in 1087, a great part of the city was destroyed by fire. In 1212 a fire broke out on the Southwark side of London bridge, and crossed to the opposite side of the river, hemming in a numerous crowd, who flung themselves into boats and barges; 3,000 persons are said to have been drowned, and a great part of the city as it then existed was burned. The "great fire" in London took place Sept. 2–6, 1666. It began in a baker's house in Pudding lane, behind the Monument yard, and extended from the tower to the Temple church, and from the northeast gate to Holborn bridge, covering a space of 436 acres of the most densely peopled part of the city. During four days 89 churches, including St. Paul's, the city gates, the royal exchange, the custom house, Guildhall, Sion college, and many other public buildings were burned. This great fire destroyed 13,200 houses, and laid waste 400 streets; it is said that 200,000 persons whose homes had been destroyed encamped in Islington and Highgate fields. The London monument, erected in

1671–'7, from designs by Sir Christopher Wren, stands near the spot where the conflagration originated. It is a column 202 ft. high, including the base. It bore originally four inscriptions, of which three were in Latin. The English inscription, as cut in 1681, ran thus: "This pillar was set vp in perpetval remembrance of that most dreadful burning of this Protestant city, begun and carryed on by y^e^ treachery and malice of y^e^ popish faction, in y^e^ beginning of Septem. in y^e^ year of our Lord 1666, in order to y^e^ carrying on their horrid plot for extirpating y^e^ Protestant religion and old English liberty, and y^e^ introducing popery and slavery." This inscription, falsely attributing the fire to a deliberate plot of the Catholics, gave rise to the indignant couplet of Pope:

> "Where London's column, pointing at the skies,
> Like a tall bully, lifts its head and lies."

This inscription was obliterated under James II., recut under William III., and finally erased in 1831, by order of the common council of London. Many great fires, which may be properly called conflagrations, have since occurred in London. Among these are: the fire at Wapping in 1715, when 150 houses were burned and 50 lives lost; in Cornhill yard in 1748, long styled the second great London fire, when 200 houses were burned; in 1780, by the Gordon mobs, in which the destruction was great; in 1794, at Wapping, in which 630 houses were burned, including an East India warehouse, containing 35,000 bags of saltpetre, the total loss being estimated at £1,000,000; in 1803, when the great tower over the choir of Westminster abbey was burned; in 1805, 1808, and 1809, when the Surrey, Covent Garden, and Drury Lane theatres were burned; in 1814, when the custom house, warehouses, and public records were destroyed; in 1834, when the houses of parliament were consumed; in 1856, when the works of Scott Russell and co. were for the third time burned; in 1859, at London docks, where a great explosion took place; in 1861, at Cotton's wharf and other wharves near Tooley street, where were stored oil and other combustible substances. This fire lasted nearly a month, involving several lives, and a loss of property estimated at £2,000,000. For the last 40 years the fires in London, great and small, have averaged about 1,200 a year. In 1854 there were 953; in 1857, 1,113; in 1861, 1,183; in 1864, 1,715; in 1867, 1,397; in 1869, 1,572.—Copenhagen suffered from great conflagrations in 1728, when 1,640 houses were burned; in 1795, when the number was 950; and most severely in 1807, when without any declaration of hostilities the city was bombarded by the English, because the king refused to surrender to them his fleet. By this bombardment and the consequent conflagration 350 buildings were totally destroyed, 2,000 more rendered uninhabitable, and 2,000 citizens were killed.—Moscow has several times suffered severely from fire. In 1536 there was an accidental fire by which the city was nearly destroyed, and 2,000 persons perished. In 1571 the Tartars set fire to the suburbs, and a furious wind driving the flames into the city, a considerable part was reduced to ashes. It is said that 100,000 persons perished in the flames or by the sword, but this is hardly credible. In 1611 it was again burned by the Poles. But the great conflagration of 1812 is one of the most noted on record, not only on account of its magnitude, but for its historical importance. The French entered the city Sept. 14, Napoleon proposing to make it his winter quarters. On that very day several fires broke out, but little attention was paid to them by the invading army until the next two days, when they had acquired great headway. On the 17th a high wind arose, and the flames spread rapidly in every direction; by the 18th the whole city appeared a sea of flame, and by the evening of the 20th nine tenths of it was reduced to ashes. The total number of buildings destroyed is stated at between 13,000 and 15,000. The Russians at the time, in order to cast odium upon the French, attributed this conflagration to the orders of Napoleon. It is now, however, generally acknowledged that the fires were the work of the Russians themselves, and that they were kindled by the orders of the governor, Rostoptchin, acting beyond all doubt under the sanction of the emperor Alexander, without which it is hardly conceivable that the governor would have ventured such a step. The object was to deprive the French army of shelter from the winter. Ample precautions had been taken to insure the entire destruction of the city. Inflammable materials were placed in deserted mansions in every quarter, and the torch was applied simultaneously all over the city. In burning the French out of their proposed winter quarters no provision had been made for the safety of the inhabitants, who were driven to seek shelter in the surrounding woods; and it is affirmed that more than 20,000 sick and wounded perished in the flames. The direct loss to the French is put down at 40,000; and beyond this it in the end involved the retreat in the dead of winter and the almost complete annihilation of the great French army. This act, which the Russians at the time repudiated, is now considered by them as their highest glory, the greatest example in history of national self-sacrifice for the destruction of an invader.—Hamburg was the scene of a great conflagration in 1842. The fire broke out May 5, and raged till the 8th, widening its sweep as it advanced, crossing streets and leaping over broad canals, and destroying fully one third of the city. It overran 61 streets, besides numerous courts and alleys, burning 1,749 buildings, among which were the finest churches and public edifices. Large contributions for the relief of the sufferers were made all over Europe, amounting in all to not less than $2,000,000. The authorities took advantage of this conflagration to introduce an extensive system

of improvements, by laying out new and broader streets, establishing water works, and constructing sewers. For these improvements a loan of about $20,000,000 was effected, which now constitutes a considerable part of the debt of the city.—Paris has been singularly exempt from conflagrations, no great fire having occurred until those of May, 1871, caused by the communists; and these are remarkable rather for the pecuniary and historical value of the objects destroyed than for the absolute extent of the conflagration, the incendiaries not having been able to carry out their design of burning the whole city. The palace of the Tuileries was burned down, and the magnificent library of the Louvre destroyed; the Palais Royal was much injured; and of the hôtel de ville, containing works of art of priceless value which can never be replaced, only the bare skeleton of the walls remained. Various other notable palaces and public buildings were laid in ashes.—Of the great conflagrations which are known to have occurred in the cities of China we have only scanty accounts. In 1822 a fire in Canton destroyed 15,000 houses. Yedo, in Japan, seems to rival Constantinople in the frequency and extent of its conflagrations. In 1806 a fire destroyed the palaces of 37 princes, each almost a town in itself, and 1,200 lives. In 1854 an earthquake laid a great part of the city in ruins, and occasioned an extensive conflagration. The loss of life from the falling buildings and fire is stated at 200,000; but this may be presumed to be an exaggeration.—In New York considerable fires took place in 1741, which were attributed to incendiaries, and seven persons were hanged. In 1776 a fire destroyed 493 houses in Broadway, laying an eighth of the city in ashes. In 1778 another broke out on a wharf on the East river, destroying 300 buildings. In December, 1804, 40 warehouses in Wall and Front streets were burned. The first great conflagration took place Dec. 16, 1835, in what was then the main business portion of the city, the district lying east of Broadway and north of Wall street. There were burned the merchants' exchange, several banks, and 648 large warehouses, all filled with valuable merchandise; the entire loss was not less than $18,000,000. In July, 1845, another great fire took place partly on the same ground, but extending further to the south and west, the loss amounting to about $5,000,000. On Sept. 9, 1848, a destructive conflagration took place in Brooklyn, which spread over seven of the principal business blocks of the city in and near Fulton street, destroying about 500 houses.—San Francisco within the first two years of its existence had five great fires. In a year after the first discovery of gold the place had grown from a small village to a city of 30,000 inhabitants. The houses were closely crowded together, and built of the most combustible materials, while there were hardly any appliances for extinguishing fires. The first conflagration was on Dec. 4, 1849, the loss being about $1,000,000; the second, May 4, 1850, loss $3,000,000; the third, June 14, 1850, loss $3,000,000; the fourth and greatest, May 2, 1851, loss $7,000,000; the fifth, June 22, 1851, loss $2,000,000. In this series of conflagrations, following closely upon each other, the total loss was $18,000,000, an amount in proportion to the number of inhabitants fully equal to that of the great fire in Chicago.—Columbia, the capital of South Carolina, was almost totally destroyed by fire on the 17th and 18th of February, 1865. The Union army, under Sherman, had just entered the city, which had been evacuated by the confederate forces, under the immediate command of Wade Hampton. A large quantity of cotton lay piled in the streets, bales of which were cut open and set on fire. A strong wind took up the burning cotton, starting fires in many parts of the city at once, and it was only through the exertions of the Union troops that any portion of it was saved. When the confederate army evacuated Richmond, in April, 1865, Ewell, who commanded the rear guard, gave orders for the firing of the warehouses situated in the heart of the city; and when the Union advance guard entered they found a great conflagration raging, and before it could be extinguished a third of the city, embracing the entire business portion, was consumed. A very great fire, accidentally kindled in a sash factory, devastated Charleston on the night of Dec. 11, 1861. Several churches, and nearly all the public buildings, banks, and insurance offices, were burned. The value destroyed was estimated at $10,000,000. In February, 1865, when the city was evacuated by the confederate forces, fire was set by order of Gen. Hardee to all the warehouses containing cotton; a serious conflagration ensued, and about 200 persons were killed by an explosion of gunpowder.—On July 4, 1866, a destructive conflagration began in Portland, Me., occasioned by a fire cracker. Aided by a strong southerly gale, it swept due north, destroying everything in its way for a space a mile and a half long by half a mile wide. More than 50 buildings were blown up in the vain hope to check the march of the flames. It was finally extinguished on the afternoon of the 5th, after nearly one half of the finest part of the city had been destroyed. The entire loss was not less than $10,000,000.—The most destructive conflagration which ever occurred in the United States, and one of the most destructive on record, was that of Chicago, Oct. 8–10, 1871. In the region where the fire broke out were many small wooden buildings and several lumber yards. From these the fire swept westward into the part of the city which contained most of the warehouses and public buildings. The navigable river presented no barrier to the spread of the conflagration. Buildings supposed to be fire-proof burned like tinder, and the fire died out after three days, almost entirely from lack of fuel. The conflagration swept over 2,100 acres, and destroyed

17,450 buildings, among which were 41 churches, 32 hotels, 10 theatres, 8 public schools, 5 elevators containing 1,642,000 bushels of grain, 3 railroad depots, 9 daily newspaper offices, the court house, custom house, post office, chamber of commerce, and gas works. It is estimated that 98,500 persons were rendered homeless, and 200 lost their lives. The total loss is put down at $198,000,000, of which $140,000,000 was in goods and merchandise, being 47 per cent. of the entire valuation of the property in the city. Contributions for the relief of the sufferers, amounting in all to not less than $7,000,000, were received from all parts of the country and from Europe. No city ever recovered so speedily from such a blow. Within a year nearly all the burnt district had been rebuilt; and within less than two years the business of the city was supposed to have become greater by a quarter than before the fire. —Boston was in November, 1872, visited by a conflagration second in extent, in the United States, only to that of Chicago. The fire was discovered early in the evening of the 9th, and spread with great rapidity; but it appeared to have been brought under control by noon of the 10th, when an explosion of gas took place, and the conflagration became more furious than before, lasting until the morning of the 11th. The space burned over was about 70 acres, only one thirtieth of that at Chicago; but this was almost entirely occupied for business and manufacturing purposes, and was the very centre of the wholesale trade in dry goods, clothing, boots and shoes, and wool. About 800 buildings were burned, many of them of granite, five or more stories high. There were few public buildings or private residences in this space, and so not many persons were rendered homeless, and not more than 15 lives were lost. The destruction of property was about $80,000,000.

CONFUCIUS, the Latinized name of the Chinese philosopher Kung-fu-tse (Reverend Master Kung), a man who stands in a relation to the civilization of China similar to that which Moses and Socrates combined hold to western civilization. He was born, according to the best Chinese authorities, June 19, 551 B. C., in the small kingdom of Loo, which now forms a portion of the province of Shantung. Having lost his father when only three years old, his education was left to his mother, who directed his studies, and seems to have cherished in him a strong sense of morality. In his 17th year he entered the public service, but quit it at the age of 24 in order to mourn the death of his mother for three years. During this time he devoted himself to a careful study of the ancient writings, the morality of which impressed him with the idea of restoring the former usages and the doctrines of the sages of old. Having prepared himself for this task, he set himself up as a teacher at the age of 30. His fame soon spread, and his scholars and admirers increased in numbers. In order to propagate his doctrines still more extensively, he visited neighboring countries, preaching and teaching wherever he went. About 506 B. C. he returned to his native country, where he was once more called into public office and attained the high position of prime minister. But he remained in it only a short time, the intrigues of a neighboring prince having succeeded in compelling him to retire into private life. Accompanied by a number of his disciples, he moved into the dominions of the prince of Wei, and devoted the rest of his life to the dissemination of his ideas. His death occurred at the age of 72, in 479 B. C., about 10 years before Socrates was born. More fortunate than he, Confucius had during his lifetime already obtained an unbounded popularity, bordering almost on worship. Posthumous honors in great variety were conferred on him. He left a single descendant, his grandson, Tse-tse, through whom the succession has been

Confucius. (From the image in the temple of Confucius at Canton.)

transmitted to the present day. In A. D. 1671 there were 11,000 males alive bearing his name, most of them of the 74th generation. These descendants of Confucius constitute a distinct class in Chinese society. The city of Kiofoo-hien, which contains his tomb, is chiefly inhabited by his descendants, four fifths of its families bearing his surname. A magnificent temple, the most superb in China, occupies the site of his residence. In it is a statue of the sage, from which it appears that he was a tall man of imposing presence, with a large head and a red face. His tomb is a huge mound overgrown with trees and shrubs.—Considering the vast number of those by whom the doctrines of Confucius have been and are implicitly taken as the highest authority, and the influence they have exerted on the entire social and political edifice of a nation comprising fully one fourth of mankind, there is no founder of any religion who can boast of success

greater than that of Confucius. He was not, however, the originator of a religious creed. While striving to introduce a ritual more minute than that of Moses, he rejected divine revelation, and erected a structure of moral philosophy founded upon the wants and tendencies of human nature. There was a time when European philosophers vied with one another in extolling the merits of Confucius as one of the sublimest teachers of truth among mankind. This was especially done by the French encyclopædist philosophers of the 18th century, who, in order to strengthen the position they had taken against divine revelation, proposed to prove by the examples of Confucius, Socrates, and others, that the holiest truths had found their best interpreters among pagan philosophers. Certain it is that the doctrines of Confucius bear a strong resemblance to those of his Greek contemporaries, not merely in their ethical tendency, but also in the abstruse metaphysical reasoning upon which they are apparently founded. The books containing them, partly written by Confucius himself, partly by his disciples (see CHINA, LANGUAGE AND LITERATURE OF), bear almost the same relation to the Chinese world as the Bible does to the Christian. The knowledge of one's self is, according to Confucius, the basis of all real advance in morals and manners. The duties man owes to society and himself are minutely defined by him; and there are many passages in his writings closely approaching the Christian standard of morality. Having been asked whether any one sentence could express the conduct most fitting for one's whole life, he replied: "Do not unto others what you would not have them do to you." "It cannot be denied," says Dr. Williams, "that among much that is commendable, there are a few exceptionable dogmas among his tenets; but compared with the precepts of Grecian and Roman sages, the general tendency of his writings is good; while in their general adaptation to the society in which he lived and their eminently practical character, they exceed those of western philosophers."

CONGAREE, a river of South Carolina, formed by the union of the Broad and Saluda at Columbia, near the centre of the state. After a course of about 50 m. it receives the Wateree, below which it is called the Santee. The river is navigable by steamboats to Columbia.

CONGESTION, strictly speaking, an accumulation of any liquid in an organ or tissue, but generally limited in medical works to an abnormal amount of blood in the vessels of a part otherwise healthy, and in most cases from an enlargement of the minute arteries and capillary blood vessels. Congestion may also be passive from obstruction to the circulation from external or constitutional causes. Congestion, called *hyperæmia* by Andral, may be entirely independent, as to its cause, of the organ or tissue in which it is seated. The highly vascular organs, and those which receive the blood most directly from the heart, as the brain, the lungs, the liver, and the spleen, are the most frequent seats of congestion, together with their capillaries. Congestion differs from inflammation, to which, however it may lead, in its anatomical characters: in the former the organization and vital characters are unaltered, and the post-mortem appearance of sanguineous accumulation may be removed by the action of water; but in the latter the redness is permanent, the consistence is changed, and various morbid products are effused; though congestion precedes inflammation, it does not necessarily proceed to it. There are certain conditions of the circulation in which congestion may be said to be normal and physiological; as, for example, in the erectile tissue of the nipple and other organs, and in the superficial coloration of the blushing cheek. Andral makes three degrees of congestion: 1, in which an increased amount of blood is sent to a part; 2, in which, in addition, the capillaries are dilated, with retardation of the circulation, a tendency to coagulation of the blood, and darker color of the tissues; this is the true type of congestion; 3, in which there is complete stagnation of the blood, with a darker coloration. As the first of these degrees is less than congestion, as ordinarily understood, so the last is more than congestion, involving a new condition of the affected parts. As congestion is a commencement of disease in many organs, the functional disturbances arising from it are various. It is not always easy to ascertain the predisposing and exciting causes of congestion, though it may be stated as a general rule, that repeated stimulation of an organ or tissue predisposes it to congestion; inflammation in a neighboring part may induce congestion, as for instance in the brain during inflammation of the air passages; an unequal distribution of blood from cold or other causes may cause pulmonary or other visceral congestions. The redness and swelling are in proportion to the accumulation of blood; the heat and pain are trifling, unless the congestion be extreme; the distention of the vessels may end in their rupture, and in circumscribed or diffused hæmorrhage, though effusion of blood may also occur from a diseased state of the fluid, as in typhus, scurvy, and the œdematous congestions of chlorosis, without rupture of the vessels. It appears from the experiments of Magendie that a diminution in the proportion of fibrine in the blood, from any cause, predisposes to congestion; Andral noticed also a diminution of this element in many cases of cerebral congestion, beginning with headache, dizziness, and bleeding at the nose, and ending often in coma and apoplexy. Congestions of the brain and spinal cord, if of long duration, or ending in hæmorrhage, are highly dangerous and frequently fatal; the spleen is sometimes congested to the point of rupture, causing death, without any premonitory symptoms. Frequent congestions of an organ bring on hypertrophy, thickening,

and a disposition to inflammation; they are generally of short duration, and vary in severity from the apoplectic congestion of the brain to the simple swelling of a hæmorrhoidal tumor; their seat is very frequently changed in many hysterical females. The liver is almost always more or less congested at the moment of death; this condition may exist in its whole substance, the lobules presenting a nearly uniform dark color throughout; or the centres alone may be thus colored, the circumference being lighter; in this, the first stage of hepatic venous congestion, in which the hepatic veins are full and the portal plexus empty, the appearance is due to the continuance of capillary action after the general circulation has ceased; in the second stage, the portal as well as the hepatic venous system is congested, and the obstructing cause may be either in the liver, in the heart, or in the general venous system; occasionally the portal system is congested, the marginal portions of the lobules being darkest colored. A common form of venous congestion depends on deficiency of tone in the veins, which prevents the normal ascent of the blood from the lower parts of the body, thereby distending the vessels and causing an accumulation of blood; in this condition the serous parts of this fluid are prone to escape, forming dropsical effusions and anasarca. This inability of the blood to ascend against gravity is found in a great variety of chronic diseases, the consequences of improper food, unhealthy habitations, or even the natural results of old age; the want of tone in the system is aggravated by ulcers, gangrene, and effusions of blood and other fluids into the cavities and tissues.

CONGLETON, a market town and borough of Cheshire, England, 22 m. S. of Manchester; pop. in 1871, 11,344. It is situated in a deep valley on the river Dane. The principal street, a mile in length, is paved and lighted with gas, and has many old houses of timber framing and plaster. There is an Episcopal church, a Catholic and several dissenting chapels, a town hall, public assembly rooms, and a number of charitable institutions. Silk manufacture is the staple industry, but there are also manufactories of cotton and leather. Near it are lime quarries worked under a cliff 1,091 ft. high.

CONGLETON, Henry Brooke Parnell, lord, a British statesman and author, born July 3, 1776, died June 8, 1842. His father was Sir John Parnell, chancellor of the Irish exchequer, who was second in descent from the poet Parnell. He entered parliament at an early age, and for nearly 35 consecutive years represented the constituencies of Queens county, Ireland, and Dundee, Scotland, in the house of commons. In 1841 he was raised to the peerage as Baron Congleton. He belonged to the most liberal section of the whig party, and was a cabinet minister under the Grey and Melbourne administrations. He was one of the first to advocate the repeal of the corn laws. He is the author of treatises on "The Principles of Currency and Exchange," "The Penal Laws against the Irish Catholics," "Paper Money, Banking, and Overtrading," "Financial Reform," &c. He suffered from alienation of mind in the latter part of his life, and died by his own hand.

CONGLOMERATE, in geology, a rock composed of rounded pebbles, such as are seen frequently forming a beach rolled by the waves. These fragments of older rocks, cemented together by a calcareous, silicious, or argillaceous paste, constitute a conglomerate, or, as it is sometimes called, a puddingstone. The pebbles may be of any size larger than sand; when composed of the latter, the rock is called a sandstone. Strata of this nature are found in all the geological formations of sedimentary origin. The most interesting example, perhaps, is the great conglomerate bed which forms the floor of the coal formation, and is composed of white quartz pebbles of all sizes, up to that of a man's head. The rock is traced beneath the coal formation of the middle states, and a similar one occupies the same relative position in England, where it is known by the name of the millstone grit.

CONGO, a country of Africa, extending from about lat. 4° 30′ to 8° 30′ S., bounded N. by the river Congo or Zaire, E. by a range of mountains parallel to the coast, S. by the river Dande, which separates it from Angola, and W. by the Atlantic ocean. Numerous rivers descend from the mountains on its frontier and flow through it to the sea. Of these, the Lilundo, Ambriz, and Onzo are the most considerable. The coast region of Congo is unhealthy because of its alluvial plains and forests, but the inland climate is comparatively salubrious. The soil produces in abundance an immense variety of tropical plants and fruits. Several species of grain unknown in Europe and America are raised on the banks of its rivers, the most valuable of which is the *luko* or *luno*, which yields a white and delicious bread. The principal products are, however, rice and maize, of which three crops are often raised annually. Of the forest trees, the most remarkable is the baobab. The oil palm is also common to this country with all the regions of western Africa. Prof. Smith, in the expedition of 1816 to Congo, brought home to Europe 620 species of plants and flowers, 250 of which are said to be altogether new. The elephant, lion, leopard, zebra, gazelle, and antelope are the principal animals. The rivers are frequented by hippopotami, turtles, and crocodiles, with excellent fish, one of which, the *sparus*, often weighs from 30 to 60 lbs., and is of very delicious flavor. No domestic animals are employed as beasts of burden or in the performance of agricultural labor. Sheep and horned cattle are scarce, but goats, hogs, and poultry are plentiful. Among the reptiles are the boa, the chameleon, and the flying lizard or palm rat, which is deified by the natives. Ostriches, peacocks, and parrots are abundant. Some of the insect

tribes are very venomous. The sting of the *banzo* is said to be mortal; the proboscis of the *insondi* penetrates the trunk of the elephant and inflicts madness and death. The imports are chiefly cloths, stuffs, carpets, and hardware and earthenware from Europe, together with fruits, grain, and various other kinds of American produce from Brazil. The exports consist principally of ivory, furs, and slaves, who were formerly shipped annually in large numbers to the western world. Congo was once exceedingly populous, but the ravages of the slave trade for three centuries have so wasted and diminished the people that the statements of the early Portuguese missionaries relative to its ancient populousness are now often discredited. One of these relates that a king of Congo marched against the Portuguese at the head of 900,000 men; but Tuckey found no town with more than 600 inhabitants. The

Royal Guard.

natives of Congo are of ordinary stature. Their color and features are less strongly marked than those of most other negroes, but they are both more indolent and less intelligent than the generality of their race. Polygamy is tolerated among them, but adultery is severely punished. Slavery is the penalty for all crimes save murder, the perpetrator of which is put to death. When a chief dies, they kill a certain number of slaves proportioned to his rank, that he may have attendants in the other world. The people practise fetish worship. They are unacquainted with the plough, and prepare the ground for the seed by scratching it with a hoe. The rights of property are rigidly observed among them, and its subdivision is sometimes carried to such excess that three or four persons will own a fowl or a hog between them. Society in Congo may be said to consist of the following classes: 1. The *chenoos*, or chiefs, and their families. The dignity of chenoo is hereditary in the female line; when a chief dies he is succeeded not by his son, but by a brother or maternal uncle. The chenoo is little distinguished from his subjects by his dress or dwelling. His sceptre is a small staff of black wood, inlaid with lead or copper. 2. The *mafooks*, who collect the revenue and carry on trade. 3. The *foomoos*, or farmers, who have houses and lands of their own, two or three wives, and a few slaves to work for them. 4. Fishermen and laborers, who have no property of their own. 5. Domestic slaves, who are said to be not transferable, except when guilty of some great crime. The kingdom of Congo is divided into several provinces, each of which has its *banza* or capital and chief, who owes feudal allegiance to a lord paramount at the capital, Congo-banza, or San Salvador, near the Lilundo, about 50 miles from the sea. This potentate is styled the *lindy* of Congo; but, though once very formidable, he is now unable to check the encroachments of the provincial and village chenoos, most of whom are practically independent, and frequently at war with each other and the lindy.—Congo was discovered in 1484 by the Portuguese, under the command of Diogo Cam, who soon afterward made settlements and erected forts along its coast. The language is said to resemble that of the Caffres and Bechuanas.

CONGO, or Zaire, the largest river of western Africa S. of the Niger. It has also been called the Barbela, but the native appellation is Moienzi Enzaddi, "the great river," or "the river that absorbs all other rivers." Its source is unknown, but tradition among the natives places it in a marsh situated near the equator, about lon. 18° E. It flows into the Atlantic ocean near Point Padron, near lat. 6° S., lon. 13° 30′ E., and is from 7 to 10 m. wide and more than 160 fathoms deep at its mouth, with a velocity of between 4½ and 5 knots an hour. The Congo has been ascended by Europeans to a distance of 280 m. inland. In the lower part of its course it exceeds 5 m. in width, and, with the exception of a portion called the narrows, maintains a breadth varying from 1 to 4 m. throughout its whole known extent. The narrows extend some 40 m. above a point 140 m. from the coast, where the tide is still perceptible, causing a rise and fall of from 12 to 16 inches. Here the river flows turbulently between steep banks of rock not more than 500 yards apart, and is obstructed by rapids and the so-called Yellala, or cataract, of which the fall, however, is only 30 ft. in 1,500. Geographers estimate that the Congo drains an area of 800,000 sq. m. Regarding the depth of the river as 60 ft. and its breadth as 9,000 ft., which are believed to be fair approximations, the outflow of water is 1,800,000 cubic feet per second. This is greater than that of the Mississippi.

Between the cataract and the sea not a single tributary falls into the river on either side. Near the coast the stream is studded with islands, and the adjacent country is low, level, and swampy, abounding in mangrove growths. Further inland hills rise parallel to the banks, and not far from them, to a height of 2,000 ft. The vegetation of the valley is for the most part exceedingly luxuriant. The river forms the N. boundary of the kingdom of Congo, which it separates from Loango. It was once thought to be the outlet of the Niger. The German geographer Petermann regards it as identical with the great river Lualaba recently discovered by Livingstone in central Africa, and hence as connected with the vast lacustrine system of the equatorial region. Capt. J. K. Tuckey of the British navy, who explored it in 1816, then expressed the opinion that "the Zaire will be found to issue from some large lake or chain of lakes, considerably to the northward of the line." Further explorations of the Congo by scientific expeditions from Europe are now (1873) in progress.

CONGO SNAKE (*amphiuma means*, Linn.), one of the batrachian family of the *amphiumidæ*, destitute of gills except at the earliest periods of life, breathing by exposed spiracles or branchial openings on the sides of the neck, and undergoing, according to Holbrook, no metamorphosis. Its general aspect is snake-like; the head large, lips thick and extensile, snout depressed and rounded, neck contracted with a transverse fold at the throat; numerous small teeth on the maxillary and palate bones; a single spiracle on each side of the neck; limbs four, the anterior very small, with two fingers, and the posterior still smaller, with two toes. It is found in the southern and southwestern United States, attaining a length of 28 inches, of which the head is 2 and the tail 6 inches; deep bluish black above, tinged with violet, lips and throat lighter, and under surface dark purple. These animals live in muddy waters, or in the mud, burrowing in the ditches of the rice fields, and feeding on small fish, mollusks, and insects; they are sometimes found on land, apparently seeking a favorable locality. They are considered by the southern negroes as highly venomous, but are really entirely harmless. —In the *A. tridactylum* (Cuv.), the anterior fingers are three and the posterior also; the different number of fingers is the principal distinction between this and the other species.

Amphiuma means.

CONGREGATIONALISM, a form of church polity, or a system of ecclesiastical organization, management, and control. Its correlatives are Presbyterianism, Episcopacy, Papacy. Its essential peculiarity is that it maintains the independence of each particular congregation of Christians, and their sufficiency to perfect and preserve their own organization, to elect and inaugurate their own officers, and, with and through those officers, to perform all needful ecclesiastical acts. Like every other system of church order, it may be connected with any form of doctrine, and with any particular mode of worship. This polity in its general principle is adopted not only by those known as Congregationalists, but also by the Baptist denomination, and in this country by Unitarians and Universalists, and by some who hold the theological opinions of the Methodists. In the common, though more limited and strictly denominational sense in which it will be used in this article, the word Congregational designates a class of churches which hold in general that system of theology which was maintained by Augustine and Calvin, and which has been explained, advocated, and amended by the theologians of New England in their successive generations.—Congregationalists define a church to be an organization of professed believers, statedly meeting in one place, and united together by covenant for mutual watchfulness and edification, for the maintenance of divine worship and the observance of Christian ordinances. There is no "Congregational church of the United States," but a collection of Congregational churches. Hence their efforts are not directed so much to "church extension" as to the multiplication and strengthening of churches. The definition given implies an organization, and not a mere accidental assembly, composed of believers in Christ, who profess to be converts, and who give credible evidence of piety by lives of holiness; they become members by election and by mutual covenant, for the sake primarily of the objects stated. Church members, in their individual capacity, are reasonably looked to as leaders in every good work; they are expected, as opportunity offers and conscience dictates, to coöperate in missionary, educational, and reformatory enterprises. In fact, these enterprises owe their chief strength and efficiency to the enlightened and conscientious support of Christians; yet a church in its organic constitution does not exist specifically for any such enterprise, and is seldom called upon as an organization to endorse or espouse specific measures of social, political, or moral reform extraneous to its own body. There is some difference of opinion concerning the relation of the baptized children of Christian parents to the church; but the universal usage is to admit them to full communion only upon satisfactory evidence of their conversion and piety. A church thus defined is to be distinguished from the congregation, which includes all who meet in the same place, non-communicants as well as the church members;

from the society, which is a legal term, denoting those especially incorporated for holding real estate and providing for the expenses of the church; and from the parish, a term nearly synonymous with the two preceding words, but sometimes also used to mark territorial limits. Hence also are derived such terms as church members, pew-owners, and parishioners. It is of course an object with every church to gather around it a congregation from which it may receive accessions to its ranks; but the society or parish organization is an unessential thing, and simply a matter of convenience. Congregationalists insist on the competence of each church to elect its own officers, to regulate its own concerns, to receive or reject candidates for membership, and to pronounce censure upon any one of the brotherhood who walks disorderly; and on its independence, in these matters, of all dictation from other churches, its allegiance being due to Christ alone. Moreover, it is a principle of Congregationalism that in the administration of church affairs the brethren of the church have equal rights. Each male member of full age is entitled to vote on all matters affecting its interests.—The internal structure of a Congregational church is very simple. Its officers are a pastor or pastors and deacons, the latter elected from and by the church, and the former usually called from the same office in some other church, or selected from candidates for the ministry who have a general recommendation from those already in the pastoral office, and who have made trial of their gifts in the pulpit to the satisfaction of the congregation. In the election of a pastor, it is usual for the church to nominate to the society, and upon their concurrence an invitation is given to the candidate. Provision is made for his support, a revenue for this purpose being secured by subscription or by a tax, or by the rent of seats in the house of worship. Upon his acceptance he is inducted into office by a council, being ordained if he has never been set apart for the work of the ministry, but otherwise only installed. It is usual also for churches to appoint a clerk to keep their records, and a committee of the brethren, who, in connection with the pastors and deacons, examine candidates for admission, inquire concerning cases of scandal, if any arise, and have a general oversight of the interests of the church. The pastor is the moderator of the church, the spiritual counsellor of its members, and its authorized teacher, who has entire control of the pulpit, administers the ordinances of baptism and the Lord's supper, and performs the marriage ceremony. The deacons are officially the almoners of the church charities, being specially charged with responsibility for the sick and needy, while, in consequence of their position and experience, they are naturally looked upon as the counsellors of the minister. Congregationalists hold to but one order or rank in the ministry, the deacons being only laymen. Licentiates are not ministers, but simply candidates for that work. Evangelists are ministers who preach and administer the ordinances, but who have no permanent place of labor. Missionaries are ministers who have been sent to destitute places, or to foreign lands, after ordination. Ministers who are employed to preach to churches year by year, without the formalities of an installation, are sometimes called stated supplies. The use of the terms bishop and overseer, as designations of church officers, is not common in Congregational churches; but when they are employed, they denote simply the pastor of a church. The Baptists frequently designate their ministers as elders. In early times the New England churches made a distinction between the work of a pastor, a teacher, and a ruling elder, and these three officers formed a presbytery in every church, whose concurrence with the brotherhood was necessary for the consummation of every church act; but for a long time the pastor has been the sole representative of this presbytery, and the distinction is known only as a matter of history. The Congregational "ruling elder" is not to be confounded with the ruling elder of the Presbyterian church. The former was an ordained and ordaining minister, though he was not a professional preacher, and did not administer baptism and the Lord's supper. Congregationalists advocate and practise church discipline by means of admonition and rebuke, and an entire withdrawal of fellowship. This is done by the votes of the brethren, after patient waiting and a full hearing of facts. Its design, so far as the offender is concerned, is to bear testimony against his fault, and to express to him the conviction of the church of his danger if he fails to acknowledge and forsake his sin. So far as the church is concerned, an act of excommunication frees its members from responsibility for him whom they disown. Excommunication is attended with no civil disabilities, and one who has been cut off may be restored to fellowship upon confession and repentance.—The liturgy of Congregational churches is as simple as their organization. The ordinary public service of the Sabbath provides for extemporaneous prayers, the singing of psalms and hymns, the reading of Scripture, and delivery of a sermon, written or unwritten. The order is modified when desirable, and the exercises close with the benediction. No audible responses are made as prayer is offered, but in theory it is accepted as the devout desire of each worshipper, while in song all may pour forth their hearts before God in vocal utterance. The custom in respect to posture during prayer and singing varies in different congregations. The most usual is to sit during prayer and stand during singing. A form is used in the reception of members, in which usually their assent is asked to the covenant of the church and to the confession of faith adopted as the common expression of their views of Christian doctrine. Some Congrega-

tional churches have adopted a form of prayer for their own use in public worship, and congregational singing is now generally practised in churches of this order.—For the office of the ministry in the Congregational churches several things are requisite. A personal and experimental knowledge of divine truth is indispensable. To this must be added usually a liberal education and a familiarity with theological science. One having these qualifications, and desirous of becoming a preacher, may, upon examination by an association, be recommended to the churches as a candidate. If any church then elects him as pastor, and he accepts the invitation, a council is called to examine and ordain him. The services at ordination are performed by the ministers invited to the council, and include not only devotional exercises, but a special sermon; the ordaining prayer, in which the candidate is solemnly set apart for his office with the laying on of the hands of other ministers; the charge, in which he is reminded of the duties of his office; and the right hand of fellowship, which is given him in the name of the ministers and churches, with their Christian salutations.—Without admitting any right of churches to exercise authority and control over each other, Congregationalists seek to strengthen bonds of love and fellowship between all the churches of Christ, and especially between those of the same faith and order. Neighboring churches may be regarded as so many Christian families, having common sympathies and aims, desirous of promoting each other's welfare, ready to assist and advise as occasion may require, at liberty to suspend intercourse as a last resort, but not authorized to dictate measures or prescribe laws for each other. This mutual fellowship finds expression in various ways. The pastors of neighboring churches frequently exchange pulpits for a Sabbath; membership in one church is recognized as a ground of invitation to communion with others; church members changing their residence are dismissed and commended by letter to other churches which they desire to join, and thus their connection is transferred from one organization to another. The censures pronounced by a church are also respected by those in fellowship with it. Any church may call a council by letters addressed to neighboring churches, to give advice. This step is customary at the settlement and dismissal of pastors, and at the organization of a church; and a council thus convened, consisting of a pastor and a delegate from each church invited, is regarded as a representative of all the churches. A member thinking himself aggrieved by church action has a right to demand a council, and to designate half the churches to be invited; if his request is refused, he may call an *ex parte* council. Such councils dissolve when their business is ended. Occasionally, councils are more permanent bodies, and are called consociations, and sometimes conventions. Such bodies, however, should not be confounded with presbyteries, from which they differ both in their structure and in their powers. A presbytery is composed of representatives from church sessions; a consociation, of delegates from the churches directly. A church may at any time withdraw from a consociation without impairing its standing. The powers of a consociation are delegated and defined by the churches, and may at any time be curtailed or withdrawn, or the body itself may be dissolved without affecting the existence of the churches connected with it. In the Congregational system the particular church is the source of all ecclesiastical power and privilege. Sometimes neighboring churches unite in conferences for religious services and for reports of benevolent operations. Associations are in general composed of ministers, who meet for personal improvement and intercourse, and also to examine the credentials and attainments of candidates for the ministry, and recommend them to the churches. Sometimes associations include also a delegation from the churches, but without having authority in ecclesiastical matters. The general associations are organizations, made up of representatives from the local associations, meeting annually, but not infringing upon the independence of the churches. They may recommend, but cannot speak authoritatively. Occasionally larger synods or conventions have been held, though purely for deliberative and declaratory purposes; as at Cambridge, Mass., in 1648; Saybrook, Conn., 1708; Albany, 1852; and Boston, 1865. The last included over 500 delegates from more than 24 states, and made important declarations of faith and polity. In 1871, at Oberlin, Ohio, a national council of 290 delegates, from 25 states, organized a permanent body, to meet triennially, under the name of "The National Council of the Congregational Churches of the United States." Thus Congregationalism insists on the fellowship of the several churches no less than on the independence of each church. The churches are independent as respects authority, not as respects communion. "Those devout and studious men in England, who reduced to practice the conclusion that churches in modern times, like those in the apostolic age, should be quite independent of lords or commons, or of king or Cæsar, and equally independent of a supposed national church unknown in the New Testament and to the early ages of ecclesiastical history, were at first called Independents; and in England the pædobaptist churches, independent of the state, and independent of any existing or imaginary church of England, have always been distinguished by that name." In America different circumstances have led to the general use of the term Congregationalists.—The doctrines taught in the Congregational churches profess to be in accordance with the Scriptures, and correspond in general with those taught in the articles of the Church of England, and

with the confession and catechisms compiled by the assembly at Westminster in 1643. It is customary for each church to have a summary of tenets in which its members are agreed, and to which the assent of candidates for membership is expected. These summaries differ in minuteness and in phraseology, and from time to time may be modified to meet prevalent forms of error, and bear testimony to the truth. Inasmuch as the inspired word of God is received as the only perfect standard of belief and rule of duty, church creeds have not usually been employed to exclude from communion the real subjects of experimental religion. They are intended to express, "not denominationalism, but catholicity." Many of the churches of New England were constituted without particular creeds, and candidates for admission added to the relation of their religious experience either a confession of faith of their own composing, or an intimation of some received confession to which they adhered. Congregational churches are pædobaptist, recognizing the right of Christian parents to present their children for baptism, which is regarded as the counterpart of circumcision and the seal of God's covenant with Abraham. While the principles of Congregationalists allow them to recognize other local churches not conforming exactly to their faith and order, they do not hesitate to appeal to Scripture in support of their own customs. There they claim to find evidences of a popular church government, analogous to that in the Jewish synagogues; distinct local churches, instead of one national or provincial church, *e. g.*, the seven churches of Asia Minor; the right exercised in those churches of electing officers and teachers, as an apostle, Acts i.; deacons, Acts vi., 2 Cor. viii. 19; elders, Acts xiv. 23; also the right of administering ecclesiastical discipline, Matt. xviii. 15–18, 1 Cor. v. 3–5, 2 Cor. ii. 6–11, &c.; and an identity of bishops with presbyters, Acts xx. 17, 28. They find confirmation of their views, not only in the history of the apostolic churches, but in the course of events in the next century, according to the concessions of ecclesiastical historians of other denominations, such as Waddington, Mosheim, Neander, and Gieseler. —The influence of Congregationalism has entered most fully into the development of our national history, especially in New England and the northwest. The Congregationalists, while claiming Scriptural warrant for their polity, do not feel themselves troubled in making the admission that the discovery and practical use of their principles is of recent date. Relying on present evidences of life and truth in churches, they do not feel themselves bound to trace the visible links by which the ordinances have been transmitted to them since the apostolic days. In their view each local church exists really and rightfully, not because it existed in a previous generation, but because it holds to the head, which is Christ, and is composed of men renewed and sanctified. He who would trace their history should go back 300 years, and examine the state of things in the established church of England when Queen Elizabeth's accession to the throne made her the supreme head of the church. The Puritan party in that church grew up out of an unwillingness to conform to usages which they esteemed idolatrous, such as the wearing of the surplice, the use of the sign of the cross, and kneeling at the communion. Persecution followed. Some of the Puritans disowned the church entirely, and became separatists; others adhered to it, protesting against its errors, and were simply nonconformists. Of the former class was Robert Brown, who in 1586 propounded a theory of church government, more radical and exclusive than that which was afterward advocated by John Robinson, who is generally esteemed the father of modern Congregationalism. Before the close of the century the Brownists were numbered by thousands. In 1602 "several religious people" in the north of England, driven by their troubles "to see further into these things by the light of the word of God," determined to "shake off this yoke of anti-Christian bondage, and, as the Lord's free people, join themselves by covenant into a church state, to walk in all his ways, made known or to be made known to them, according to their best endeavors, whatever it cost them;" and, added Gov. Bradford nearly 30 years after, with touching simplicity, "that it cost them something, this ensuing history will declare." Over a portion of this church, which had been divided for the convenience of its scattered membership, Robinson was pastor, and in 1608 he went with it to Holland. There they remained several years, until it became evident that a return to England was hopeless, and that Holland was not the place for their permanent home; and having great hope of advancing the kingdom of Christ by coming to this western world, they prepared for another removal. The church was again divided; the pastor remained temporarily with the majority in Leyden, and the colony took with them their elder, William Brewster, it being agreed that those who went first should be an absolute church of themselves as well as those who stayed. This young church, receiving Robinson's benediction at Delft Haven in 1620, was transported in the Mayflower to Plymouth, where the colonists, having first organized themselves as a civil body politic, landed, Dec. 21, literally "a church without a bishop, and a state without a king." Robinson died in 1625, before he could join them in America. This was the first church in New England. The first church formed in New England was that gathered at Salem, Aug. 6, 1629. The first settlers of Massachusetts Bay had apparently no intention at the outset of separating from the church of England, and their ministers were persons who had been episcopally

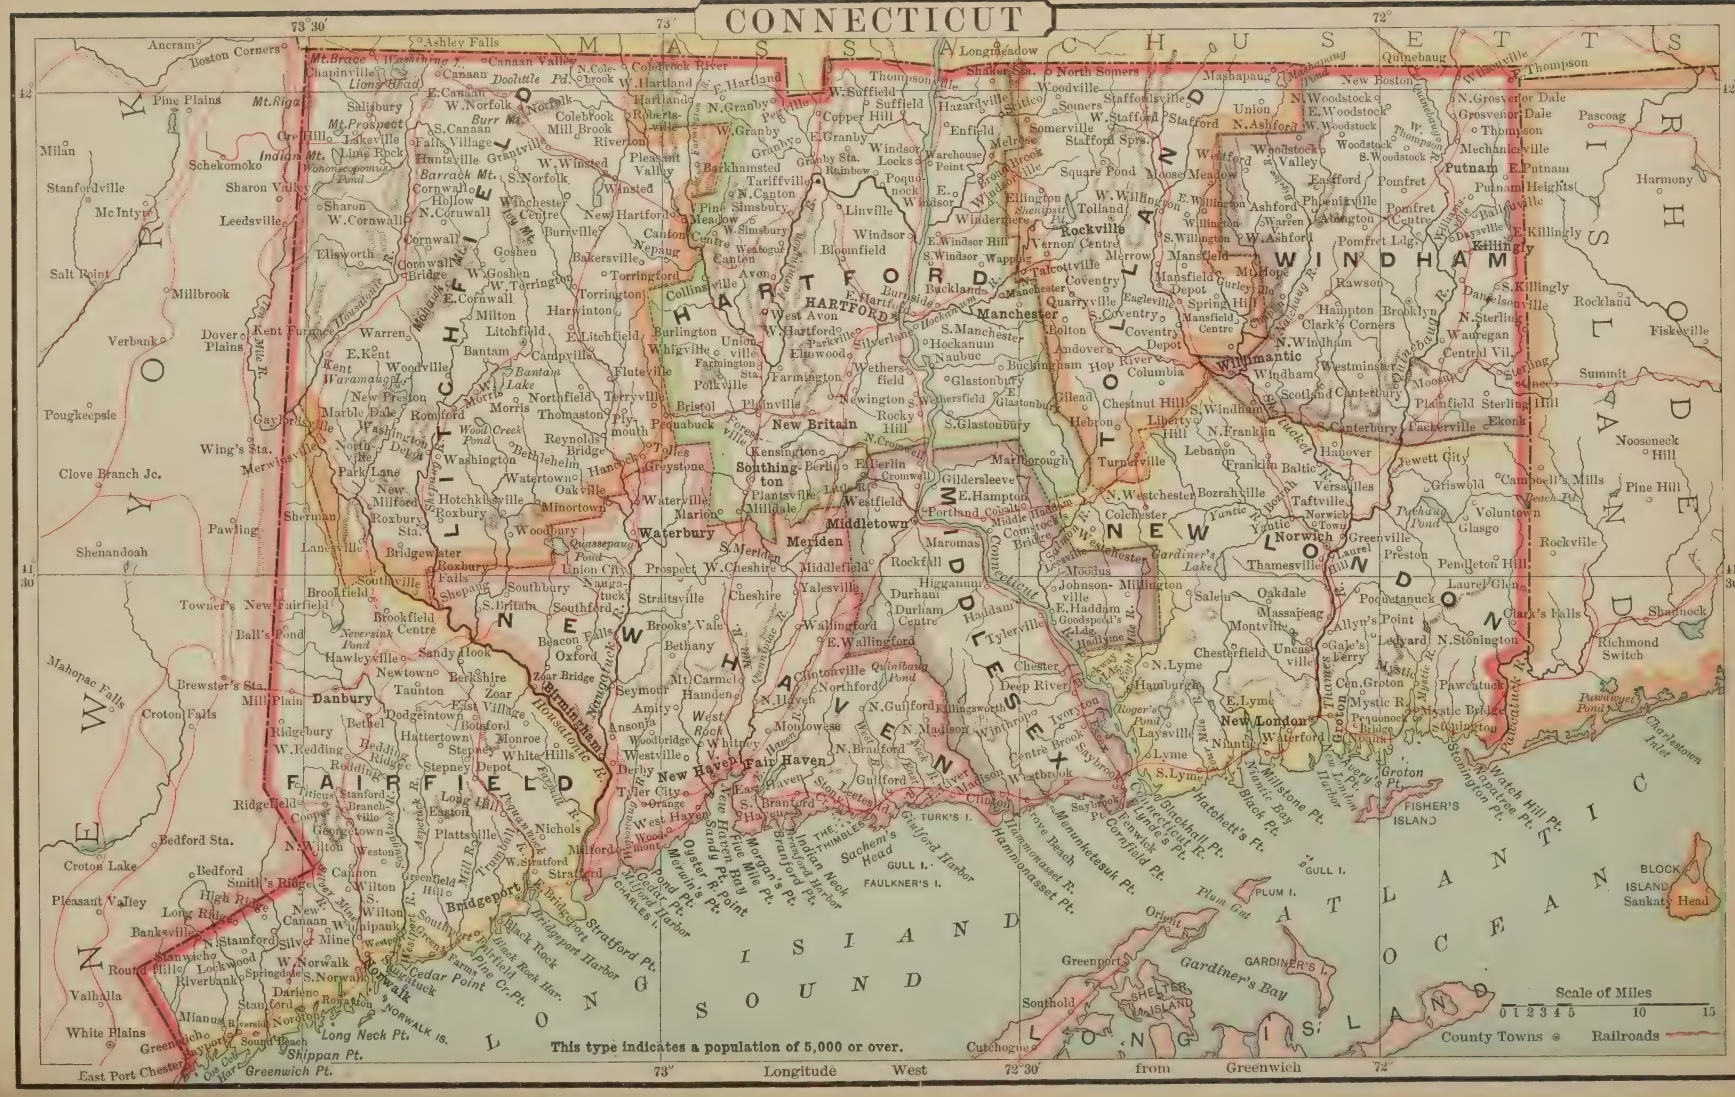
ordained; but once in America, there was, as Robinson had predicted, but slight difference between the nonconformists and the Plymouth pilgrims. The same thing is true of the settlers of the Connecticut and New Haven colonies, who sought to be free, not from the Anglican church, but from its errors and corruptions. Notwithstanding the hardships involved in the planting and training of Christian churches in this new land, the Congregationalists who remained in England were even less favorably situated for extending their views of church polity. The civil commotions in the middle of the 17th century, and the persecutions and ridicule it encountered in the reign of Charles II., checked the growth of the system in its youth, while the distinctions of society and the disabilities resting on dissenters from the established religion have been a perpetual incubus upon it.—The Congregational ministry has been filled by well educated men. The earliest of them were graduates of the English universities. Some of them were men of rare attainments and scholarship. Harvard college was established at an early day, with special reference to the wants of the churches. Before 1640, 77 clergymen had left the pastoral office in England for the work of the ministry in New England, and 14 more, pursuing a course of theological study, had come here to complete it, and to enter the ministry. In 1665 the commissioners of Charles II. reported of the people of Connecticut, "that they had a scholar to their minister in every town or village." The Congregational churches of Connecticut down to the year 1832 had had 947 ministers, of whom all but 33 were regular graduates of some college. Among eminent men of this denomination it is sufficient to mention the names of John Milton, John Owen, Howe, Watts, Doddridge, J. Pye Smith, Harris, and Wardlaw; and in this country, the Mathers, the Edwardses, Shepard, Bellamy, Hopkins, Emmons, Dwight, Stuart, and Taylor.—The Congregationalists generally have carried their liberality so far as to neglect in great measure the extension of their polity in its pure form. Multitudes of them have gone into other ecclesiastical connections, by an easy transfer, in changing their residence, and particularly in emigrating westward. The Presbyterian family of churches has been greatly indebted to this largeness of spirit and lack of denominational zeal. The present century has been distinguished for large and efficient plans of benevolent action. In many of these the Congregationalists have taken the lead, furnishing men and means without grudging.—The "Congregational Year Book," published by the Congregational union of England and Wales, contains lists of churches connected with county associations, and an alphabetical list of Independent ministers in Great Britain and the colonies. In the summary reported for 1872, it is stated that the number of county associations and unions throughout the British empire, and in the foreign missions conducted by British missionaries in Madagascar, was 75 (40 in England, 16 in Wales, 8 in Scotland, 1 in Ireland, 9 in colonies, 1 in Madagascar); of pastors, 2,716; of ministers without pastoral charges, 603; of churches, 3,609. There were 29 colleges and institutes, with 567 students. The number of periodicals conducted by Congregationalists in the British empire was 4 annual, 2 quarterly, 21 monthly, and 3 weekly, in the English language, and 10 periodicals in Welsh. The British Congregationalists, like other evangelical dissenters in England, do much for the support of the London missionary society, which in the year 1871–'2 disbursed £113,213, of the British and foreign Bible society, of the religious tract society, and of other similar institutions. The most important among the strictly Congregational societies are the home missionary society, established in 1819, the receipts of which in 1871–'2 were £6,591; the Irish evangelical society and Congregational home mission, established in 1814 (income, £2,902); and the Colonial missionary society, established in 1836 (income, £2,900). In France there is a "Union of Evangelical Churches," which embraces Congregational as well as Presbyterian societies (numbering 45 in 1872), but the former are in a large majority. There were also 9 Independent churches unconnected with the union, and 19 churches supplied by the evangelical society of France. In Switzerland there are evangelical free churches of the same order in the cantons of Geneva, Bern, Vaud, and Neufchâtel; and in Belgium there are 15 churches of this class. According to the "Congregational Quarterly" for January, 1873, there were in 1872 in the United States 2,487 Congregational churches, 318,916 church members, and 371,110 pupils in Sunday schools. Besides a large number of colleges in whose administration this denomination takes an active part, it has theological seminaries at Andover, Bangor, New Haven, Hartford, Oberlin, Chicago, and Oakland, Cal. Congregationalists were formerly associated with the New School Presbyterians in the American board of commissioners for foreign missions; but the union has of late been dissolved, and the board is now under the exclusive control of the Congregational churches. Its receipts for the year ending October, 1872, were $428,693. It sustains 16 missions, with 77 stations, 445 out stations, 173 churches, and 9,019 church members. The American home missionary society had an income of $294,566, and the American missionary society of $330,-146. The periodicals published in the interest of Congregationalism embrace 4 quarterlies and 7 weeklies, besides several Welsh publications.—The writers and authorities upon this subject are numerous. Among more recent ones, in whose volumes will be found abundant references to the older, we mention Davidson on the "Ecclesiastical Polity of the New Testament;" Uhden on the "New England The-

ocracy" (written from a German standpoint and translated by Mrs. H. C. Conant); Clark's "Congregational Churches of Massachusetts;" Felt's "Ecclesiastical History of New England;" Cumming's "Dictionary of Congregational Usages and Principles;" Sawyer's "Organic Christianity of the Church of God;" Coleman's "Primitive Church;" Wellman's "Church Polity of the Pilgrims;" and Dexter's "Congregationalism."

CONGRESS, in international politics, an assembly of the sovereigns or plenipotentiaries of several states to determine questions and concert measures of common interest. The term is of modern origin, the earliest important European congress having been that of Münster and Osnabrück, which assembled in 1644, and concluded the peace of Westphalia in 1648. The subsequent congresses or conferences of most general interest have been those of the Pyrenees (1659), of Nimeguen (1676–'79), of Ryswick (1697), of Utrecht (1712–'13), of Aix-la-Chapelle (1748), of Teschen (1779), of Rastadt (1797–'99), of Erfurt (1808), of Châtillon (1814), of Vienna (1814–'15), of Aix-la-Chapelle (1818), of Carlsbad (1819) and Troppau (1820), of Laybach (1821), of Verona (1822), and of Paris (1856).—The term congress is also sometimes given to literary and scientific associations. It is also the designation of the combined senate and house of representatives which make the legislative branch of the government of the United States and the Spanish American republics, and of the house of representatives in the Spanish cortes.

CONGREVE, William, an English dramatist, born at Bardsey, near Leeds, in February, 1670, died in London, Jan. 19, 1729. He received his early education in Ireland, and proposed to study law, but applied himself to writing for the stage. His first comedy, "The Old Bachelor," was received with great favor at the Drury Lane theatre in 1693. In the following year appeared "The Double Dealer;" in 1695, "Love for Love;" and in 1697, his tragedy of "The Mourning Bride." The opening line of the latter, "Music hath charms to soothe the savage breast," has often been quoted; and Dr. Johnson considered the description of a cathedral which occurs in the play as the most poetical in the whole range of the English drama. His writings have been severely censured for their licentiousness; but his comedies abound in witty dialogue and lively incident; they secured for him a high reputation, and the admiration of Dryden and of Pope, the latter of whom dedicated to him his translation of the Iliad. Disappointed at the unfavorable reception of his last comedy, "The Way of the World" (1700), and worried by a contest with Jeremy Collier in regard to the morality of the English stage, he became disgusted and ceased to write plays. The munificence of Lord Halifax had placed him in easy circumstances. He had appointments in the public service worth £600 a year, and afterward he obtained the office of secretary for Jamaica, which raised his emoluments to £1,200. He wished to forget that he was an author; and when Voltaire waited upon him while he was in London, and took occasion to compliment his works, Congreve said that he would rather be considered a private gentleman than an author. "If you had been merely a gentleman," retorted Voltaire, "I should not have come to visit you." He was on intimate terms with the duchess of Marlborough, to whom he bequeathed the bulk of his fortune, amounting to about £10,000; and she dedicated a monument to him, and showed her regard for him in the most eccentric fashion. He was interred in Westminster abbey, the pall being borne by some of the most distinguished noblemen of England. Besides plays, his works comprise a romance and miscellaneous poems. A fine edition of his complete works, printed by Baskerville, appeared in Birmingham in 1761, and several others subsequently; the latest of these, edited by Leigh Hunt (London, 1849), gave occasion for Macaulay's essay on "The Comic Dramatists of the Restoration." His comedies have been translated into French and German.

CONGREVE, Sir **William,** an English engineer, born at Woolwich, May 20, 1772, died in Toulouse, May 15, 1828. In 1804, being then an artillery officer, he invented the rocket known by his name, which was used for the first time against Boulogne in 1806. He rose to the rank of general of artillery, succeeded his father as superintendent of the royal laboratory at Woolwich, and was member of parliament successively for Gatton and Plymouth. He wrote an "Elementary Treatise on the Mounting of Naval Ordnance" (1812), and a "Description of the Hydro-pneumatic Lock" for sluices and canals (1815). He invented improved processes of manufacturing gunpowder, amalgamating metals, and printing bank notes, and gave some attention toward a new mode of propelling ships. It is said that, foreseeing a war in the East, he submitted to the British government two plans, the one to defend, the other to reduce Constantinople, according as England might side with or against the Turks. Having become implicated in some questionable financial operations, he retired to the continent, where he remained till his death.



CONI, or **Cuneo. I.** A province of Italy, in Piedmont, bordering on France and the provinces of Turin, Alessandria, Genoa, and Porto Maurizio; area, 2,755 sq. m.; pop. in 1872, 616,817. About one half of the surface is level and the rest hilly and mountainous. The Ligurian and Maritime, and in the west the Cottian Alps, extend down into the province. It is traversed by the southern affluents of the Po, the most important of which is the Tanaro. Among the chief products are wheat, maize, mulberries, hemp, rice, and silk. In the mountains considerable cattle breeding and mining are carried on. The province is divided into the districts of Alba, Coni, Mondovi, and Sa-

luzzo. **II.** A city, capital of the province, situated 1,500 ft. above the sea, near the junction of the Gesso and Stura torrents, 46 m. S. of Turin, with which it is connected by railway; pop. in 1872, 22,882. Coni was originally a city of refuge. About the year 1100 Boniface, marquis of Savoy, conquered the region and established there the marquisate of Susa, but was not able to repress the outrages of the neighboring barons. The people soon rose against them, razed their strongholds, and built a town upon the site of the present city, which they called the "new city of Cuneo." In the 16th century the place was strongly fortified, and afterward underwent many sieges. In 1800, after the battle of Marengo, the French dismantled the fortress, and converted its site into promenades, and the town is now defended only by a wall. The cathedral is the ancient sanctuary of the "Madonna del Bosco," but has otherwise little interest. The church of San Francisco, belonging to a Capuchin convent, dates from the 12th century. There is also a handsome town hall, and other public buildings, and a pleasant public walk at the junction of the Gesso and Stura. There are considerable manufactures of silk and cotton, and the city is an agricultural mart for the surrounding region. About 10 m. S. W., in the the Val di Gesso, are the mineral baths of Valdieri, a place of much resort.

CONIC SECTIONS, the name given to the sections formed by cutting a right cone by a plane. The term is also constantly used to denote the curves formed by the intersection of the cutting plane with the surface of the cone. If the plane be parallel to the base of the cone, the section is a circle, or through the vertex a point. If the angle between the cutting plane and the plane of the base is less than the angle between the side of the cone and the base, the section is an ellipse, or through the vertex a point. If the angle between the cutting plane and the plane of the base is equal to that between the side of the cone and the base, the section is a parabola, or through the vertex a straight line. If the angle between the cutting plane and the plane of the base is greater than that between the side of the cone and the base, the section is a hyperbola, or through the vertex a triangle. If we suppose two similar cones to be so placed that they touch each other only at their vertices, and their axes form one straight line, then in the case of the hyperbola the cutting plane will cut both cones, giving two curves, which however are generally regarded as two branches of one curve. The properties of the conic sections were investigated with great thoroughness by the ancient Greek mathematicians of the school of Plato. Four books by Apollonius of Perga on conic sections have come down to us in the original Greek, and three more in Arabic translations. They are wonderfully full and accurate, and have left comparatively little for modern geometers to do in the investigation of the properties of these curves. Conic sections were in his day merely speculative theories; but after the lapse of 18 centuries it was discovered by Kepler that the orbits of the planets are ellipses, and from that time nearly all the most brilliant applications of mathematics to natural science and to the practical arts have been possible only through the use of conic sections. What was pure geometrical speculation among the Greeks, has proved of much practical advantage to us, the inheritors of their knowledge. The curves are now generally treated by the methods of analytical geometry. Every conic section may be represented by an equation of the second degree, and conversely every equation of the second degree may be represented by a conic section. One of the best purely geometrical treatises on the subject is the "Conic Sections" of Prof. Jackson of Union college; and the most elaborate and at the same time clear and practical analytical treatise is the "Conic Sections" of Prof. Salmon of Dublin.

CONINGTON, John, an English author, born at Fishtoft, near Boston, Aug. 10, 1825, died there, Oct. 25, 1869. He knew his letters when he was fourteen months old, and could read for his own amusement at three and a half years. Before he was six years old he was well acquainted with the historical parts of the Bible, and at eight he could repeat a considerable portion of the Æneid. In 1836 he was sent to the Beverley grammar school, where he remained two years, and at the age of 13 he entered the school at Rugby under Dr. Arnold. He was here distinguished for his remarkable memory and excellent scholarship, and after a course of five years was matriculated at Oxford in 1843. In 1847 he became a fellow of the university, and devoted himself chiefly to the study of the classics. He left Oxford in the following year, and established himself in London as a student of law. But he could not transfer his interest in the ancient poets to jurisprudence, and the experiment proved a failure. After six months' trial he returned to Oxford, and resumed his favorite pursuits. During his stay in London he formed a connection with the "Morning Chronicle," and for a time became a regular contributor to that journal. In 1857 he published an edition of the "Choephoræ" of Æschylus, having previously edited the "Agamemnon," with a translation into English verse which he afterward suppressed. He had also collected the materials for an edition of the "Supplices," which he was prevented from compiling by the plan for editing Virgil in conjunction with Mr. Goldwin Smith, and his subsequent appointment to the chair of Latin. The first volume of the edition of Virgil, containing the Eclogues and Georgics, was published in 1858, Mr. Smith having retired from the joint editorship. In 1863 he published a translation of the Odes of Horace, which was followed by the Æneid in 1866, by the last 12 books of the Iliad in 1868,

and by the satires, epistles, and *Ars Poetica* of Horace in 1869, the last appearing at the time of his death. In 1872 was published his edition of the satires of Persius, with a translation and commentary. The version of the Æneid is in the octosyllabic measure familiar to the readers of Scott and Byron, and has acquired considerable popularity. An edition of Conington's "Miscellaneous Writings," edited by J. A. Symonds, with a "Memoir" by H. G. S. Smith, has been published in two volumes (London, 1872).

CONIUM, a genus of umbelliferous plants, of which *C. maculatum*, the poisonous hemlock, is the best known species. This is an erect, branching, biennial plant, from 2 to 5 ft. high, with a tap-shaped root, smooth hollow stem, fern-like leaves, greenish white flowers, and globular crenellated fruit. The leaves when bruised emit a peculiar and disagreeable odor. It is a native of Europe, and now grows wild

Conium maculatum.

in the United States. It was used in medicine in the time of Dioscorides, and in all probability was the poison with which Socrates was put to death. Its activity depends upon a volatile alkaloid, conia, which is a poison of extreme energy. This alkaloid is contained in the leaves and seeds. The most efficient preparations of the drug are a fluid extract from the immature seeds and the *succus*. The latter is expressed from the green leaves and preserved by the addition of alcohol. The extract and tincture from the dried leaves are inert or nearly so. In medicinal doses the root is quite inert, and is not poisonous even when taken in quantities like a vegetable at an ordinary meal. The symptoms observed after a full dose (3 to 5½ drachms of the British succus for a healthy adult) are giddiness, indistinctness of vision, and a feeling of weakness and languor. When poisoning takes place, the weakness becomes actual paralysis, which may cause death, with or without convulsions, by involving the respiratory muscles, the intelligence and sensibility being unaffected. The symptoms resemble those produced by woorara, the South American arrow poison, and are probably due to a similar condition, a paralysis of the motor nerves, especially of their terminations, the nervous centres being unaffected. Conium may be used in diseases characterized by excessive or irregular motor activity, such as convulsions from teething, chorea, shaking paralysis, whooping cough, and general nervous irritability. It seems also in some cases to have a decided effect in relieving pain. Observation has shown the notion that it will retard the progress of cancer to be unfounded. The alkaloid, conia, is rarely used in medicine. The dose of the fluid extract is 8 or 10 drops three times a day, increased to half a teaspoonful or more if necessary. The succus of the British Pharmacopœia may be given in similar doses.

CONKLING, Roscoe. See supplement.

CONNAUGHT, the westernmost of the four provinces of Ireland, comprising the counties Galway, Mayo, Roscommon, Leitrim, and Sligo; area, 6,614 sq. m.; pop. in 1841, 1,418,859; in 1851, 1,012,006; in 1861, 913,135; in 1871, 845,993, of whom 803,532 were Roman Catholics. It is extremely rugged and mountainous except in the central part, and abounds in magnificent scenery, but the soil is the most barren in Ireland. A great part of the land consists of bog. It is drained by the Shannon and its affluents, and by numerous rivers of less note, which mostly take their rise from lakes and flow into the ocean. The coast is broken by many bays and inlets. The population is almost entirely of Celtic race, and the Irish language is still extensively spoken. The moral and physical condition of the people is lower than in the other provinces; abject poverty prevails, and the population is steadily decreasing. Galway, Sligo, and Ballina, all seaports, are the chief towns.—Connaught was divided into counties by Queen Elizabeth in 1590.

CONNEAUT, a village and township on Conneaut creek, Ashtabula co., Ohio, 2 m. from Lake Erie, and near the border of Pennsylvania; pop. of the township in 1870, 3,010; of the village, 1,163. It is memorable as the landing place of the first settlers of northern Ohio in 1796, whence it is sometimes called the Plymouth of the Western Reserve. It has a good harbor, with a lighthouse, contains a number of churches, schools, &c., and is the centre of an active commerce. The surrounding country is extremely productive. The Lake Shore railroad passes through the village.

CONNECTICUT, one of the thirteen original states of the American Union, and the smallest of the present states in area except Rhode Island and Delaware. It derives its name from its chief river, the Connecticut, meaning in the original Indian language the Long river. It is bounded N. by Massachusetts, E. by Rhode Island, S. by Long Island sound, and W. by

New York. The northern line, as originally run, measured 88 m., viz., 41 m. E. of Connecticut river, and 47 m. W.; the eastern line, 45 m.; the western line, 72 m. by the indirect course near the southern extremity, or 68 in a direct line. The average length of the state is 86 m., and the average breadth 55 m. Its area is 4,750 sq. m. It lies between lat. 41° and 42° 3′ N., and lon. 71° 55′ and 73° 50′ W. The state contains 8 counties and 166 towns. Of the former, Hartford, New Haven, New London, and Fairfield were incorporated in 1666, Windham in 1726, Litchfield in 1751, Middlesex and Tolland in 1785. Four counties border on Massachusetts and four on Long Island sound. The cities are: New Haven, pop. in 1870, 50,840; Hartford, 37,180; Bridgeport, 18,969; Norwich, 16,653; Waterbury, 10,826; New London, 9,576; and Middletown, 6,923. Connecticut until 1873 had two capitals, Hartford and New Haven, the legislature meeting alternately at each; but in that year it was

State Seal of Connecticut.

after much discussion decided that Hartford should be the capital. Many of the boroughs and villages of the state are extensively engaged in manufactures and commerce. The chief of these are New Britain, Danbury, Willimantic, Clinton, Sharon, Meriden, Collinsville, Bristol, Salisbury, Naugatuck, Norfolk, Greenville, and Windsor Locks. Stamford, Norwalk, Guilford, and Stonington have considerable coasting trade.—The population of Connecticut in 1679 was 12,535; in 1756, 131,805; in 1762, 145,666; in 1774, 197,856; in 1782, 208,870. At subsequent decennial periods the population and the comparative rank of the state in the Union have been as follows:

YEARS.	White.	Free colored.	Slave.	Total.	Rank.
1790.....	232,374	2,808	2,764	237,946	8
1800.....	244,721	5,330	951	251,002	8
1810.....	255,179	6,453	310	261,942	9
1820.....	267,181	7,870	97	275,148	14
1830.....	289,603	8,047	25	297,675	16
1840.....	301,856	8,105	17	309 978	20
1850.....	363,099	7,693	..	370,792	21
1860.....	451,520	8,627	..	460,147	24
1870.....	527,509	9,668	..	537,454	25

Of the total population in 1870, 265,270 were males and 272,184 females; 423,815 were native born, of whom 344,254 were born in the state, and 113,639 foreign born. Of the foreigners, 10,861 were born in British America, 13,001 in England, 70,630 in Ireland, 3,238 in Scotland, 12,443 in Germany, and 820 in France. The density of population was 113·15 to a square mile. There were 114,981 families with an average of 4·67 persons to each, and 96,880 dwellings with an average of 5·55 persons to each. The increase of population from 1860 to 1870 was 16·8 per cent. The number of male citizens 21 years old and upward was 127,499. There were in the state 125,409 persons between the ages of 4 and 16 years; the total number attending school was 99,663; 19,680, 10 years old and upward, were unable to read, and 29,616 could not write. Of the latter 5,678 were of native and 23,938 of foreign birth; 12,374 were males and 17,244 females; 27,941 were white and 1,675 colored; 2,661 were from 10 to 15 years old, 2,923 from 15 to 21, and 24,004 were 21 and over, of whom 8,990 were white males, 13,683 white females, 627 colored males, and 704 colored females. There were 4 adults unable to write to every 100 inhabitants. The number of paupers supported during the year ending June 30, 1870, was 1,728, at a cost of $189,918. Of the total number (1,705) receiving support June 1, 1870, 1,237 were natives and 468 foreigners. The number of persons convicted of crime during the year was 450. Of the total number (430) in prison June 1, 1870, 278 were of native and 152 of foreign birth. The state contained 252 blind, 475 deaf and dumb, 772 insane, and 341 idiotic. Of the total population 10 years of age and over (425,896) there were engaged in all occupations 193,421 persons, of whom 159,460 were males and 33,961 females; in agriculture, 43,653, including 18,934 agricultural laborers, 23,704 farmers and planters, and 865 gardeners and nurserymen; in professional and personal services, 38,704, of whom 908 were clergymen, 15,104 domestic servants, 13,017 laborers (not specified), 391 lawyers, 680 physicians and surgeons, and 2,711 teachers (not specified); in trade and transportation, 24,720; in manufactures, mechanical and mining industries, 86,344, including 2,698 blacksmiths, 2,540 shoemakers, 7,130 carpenters and joiners, 9,057 cotton-mill operatives, 3,148 machinists, 4,515 mill and factory operatives (not specified), 1,279 sewing-machine factory operatives, and 4,499 woollen-mill operatives. According to the report of the state librarian to the general assembly, there were registered during the year ending Jan. 1, 1871, 13,136 births, an increase of 655 over the number registered in any previous year; ratio of births to the population 1 in 40·9. There were 105 illegitimate, 1 to each 125·1 births, and 141 plurality births. The number of marriages was 4,871, an increase of 117 over the previous year, the ratio being 1 in every 55·2 of the

population. The number of deaths was 8,895, or 1 to every 60·5 of population; ratio of males to females, 109·9 to 100. Of the total number of deaths, 2,012 resulted from zymotic diseases, 1,088 from diseases of the nervous organs, 1,913 of the respirative, 322 of the circulative, and 389 of the digestive.—The face of the country is diversified by hills and valleys, which intersect the state from N. to S. and present beautiful and constantly varying scenery. The surface is rugged; the several ranges of mountains, or rather hills, which traverse the state, are continuations of those found in the states lying northward. The most westerly of these ranges is the Housatonic, which is rather a succession of hills than a continuous range. The Green mountain range, extending from Vermont and Massachusetts, terminates 2 m. N. W. of New Haven. Between this range and the Connecticut river is the Mt. Tom range, terminating at East Rock, a short distance N. E. of New Haven. The Blue hills of Southington, a part of this range, are 1,000 ft. high, and are said to be the most elevated land in the state. A fourth range on the E. side of the Connecticut terminates at East Haven. Three extensive valleys extend N. and S. across the state, viz.: the Housatonic in the west, the Connecticut in the centre, and the Quinebaug in the east, all of which contain much fine agricultural land. The valley of the Connecticut varies in width from 10 to 16 m.—Connecticut has about 100 m. of seacoast on Long Island sound, from the mouth of the Pawcatuck river on the southeast to the mouth of the Byram on the southwest. The sound is 140 m. long and 24 m. wide in its broadest part, and is navigable by the largest ships. The coast is indented by numerous bays which afford excellent harbors, the chief of which are at New London, New Haven, Stonington, Bridgeport, and Saybrook. The first named, capacious, deep, and not liable to be frozen over in winter, is one of the finest harbors in the country. There are other convenient harbors at Mystic, Niantic, Clinton, Guilford, Sachem's Head, Branford, Milford, Black Rock, Southport, Saugatuck, Norwalk, Stamford, and Greenwich.—Most of the state is drained by three principal rivers, with their branches: the Connecticut in the central, the Housatonic in the western, and the Thames in the eastern part. Besides these, there are various small streams of limited extent, which flow into Long Island sound. Of these the Quinepiack, which rises between Farmington and New Britain and empties into New Haven harbor, is the largest, and the only one which extends half across the state. The Connecticut, the longest river in New England, has a southerly course as far as Middletown, where turning abruptly it flows S. E. to its mouth at Saybrook on Long Island sound. With its branches it drains the central part of the state, including all of Hartford co. except Southington and the S. E. part of Farmington, all of Middlesex co. except Killingworth, the western part of Tolland and the N. E. part of Litchfield co. Vessels drawing 8 ft. of water can ascend to Hartford, 50 m. from the mouth. The only considerable tributary of the Connecticut in the state is the Farmington or Tunxis river. This stream has a singular course. Rising in the highlands of Berkshire, Mass., it runs S. E. to the centre of Farmington, then turns N. in a sluggish stream with little fall 15 m. to Tariffville, where it turns S. E., breaks through the trap mountains, and flows into the Connecticut at Windsor. The natural outlet of this river is New Haven harbor; and at a trifling expense the stream might be turned into the Quinepiack river, as a considerable part of its waters were carried to New Haven by the Farmington canal. The E. part of the state is watered by the Thames and its affluents. Its head waters rise in Massachusetts, and its basin embraces all of Windham, most of Tolland, and nearly the whole of New London counties. It takes the name of the Thames at the junction of the Yantic with the Quinebaug at Norwich, to which place or to Allyn's Point it is navigable for steamboats and small vessels; and from its mouth to New London it forms the best harbor in the state. In the view of the first settlers, the locality corresponded so well with London in facilities for commerce, that they named the river the Thames and the place New London, looking to a future city, which was in fact the first incorporated in the state. Above Norwich the waters of the Thames take different names. The Shetucket unites with the Quinebaug in the upper part of that town, and the two streams which unite and form the Shetucket are the Willimantic and Hop rivers. Corresponding with the Thames in the eastern is the Housatonic in the western part of the state, which with its main branch, the Naugatuck, and their branches, waters all of Litchfield co. except the N. E. towns, the W. half of New Haven co., and the N. and E. part of Fairfield co. The Housatonic is navigable for small vessels to its junction with the Naugatuck at Derby. The whole northern and the larger part of the state is wholly drained by the three large rivers above mentioned. Numerous small streams fall directly into Long Island sound, the largest into New Haven harbor. Some of these afford water power for manufacturing purposes; and the broad mouths of most of them form numerous harbors along the coast. Considering the general course of the mountainous ranges through the state, bearing to the W. of S., there is something peculiar in the S. E. bearing of the principal streams. There is a marked correspondence in the courses of the Housatonic from New Milford to Derby, the Farmington from its entrance into the state to Farmington, and the Willimantic and Shetucket to their entrance into the Thames, and especially the Connecticut from Middletown into the sound, through an unnatural bed of primitive formation.—Several ranges of trap rock pass through the central valley of Con-

necticut, sometimes continuous, and sometimes in broken elevations, with mural fronts on their western sides, and gentle declivities on the eastern. In some instances small elevations of trap rock are found, which have broken through the granitic rocks, at short distances E. and W. of this secondary valley. They are arranged in dikes and ridges, mostly in one general range, with collateral branches, running centrally through the secondary formation, dividing it into two portions. The eastern commences at New Haven, passes easterly of East rock to Middletown, and thence follows the Connecticut river into Massachusetts. The western portion runs from New Haven through Farmington, to Northampton. This secondary region, with its borders, embraces valuable mineral resources. The rocks on the E. and W. borders, and underlying the trap, are the red sandstone, or freestone, so useful for building purposes; immense quantities of it are quarried at Portland, on the Connecticut, and shipped to New York. In Bolton, near the E. border of this section, is the celebrated quarry of Bolton stone, a micaceous slate, which splits smoothly and beautifully in thin strata, and is extensively used for flagging and other purposes. Copper is found in various parts of the trap range. The Simsbury mines, in the present town of Granby, which was once a part of Simsbury, were worked early in the history of the colony, and were rendered famous by being converted into a state prison, the first in the state. The Bristol copper mines are in the N. E. borders of Bristol, a short distance W. of the secondary section, and within two miles of the railroad. Lead mines, with a large percentage of silver, have at various times been worked in Middletown, especially during the revolutionary war, but as yet to little profit. Veins of sulphate of barytes (heavy spar) are found in the E. parts of Cheshire and Southington, and large quantities are quarried and used in the composition of paints. Between the trap ridges on the borders of Southington and Berlin is found hydraulic lime, from which are manufactured large quantities of water cement. There is a cobalt mine in Chatham. The country watered by the Thames and its tributaries is granitic and metamorphic in gentle swelling hills, capable of cultivation to their summits. The quarries and mines of the Housatonic valley form valuable sources of wealth. Extensive beds of hematite iron ore are found, especially in Salisbury and Kent; and the heavy iron works at the former place have long been celebrated. The valleys of the Housatonic and branches, especially N. of New Milford, contain immense beds of limestone of the best quality, for ornamental and useful purposes, for buildings and monuments, and for burnt lime. The mountains furnish cheap fuel for burning, and the quarries of limestone are easily worked. The quarries of New Preston in Washington furnish large blocks of pure white marble, of fine grain and firm texture, which is suitable for buildings, monuments, and ornamental purposes. The whole seacoast, except across New Haven harbor, is of primitive formation, and difficult of cultivation. Much of it is suitable for grazing, but it is the most valuable for the production of fruit and vegetables. Granite in great variety, with gneiss and mica slate, is extensively quarried for use as building materials, flagging, &c. The quarries in Haddam on the Connecticut, and in other places, are extensively worked. The mineral resources of the state have been but partially developed. Slate for tiling prevails, but to what extent or excellence is not yet well tested. A beautiful marble, some portions resembling the verd antique, is found in Milford and North Milford. Clay for the manufacture of bricks and pottery abounds, especially in the secondary region; and bricks are extensively manufactured through the valleys, and pottery in Hartford and vicinity. Materials for the manufacture of porcelain and crockery have been discovered. Fire-brick furnaces and crucibles are extensively manufactured in New Milford. The feldspar quarry of Middletown furnishes a pure material for porcelain ware. Mineral chalybeate springs, some of them slightly sulphurous, are found in various parts of the state, but the only one of note is in Stafford, which formerly was much resorted to.—The climate, though changeable, is remarkably mild and healthful. The seasons are more uniform than in the northern parts of New England, the temperature in winter and summer being less extreme. Observations covering a period of 20 years show the mean temperature in winter to be 29·92°, spring 46·41°, summer 69·27°, and autumn 52·86°; whole year, 49·62°; highest mean for any month, 75·80°; lowest, 19·97°; range, 55·83°. In 1870 the lowest temperature was 7° below zero in January; highest, 97° in July. The fall of rain and snow during the winter was 15·60 inches; spring, 12·26; summer, 9·54; autumn, 10·21. According to the mortality statistics of 1870, the chief diseases were consumption, which was the cause of 15·65 per cent. of the total deaths; cholera infantum, 7·46 per cent.; pneumonia, 6·29; typhus fever, 5·49; scarlatina, 3·22; and apoplexy, 2·25.—The soil is generally good; while much of it is fitted for cereal agriculture, the greater part is better adapted to grass growing. In the alluvial bottom lands exists a rich loam, seldom equalled for continuous tillage and productiveness, while much of the land in the valleys is composed of a diluvial, light sandy or gravelly soil, unproductive unless artificially fertilized. The mountain and hill sides afford excellent pasturage, and many portions of the state are noted for their dairy products. The mountainous regions, unfit for cultivation, furnish wood and timber for domestic uses, and for buildings and ships. A great variety of trees abound in the forests, the most common of which are oak, chestnut, walnut, butternut,

birch, beech, ash, elm, maple, poplar, basswood, whitewood, and cedar. Most of the hardy fruit trees adapted to the climate grow naturally, and are easily and profitably cultivated: the apple and pear in great varieties and perfection, the cherry, plum, quince, and formerly the peach; also, berry-bearing shrubs and plants, as the strawberry, raspberry, blackberry, whortleberry, barberry, cranberry, currant, gooseberry, &c. Most of these grow wild, but some of them are much improved by cultivation. The strawberry is an important article of production for the market, and grapes are cultivated. On the rich alluvial bottoms and highly manured uplands tobacco is extensively raised. Garden seeds are largely produced, especially in Wethersfield, and by the Shakers at Enfield. Hay is one of the most important crops of the state. From the nature of the soil and face of the country, meadows and pastures must ever be numerous and extensive. Away from the interval lands, the dairy and beef cattle are the most profitable for the farmer. According to the census of 1870, there were in the state 25,508 farms; the number of acres of improved land in the state was 1,646,752; unimproved, 2,224,085, of which 577,333 were woodland; value of farms, $124,241,382; of farming implements and machinery, $3,246,599; total amount of wages paid during the year, including value of board, $4,405,064. There were 34,935 horses, 190 mules and asses, 98,889 milch cows, 39,639 working oxen, 79,485 other cattle, 83,884 sheep, and 51,983 swine; value of all live stock, $17,545,038. The productions were 2,085 bushels of spring and 36,059 of winter wheat, 289,057 of rye, 1,570,364 of Indian corn, 1,114,595 of oats, 26,458 of barley, 148,155 of buckwheat, 13,038 of peas and beans, 2,789,894 of Irish and 867 of sweet potatoes, 8,328,798 lbs. of tobacco, and 254,129 of wool. The orchard products were valued at $535,954, and the produce of market gardens at $599,718; 27,414 gallons of wine were made, 6,716,007 lbs. of butter, 2,031,194 of cheese, and 6,253,259 gallons of milk were sold. Other products were: 563,328 tons of hay, 1,725 bushels of clover and 4,471 of grass seed, 1,004 lbs. of hops, 14,266 of maple sugar, 6,832 gallons of sorghum molasses, 1,326 lbs. of wax, and 32,158 of honey. The value of forest products was $1,224,107; of home manufactures, $53,297; of animals slaughtered or sold for slaughter, $4,881,858; total estimated value of all farm productions, including betterments and additions to stock, $26,482,150. During the past few years much attention has been given in Connecticut to pisciculture, and laws have been passed for the protection and restoration of the fishes in the various waters of the state. The design is to introduce into the state new varieties of well known and marketable fish, and also to supply a greater abundance of the best varieties existing there. Under the supervision of the commissioners of fisheries, the principal ponds and many of the rivers have been stocked with fish, chiefly black bass, shad, and salmon from Maine and Canada. The first experiment in the artificial propagation of shad in the Connecticut river was made a short distance below Holyoke dam, in July, 1867, when about 40,000,000 of young shad were put into the river. Since that date the commissioners have continued their efforts with success.—The manufactures of the state are more general, multifarious, and productive than those of any other people of similar means. The abundant water power furnished by the rivers of the state contributes largely to this result. Nearly all the inhabitants are directly or indirectly interested in some kind of manufactures. Much of the machinery used is the fruit of inventions and improvements by the manufacturers themselves, among whom may be mentioned the names of Whitney, Goodyear, and Colt. The ingenuity and inventive talent of the people of Connecticut have ever been remarkable. In 1872 the proportion of patents granted by the United States to the number of inhabitants was greater in Connecticut than in any other state, being one to each 829 inhabitants. According to the census of 1870, Connecticut ranked first among the states in the production of clocks, India-rubber and elastic goods, and hardware; next to New York in the production of sewing machines, and to New Jersey in silk goods; next to Massachusetts and Rhode Island in woollen goods, New York and New Jersey in hats and caps, and New York and Massachusetts in edge tools and axes; fifth in the production of cotton goods, and eighth in the total value of all products. Connecticut has almost monopolized the manufacture of clocks for the United States and for a large part of the civilized world. Of the total value ($2,509,643) of all the clocks made in the United States in 1870, $2,245,043 were made in Connecticut. Nearly half of all the India-rubber goods and more than half of all the hardware manufactured in the United States in 1870 were the product of Connecticut industry. In the manufacture of carriages Connecticut is also noted. The other most extensive manufactures are those of agricultural and mechanical implements, hats, leather, boots and shoes, paper, saddlery, cabinet furniture, combs, buttons, wooden ware, powder, glass, soap and candles, friction matches, silver and plated ware, jewelry, and distilled spirits. The total number of manufacturing establishments reported by the census was 5,128, using 711 steam engines of 25,979 horse power, and 1,988 water wheels of 54,395 horse power, and employing 89,523 hands, of whom 61,684 were males above 16, 20,810 females above 15, and 7,029 youth. The total amount of capital employed was $95,281,278; wages paid, $38,987,187; value of materials used, $86,419,579; of products, $161,065,474. The chief industries are shown by the following table:

INDUSTRIES.	Number of establishments.	Steam engines, horse power.	Water wheels, horse power.	Hands employed.	Capital.	Wages.	Materials.	Products.
Bleaching and dyeing	18	13	258	188	$150,100	$81,352	$2,541,985	$2,849,743

—The extensive seacoast and various harbors, together with the enterprising and hardy character of the men, are favorable to commerce and navigation. Besides the coasting trade, which is extensive, especially with New York, Connecticut is largely interested in foreign commerce. There are in the state five customs districts, of which the ports of entry are Fairfield, Middletown, New Haven, New London, and Stonington. The imports from foreign countries and domestic exports for the year ending June 30, 1872, were as follows:

PORTS.	Imports.	Exports.
Fairfield	$18,798	$4,490
Middletown	814	.....
New Haven	843,227	321,359
New London	255,352	106,711
Stonington	82,108	.....
Total	$1,200,299	$433,160

The principal articles of export were flour, manufactures of wood, provisions, and carriages. The vessels entering from and clearing for foreign countries, together with the vessels registered, enrolled, and licensed at the different ports, were as follows:

PORTS.	ENTERED.		CLEARED.		REGISTER'D, &c.	
	No.	Tons.	No.	Tons.	No.	Tons.
Fairfield	39	5,509	34	4,580	163	11,296
Middletown	1	201	..	....	151	18,694
New Haven	117	24,681	97	16,489	155	17,600
New London	28	4,616	25	3,878	197	20,878
Stonington	13	2,873	8	870	115	15,290
Totals	198	37,880	164	25,817	781	83,760

Besides these, 1,055 vessels of 584,715 tons engaged in the coasting trade and fisheries entered, and 498 of 553,361 tons cleared. Of the total number enrolled, registered, and licensed, 696 were sailing vessels, with a total tonnage of 55,339, and 68 were steam vessels, tonnage 25,047. Ship building is an important item of industry. During the year there were built in the state 26 sailing vessels, tonnage 1,550, and 10 steam vessels, tonnage 373. The fisheries of the state are carried on chiefly from Stonington and New London. In 1872, 69 vessels with a tonnage of 1,473 from the former place were engaged in the cod and mackerel fishery; from the latter, 100 vessels, tonnage 2,918, were engaged in the cod and mackerel fishery, and 19 vessels of 3,113 tons in the whale fishery. According to the census of 1870, 1,001 persons were engaged in fisheries, and the products for that year amounted to $769,799.—Connecticut has one mile of railroad to every 5·38 square miles of area, and to every 620 inhabitants. According to the report of the general railroad commissioners of the state made in May, 1873, there were 22 railroad companies, representing 1,268 m. of railroad wholly or partly in the state, of which 10 were dividend-paying. The total number of miles in operation was 1,163, of which 868 were in Connecticut. The aggregate chartered capital of these companies amounted to $44,344,550; amount of funded and floating debts, $43,273,492; cost of road and equipments, $74,074,037. Up to May 1, 1873, $35,460,117 of the capital had been paid in, of which 44 per cent. was held by 4,005 stockholders resident in Connecticut. The gross earnings of all the companies during the year amounted to $11,368,425, of which about 50 per cent. was from passengers. The net income was $3,169,902, of which $2,271,143 was paid in dividends, being 7·9 per cent. on the paid-in capital of the companies paying dividends. There were 10,134,633 passengers transported during the year. The railroads lying wholly or partly in the state were as follows:

RAILROADS.	TERMINI.	Capit'l stock.	Cost of road and equip. ment.	Commenced operations.	Length of road.	Length in operation in Conn.

The directors of every railroad company are required to make an annual report, under oath, of the condition, receipts, and expenditures of their respective roads, to the railroad commissioners, who in turn report to the general assembly. All companies incorporated since 1850 are required by law to erect fences on both sides of their tracks throughout the whole extent, except at places where the commissioners may deem fences unnecessary; also to furnish all passenger trains with connecting aprons between the platforms of the cars as a protection to passengers from accidents. The liability of companies for the loss of life of a passenger through negligence of the company is limited to $5,000.—In 1871 there were 66 savings banks, with an aggregate deposit of $55,297,705 40, an increase during the year of $7,392,871; whole number of depositors, 177,887; average amount due each depositor, $310; average amount of deposit to each person in the state, $90 40; amount of state tax paid, $351,897; United States tax, $105,164; market value of total assets, $58,619,779. In January, 1873, the number of savings banks had increased to 78, with assets amounting to $71,271,395, and deposits to $68,523,397, of which $21,864,553 had been received during 1872, while $16,058,992 had been withdrawn during the same period. The state contained 4 state banks, with an aggregate capital of $1,450,000, and a circulation of $31,406; 8 chartered trust companies and 3 organized under the joint stock law, with an aggregate capital of $2,263,890, and deposits amounting to $2,869,406; and 81 national banks, with an aggregate capital of $25,656,820, and circulation issued to the amount of $20,443,410. The whole number of fire insurance companies doing business in the state in 1873 was 98, of which 27 were Connecticut companies, 63 incorporated by other states, and 8 foreign companies. The Connecticut companies employ 564 agents in the state, and the other companies 802. The gross premium receipts on risks written in Connecticut in 1872 amounted to $1,682,449, and the losses to $535,433, making an average ratio in favor of the receipts of over three to one. The total of risks written in the state during 1872 amounted to $147,717,429. In 1873 there were 34 life and casualty insurance companies authorized to transact business in the state, with gross assets amounting to $254,392,070.—The constitution of Connecticut was adopted in 1818, but has since been amended. It provides that the legislative, executive, and judicial powers shall be kept distinct. The legislature shall consist of a senate and house of representatives, called the general assembly, and meet on the first Monday of May. The governor may call extra sessions. The house of representatives consists of two members from each town incorporated before 1785, whatever its size; and with few exceptions, each town incorporated since is entitled to only one. The present number of representatives is 237. The senate consists of not less than 18 and not more than 24 members, elected by districts which consist of counties or divisions of counties, the number and extent to be determined by the general assembly after each decennial United States census. The present number of districts and senators is 21. Senators and representatives are elected annually by a plurality vote; there is no limitation as to age. The members receive $3 a day for not more than 45 days of actual session, and 10 cents per mile for travel. The speaker of the house receives $5 a day. The governor, lieutenant governor, secretary of state, treasurer, and comptroller are chosen annually. The governor must be 30 years of age. A majority of all the votes is required for a choice; and if no choice is made by the people, the two houses of the general assembly in convention make a choice from the two having the high-

est number of votes. The salary of the governor is $2,000; lieutenant governor, *ex officio* president of the senate, $500; treasurer, $1,200; secretary of state and comptroller, $1,000 each. Connecticut has no attorney general or state law officer. The commissioner of the school fund and the state librarian are appointed by the legislature; the salary of the former is $2,000 and expenses, and of the latter $1,600. The secretary of the board of education is appointed by the board, and receives a salary of $3,000 and expenses. A majority vote in each house is sufficient to pass a bill over the governor's veto. The pardoning power is vested in the general assembly; the governor can only grant a temporary reprieve. The judicial power is vested in a supreme court of errors, superior court, courts of common pleas for certain counties, probate court, inferior courts for certain cities and boroughs, and justices of the peace. The supreme court of errors consists of a chief justice and four associates, who are also judges of the superior court. This court has general appellate jurisdiction, civil and criminal, in matters of law and equity brought before it by writ of error or appeal from the judgments and decisions of the superior court. The superior court consists of six judges, exclusive of those who are judges of the supreme court. It has general original jurisdiction, civil, criminal, and equitable, and hears appeals from inferior courts. In all trials for crime punishable by death, the court must consist of at least two judges, one of whom must be a judge of the supreme court. The judges of the supreme and superior courts are elected by concurrent vote of the senate and house of representatives for a term of eight years, but are disqualified by the constitution when 70 years of age; the salary of each is $3,500. They may be removed by impeachment or by the governor on address of two thirds of each house. There are four courts of common pleas, respectively for the counties of Hartford, New Haven, Fairfield, and New London. These courts have civil jurisdiction in law and equity in cases where the amount in controversy does not exceed $500, and in cases not criminal hear appeals and writs of error from justices of the peace. Each court of common pleas consists of one judge, who is elected annually by the general assembly, and receives a salary of $2,500. Probate courts are held in each district, of which there are more than 100 in the state, most of them embracing single towns. The judges are chosen annually by the people. Justices of the peace are chosen biennially by the people of the towns in which they reside. The state militia consists of four regiments and a company of light artillery, comprising a total of 149 officers and 2,234 enlisted men. All elections are by ballot. The annual election is held on the first Monday of April, and in May following, when the legislature meets, the officers chosen enter upon their duties. By the laws of the state every white male citizen of the United States, having attained the age of 21 years, and resided one year in the state and six months in the town where he offers to vote, and who is able to read any article of the constitution, is entitled to the privileges of an elector. Colored citizens are entitled to vote by virtue of the 15th amendment to the federal constitution. An amendment to the constitution must first be passed by the house of representatives, receive a two-thirds vote of each house the following year, and then be ratified by a popular vote. The penalty for murder in the first degree, arson causing death, and perjury with intent to take life, is death. The crimes of arson endangering life, rape, and maiming may be punished by imprisonment for life, and manslaughter by a fine of not more than $1,000 and imprisonment for not more than 10 years. The laws concerning divorce are regarded as very loose, the following being the grounds upon which divorce may be granted: adultery; fraudulent contract; wilful desertion for three years with total neglect of duty; seven years' absence without being heard from; habitual intemperance; intolerable cruelty; sentence to imprisonment for life; bestiality or any other infamous crime involving a violation of conjugal duty and punishable by imprisonment in the state prison; and any such misconduct as permanently destroys the happiness of the petitioner and defeats the purposes of the marriage relation. All real estate conveyed to a married woman for money, or other property acquired by her personal services during marriage, may be held by her to her sole and separate use. Personal property of the wife vests in the husband as trustee, and upon his death goes to her if living, or if dead to her devisees, legatees, or heirs at law, as though she had always been sole; the husband is entitled to the rents, profits, and interests. When abandoned by the husband, the wife may transact business, sue and be sued, as if sole, during such abandonment. The husband is not liable for debts of the wife contracted before marriage; but she may be sued as if sole, and levy made on her property. Married women may dispose of both real and personal property by will in the same manner as other persons; but in conveyances by deed the husband must join, except during abandonment, when the wife may convey by order of the superior court. Connecticut is represented in congress by four representatives and two senators, and is entitled to six votes in the electoral college.—The state debt in 1860 amounted to only $50,000, which had been borrowed from the school fund. From July 1, 1861, to Oct. 1, 1865, five issues of bonds were made, amounting in the aggregate to $10,000,000, and drawing 6 per cent. interest, payable semi-annually. This bonded debt has been steadily diminishing; the bonds outstanding April 1, 1873, amounted to $5,095,900. Deducting $738,078 cash in the

treasury, the debt of the state beyond its assets amounted to $4,357,822. The revenue of the state during the year ending April 1, 1873, amounted to $2,054,465, and the expenditures to $1,175,567. The chief sources of revenue and expenditure were as follows:

RECEIPTS.

Insurance department	$26,231 61
Interest on deposits	22,020 74
State tax from towns	785,888 77
Tax on telegraph companies	725 78

Total	$1,175,567 88

The assessed value of real estate, according to the census of 1870, was $204,110,500; personal estate, $221,322,728; total, $425,433,237; true value of real and personal estate, $774,631,524. In 1860 the assessed value of real estate was $191,478,842; personal estate, $149,778,134; total, $341,256,976; true value of real and personal in 1860, $444,274,114, and in 1850, $155,707,980. The total taxation not national in 1870 was $6,064,843, including $1,875,024 state, $20,113 county, and $4,160,706 town, city, &c. In 1860 the total taxation not national was $1,015,037.—The public institutions sustained wholly or in part by the state are the reform school, normal school, industrial school for girls, American asylum for the deaf and dumb, general hospital for the insane, retreat for the insane, school for imbeciles, Hartford hospital, soldiers' orphans' homes, and the state prison. The state reform school, for the instruction, employment, and reformation of juvenile offenders, is at Meriden, and is under the control of a board of eight trustees, one from each county. The cost of the building and farm of 163 acres was $115,000. Boys between the ages of 10 and 16 years may be sent here for crime by the several courts of the state for a term of not less than nine months and during minority; they may also be received by indenture from parents or guardians, without expense to the state, for a period of not less than six months. The inmates are required to devote 6½ hours a day to labor and 4½ to study. Since the opening of the school, March 1, 1854, 1,662 boys have been received; 152 were received during the year ending April 1, 1872, at which date there were 314 inmates. The institution is self-sustaining, the receipts in 1872 amounting to $840 more than the expenditures. The boys are employed in the chair shop, on the farm, and in domestic labor. A similar institution, the industrial school for girls, was formally opened at Middletown, June 30, 1870, and is now in successful operation. It will accommodate 70 girls. For its establishment $10,000 were appropriated by the state, $70,000 contributed by individuals, and 46 acres of land given by the town of Middletown. Up to April 1, 1873, 123 girls had been admitted and 34 discharged. The American asylum for the deaf and dumb in Hartford is the oldest institution of the kind in the United States, having been incorporated in 1816, and opened April 15 of the following year. The governors and secretaries of state of the several New England states are *ex officio* members of the board of directors. Upward of 2,000 pupils have been received into the institution since its organization. The whole number in attendance during 1872 was 290; greatest number at any one time, 248; average attendance during the year, 247; number of instructors, 15. Of those attending during the year, 59 were supported by Maine, 22 by New Hampshire, 19 by Vermont, 109 by Massachusetts, 10 by Rhode Island, 60 by Connecticut, 1 by New Jersey, and 10 by Friends. The number of pupils April 1, 1873, was 225, of whom 51 were from Connecticut. The asylum makes an annual charge of $175 to each pupil. In the several New England states legislative appropriations have been made in aid of indigent pupils desiring to attend the institution. The fund of the asylum, April 1, 1872, amounted to $339,228, mostly derived from an endowment of land by congress in 1819. Connecticut has no institution for the blind; but an annual grant of $3,000 is made by the state for the education of the indigent blind at the Perkins institution in Boston. The general hospital for the insane, incorporated by the legislature in 1866, is pleasantly situated at Middletown, on the banks of the Connecticut river. The buildings are of Portland freestone, and when completed will be 768 ft. in length, with accommodations for at least 450 patients. The total cost will be $525,000, exclusive of the land, which was given by the town of Middletown. Provision is made for four classes of patients: pauper, indigent, private, and insane convicts. The institution is under the supervision of a board of trustees, consisting of the governor *ex officio*, and one person from each of the eight counties in the state. During the year ending April 1, 1873, the average number receiving daily treatment was 264. At that date there were 271 inmates, including 217 pauper patients, 98 indigent, 12 private, and 9 insane convicts; 74 were admitted and 65 discharged during the year. The revenue

amounted to $79,793, and the total expenditures to $77,981. Up to April 1, 1873, 643 patients were admitted, of whom 116 were discharged recovered, 72 improved, and 91 stationary, and 93 died. The retreat for the insane in Hartford was incorporated in 1822, and has at various times received aid from the state and donations from individuals. The average number in this institution is about 250, who are maintained at an average cost of about $5 a week. Since its opening about 5,000 patients have been treated. According to the census of 1870, there were 772 insane in the state. The accommodations of the state not being sufficient for this number, some have been treated in the hospitals of neighboring states, while others have been unprovided for. A school for imbeciles has been established at Lakeville, in the town of Salisbury, which receives both state and private pupils. In 1873 the number of pupils was 50, of whom 20 were state beneficiaries. The number dismissed or improved since the opening of the institution has been 26 per cent. A commodious building has been erected with the $10,000 appropriated by the legislature in 1872, which will enable the institution to accommodate all of this unfortunate class for which the state may have to provide. The Hartford hospital was first opened Aug. 1, 1860, with accommodations for 44 patients; by the addition of wings to the main building, the institution now accommodates 100 patients. The whole cost of buildings and land (70 acres) was $188,495, of which $127,200 were contributed by individuals and $30,000 by the state, which has also made an annual grant of $2,000 toward defraying current expenses. The permanent fund of the hospital amounts to $153,500. Patients are received from the various towns of the state for a small compensation, while not a few are admitted free. A large number of Connecticut soldiers have been received and treated, for which the institution received from the state to March 1, 1871, $15,095 08. From the opening of the hospital to that date 2,239 patients received its benefits, at an average cost of $5 68. Of this number 1,596 recovered, 155 improved, 120 remained stationary, and 304 died; 1,097 were Americans, and 1,142 of foreign birth; 1,827 of temperate and 412 of intemperate habits. Their average time at the hospital was 8·3 weeks. During the year ending Feb. 28, 1871, 370 patients (246 males and 124 females) were under treatment. The receipts amounted to $19,443 63; disbursements, $19,854 90. There is also a hospital in New Haven, supported in part by the state. Two soldiers' orphans' homes for the education of children of deceased soldiers, situated at Mansfield and Darien, are under the charge of voluntary societies, aided by state appropriations. The number of children of this class in the state in 1871 receiving $1 50 weekly each for their support was 1,648. The state prison is situated at Wethersfield. The building was erected in 1827, contains 232 cells, and is inadequate to the requirements of the state. The construction of a new one has been recommended by a committee of the legislature. The mode of inflicting punishment on convicts is by confinement in dark and solitary cells, and by fetters and shackles. Punishment by the shower bath and "moderate whipping, not exceeding ten stripes for any one offence," though not prohibited by law, has been discontinued. Convicts are employed in making boots, rules, &c., and burnishing plated ware. Instruction is given in the common English branches. The library contains 1,165 volumes. The number of convicts March 31, 1873, was 175; 142 were Americans and 33 foreigners, 3 females, 40 colored, 14 under 20 years of age, and 13 over 50; 160 for first offence; 23 under sentence for life. The income for the year was $26,452, including $14,695 from shoe shops, $3,030 from wire shop, $2,220 from burnishing shop, $4,833 from rule shops, and $880 for boarding United States prisoners. The expenditures amounted to $24,941. The whole number of persons committed to the various jails during 1871 was 2,593, being 347 more than in the preceding year. The whole number confined April 1, 1871, was 289, being 24 fewer than on April 1, 1870. There were six homicides committed in the state during the year.—The improvements made within the past few years in the system of education in Connecticut have given a marked prominence to the common schools of the state. The supervision and control of the educational interests of the state were in 1865 intrusted to a board of education, consisting of the governor, lieutenant governor, and four members, one from each congressional district, appointed by the legislature. The board appoints its own secretary, who performs the usual duties of a superintendent of education. In 1868 the law providing for the levying of tuition or rate bills was repealed, and a system of free public schools established, each town being required to levy a tax sufficient, with existing school revenues, for the maintenance of free schools. By the act of 1870 each town is required to maintain free public schools for at least 30 weeks in the year, in every district in which the number of persons between the ages of 4 and 16 years is 24 or more, and for at least 24 weeks in every district in which the number of such persons is less than 24. Proprietors of manufacturing establishments are by law prohibited, under a penalty of $100 fine, from employing children under 14 years of age who have not attended school for at least three months in each year; they are further required to see that all persons employed by them are able to read and write and understand the elements of arithmetic. An amendment to the law is recommended by the board of education, in order to secure the actual attendance at school for at least three months each year of all the children relieved

from employment. There is no state school tax in Connecticut (though a tax of this kind has been recommended), the money for the support of common schools being derived from special funds and local taxation. The constitution directs that the school fund shall remain perpetual, and that the interest be used for the support and encouragement of common schools and for no other purpose. This fund, chiefly derived from the sale of the lands of the state in the Western Reserve, Ohio, amounted on Sept. 2, 1872, to $2,044,190. For the year ending March 31, 1873, the receipts amounted to $156,158; disbursements, $137,812; number of children returned, 132,924; rate of dividend per capita, $1. Owing to the increase of the number of school children, the fund is relatively diminishing. In 1863 the dividend per child was $1 20, and in 1873 it was $1. The town deposit fund amounts to $763,661; revenue, $45,650. During the first year of the free schools there was an increase in attendance of more than 6,000 over the increase in enumeration, while it is evident that not fewer than 10,000 children were prevented from attending school under the rate-bill system. The average school year has advanced to 8 months and 12½ days, making it longer than the school year in most of the other states of the Union. In 1872, of the children of school age, 95·23 per cent. were attending schools. There were 1,535 school districts in the state, and 1,630 public schools, taught by 2,420 teachers, of whom 1,721 were females. The number of children between the ages of 4 and 16 years was 131,748, of whom 122,342 attended school; 113,588 were registered in the public schools, and 8,754 in private schools; and 3,541 persons over 16 years of age were registered in the public schools. The total amount expended for public schools during the year (including $833,759 for teachers' salaries, $370,369 for new school houses, and $70,005 for repairs) was $1,496,980, being an advance of $218,154 beyond the expenditure of any former year for this purpose. The total amount received from all sources for public schools was $1,503,617, including $128,468 revenue of school fund distributed Feb. 28, 1871; town deposit fund, $45,167; income of local school funds, $9,627; town tax, $641,837; district tax, $410,708; voluntary contributions, $11,012; other sources, $256,796. The amount raised for each child enumerated was $11 70, while in 1871 it was $11 83. In addition to the public schools, there are other free schools supported by individual liberality, or by the income of invested funds. Among these are the day and evening schools maintained at Manchester by the Cheney brothers, at an annual expense of $3,400; Bacon academy at Colchester, with a fund of $25,000, free to the inhabitants of that place; Norwich free academy, with a fund of $90,000; and the Hopkins grammar school in New Haven. Since 1867 evening schools have been maintained as a part of the free public school system, with the most satisfactory results. The experiment was first made in New London, and its success led to the establishment of similar schools both for boys and for girls in several of the cities and larger villages. In six of these schools situated respectively in New London, Hartford, New Haven, Birmingham, and Bristol, the average length of the session of 1870–'71 was 15 weeks; average number of pupils, 593. The state normal school at New Britain was established by the legislature in 1849, and opened in May of the following year. It was under the charge of a board of eight trustees, one from each county, till 1865, when it was transferred to the supervision of the state board of education. After suspension for two years on account of the withdrawal of the appropriation by the legislature, it was reorganized in 1869. The annual appropriation for this school is $7,500. The expenses for 1872 were $9,655; number of instructors, 5; pupils in attendance, 148, of whom 130 were females; average age of pupils, 20 years and 2 months. The whole number of pupils connected with the school since its organization is 2,628, at an average cost to the state of less than $40 each. Teachers' institutes are held in the different counties under the direction of the secretary of the board of education, for which purpose a sum not exceeding $3,000 per annum may be drawn from the state treasury. During 1870–'71, 33 teachers' institutes were held, attended by 2,286 teachers and school officers. The total expenditures amounted to $2,999, including $2,483 for 289 lectures. Connecticut has three colleges, three theological schools, one law, one medical, and one scientific school. The total number of volumes in the libraries of these institutions is 142,750. There are 25 academies and seminaries (of which 4 are exclusively for females), with more than 100 instructors and 1,404 pupils, of whom 685 are females, and libraries containing 6,185 volumes. In addition to these there are four seminaries for the superior instruction of females exclusively, with 27 instructors, 198 pupils, and 1,750 volumes in their libraries. Yale college (Congregational), in New Haven, was established in 1701, and in 1873 had 73 instructors, 904 students in all departments, and 90,000 volumes in the library. Connected with it are a theological seminary, law school, school of fine arts, and the Sheffield scientific school. The last named institution has received the proceeds realized by the sale of the scrip for 180,000 acres of land granted to Connecticut under the act of congress of 1862, known as the agricultural college bill. The state holds four scholarships in the Sheffield scientific school. Six seats in the board of corporation, previously occupied by the six senior senators in the state legislature, were transferred to the alumni in 1872. Trinity college (Episcopal) was established in 1823 at Hartford, and in 1872 had 16 instructors, 163 students, and a library of 15,000 volumes.

Wesleyan university (Methodist), at Middletown, was established in 1831; number of instructors, 10; students, 163; volumes in library, 20,000. The theological institute of Connecticut (Congregational), established in 1834 at East Windsor, and subsequently removed to Hartford, has 3 professors, 25 students, and 7,000 volumes in library; whole number of alumni, 290. The theological department of Yale college (Congregational), organized in 1823, has 7 professors, 55 students, and 865 alumni; amount of endowment, $308,000. Berkeley divinity school at Middletown (Episcopal), organized in 1855, has 10 professors, 38 students, and 149 alumni; endowment, $40,000. In 1866 the number of students in the colleges and professional schools of the state was 883; in 1867, 946; in 1868, 960; in 1869, 1,016; in 1870, 1,037; in 1871, 1,048. Of the latter, 179 were inhabitants of Connecticut, and 69 Connecticut students in 1871 were in colleges of other states. There are public libraries in 64 towns, which receive state aid under the act of 1856 providing for state library appropriations. The principal libraries of the state, exclusive of those connected with colleges, &c., number 13, and contain 66,280 volumes. According to the census of 1870, the total number of libraries was 63, having 285,937 volumes. These included the state library, with 12,000 volumes; 5 school, college, &c., with 142,000 volumes; 1 historical and scientific, with 14,000; and 56 circulating, with 117,937. The number of newspapers and periodicals was 71, with an aggregate circulation of 203,725; copies annually issued, 17,454,740. Of these there were 16 daily, circulation 35,730; 1 semi-weekly, circulation 800; 43 weekly, circulation 107,395; 2 semi-monthly, circulation 900; 7 monthly, circulation 56,400; 1 bi-monthly, circulation 1,150; and 1 quarterly, circulation 1,350.—In 1870 the state contained 826 religious organizations, having 902 edifices, with 338,735 sittings, and property valued at $13,428,109. The statistics were as follows:

DENOMINATIONS.	Organiza'ns.	Edifices.	Sittings.	Property.

—The Connecticut river and the seacoast adjacent to its mouth were first explored by the Dutch from New Netherlands, who laid claim to the territory. The counter claim of the English was based upon the patent of Connecticut granted in 1631 to Lord Say and Seal, Lord Brooke, Sir Richard Saltonstall, and associates, by the earl of Warwick, to whom with others the first patent of New England had been granted by James I. in 1620. In 1633 the Dutch made a settlement at Hartford, but in a few years sold out to the English. Early in 1636 permanent settlements were made at Hartford, Windsor, and Wethersfield, by companies from Massachusetts, bearing a commission from the general court of that colony investing certain of their number with legislative and judicial power to govern the new plantation. The first court was held April 26, 1636, at Hartford. In the following year the three towns organized themselves into an independent government for self-protection against the Pequots, declared war against that tribe, and completely annihilated its power. In 1638 New Haven was settled by a distinguished company of emigrants from England who had landed at Boston the preceding year. The peculiar feature of the civil polity adopted by them was that all civil power should be vested in members of the church. A constitution for the government of the colony of Connecticut was perfected and approved by a general vote of the people, Jan. 14, 1639; the first example in history of a written constitution organizing a government and defining its powers. It formed the basis of the charter of 1662, and its leading features have been copied into the constitutions of the several states and of the United States. After stating that the word of God requires human governments, and that the object of such governments is to maintain and preserve the moral and civil welfare of the people, it makes provision for the three departments of government, the legislative, judicial, and executive, which were all to be filled by persons to be appointed by and to derive their power from the people. The freemen (and all might be made freemen who had been admitted inhabitants by the towns themselves) were to meet annually in April, at a court of elections, for the choice of so many magistrates and other public officers as should be found requisite, one of whom was to be designated as governor. All elections were by ballot. The governor was voted for first, and elected by a plurality vote; then the magistrates, subsequently called assistants, were voted for in a similar manner. The governor, or executive, sat with the magistrates in their judicial capacity, and both the governor and magistrates sat with the deputies elected by the several towns in a legislative capacity. As the deputies constituted a majority of the general assembly, the legislative power was substantially in the hands of the people, while the governor and magistrates could advise as to neces-

sary legislation. As there were to be two sessions of the legislature annually, one in the spring, called the court of elections, and the other in the fall, for enacting laws and other public services, the towns chose their deputies semi-annually. In this constitution, and in the subsequent administration of it till 1661, there is no recognition of any higher human power than the people, and practically Connecticut was an independent government. But when Charles II. came to the throne, fears began to be entertained for the future, and the general court determined to make a formal avowal of their allegiance to the crown and apply for a charter. This charter, embracing the colonies of Connecticut and New Haven, was obtained in 1662, and the union between the colonies was completed in 1665. The charter granted the colony jurisdiction over the lands within its limits; provided for the election of a governor, deputy governor, and 12 assistants, and two deputies from each town, substantially the same as provided for under the previous constitution; allowed the free transportation of colonists and merchandise from England to the colony; guaranteed to the colonists the rights of English citizens; provided for the making of laws and organization of courts by the general assembly, and the appointment of all necessary officers for the public good, the organization of a soldiery, providing for the public defence, &c. This charter was of so general a character, and conferred so large powers, that no change was necessary when Connecticut took her stand as one of the independent states of the Union, on the declaration of independence in 1776; and it continued, without alteration, as the constitution of the state till 1818, when the present constitution was formed. Until 1670, at the general election, all the freemen assembled at Hartford and personally voted for the state officers and assistants. Thereafter they voted by proxy or sent up their votes. In July, 1685, a writ of *quo warranto* was issued by the king's bench, and served on the governor and company, with the design of taking away the charter and uniting the New England colonies in one government under a royal governor. Sir Edmund Andros arrived in Boston, Dec. 19, 1686, with his commission as governor. In October, 1687, he came to Hartford while the assembly was sitting and demanded the charter. According to current history, it was produced and laid upon the table, but was subsequently seized and concealed in the famous charter oak. (See Andros, Sir Edmund.) Andros seized the government, which he administered, or rather it was administered under him, in a very oppressive manner. On the dethronement of James II., and the consequent deposition of Andros, the government, on May 9, 1689, resumed its functions as if the period since the usurpation of Andros to that time were annihilated; and as the charter had not in the king's court been declared forfeit, it was after a struggle allowed to continue in force, the freest constitution ever granted by royal favor. Until October, 1698, the general assembly constituted but one house, consisting of the governor, assistants, and deputies, over which the governor presided, and the secretary of state was clerk. At that session the governor and assistants, or council, were constituted the upper house, and the deputies from the several towns the lower house, with power to appoint their own speaker and clerk. Every bill must pass both houses before it could become a law. Soon after this separation of the general assembly into two bodies, the superior court was constituted a distinct judicial body. From the union of the colonies till 1701 the general court had met in Hartford. Thereafter it was ordered that the May session should be held in Hartford and the October in New Haven. While the early laws of Connecticut were in general liberal and enlightened, it is not denied that many extreme penalties were prescribed by the early statutes. There were twelve offences punishable with death, while there were severe laws against Baptists, Quakers, witchcraft, &c. The authenticity of the code commonly called the blue laws of Connecticut is denied by the best authorities. During the revolutionary struggle no other state in the Union furnished so many men according to its population, or so much aid according to its means, as Connecticut; and Gen. Washington had no coadjutor more efficient than Jonathan Trumbull (Brother Jonathan), governor of Connecticut. On June 14, 1776, twenty days before the declaration of independence, the general assembly of Connecticut unanimously instructed their delegates in congress to propose to that body "to declare the united American colonies free and independent states, absolved from all allegiance to the king of Great Britain." The whole number of soldiers enlisted in Connecticut during the civil war was 54,882, being equivalent to 48,181 men for three years. There were 2,340 enlistments for three months, 5,602 for nine months, 529 for one year, 25 for two years, 44,556 for three years, 26 for four years, and 1,804 not known. The organizations were 30 regiments of infantry, 2 of heavy artillery, 2 light batteries, 1 independent battery, and 1 regiment and 1 squadron of cavalry. During the war 1,094 men and 97 officers were killed in action; 666 men and 48 officers died from wounds; 3,246 men and 63 officers died from disease; and 389 men and 21 officers were missing. (See supplement.)

CONNECTICUT RIVER, the largest river of New England, rises on the borders of New Hampshire and Canada, and flows southerly into Long Island sound at Saybrook, Conn., in lat. 41° 16′ 15″ N., and lon. 72° 21′ W. It was called by the Indians Quonektacat, signifying Long river, and has always been noted for its beauty. It rises by two head streams near the N. boundary of Coös co., N. H., 1,600 ft. above the sea, flows within a few miles through

Second and Connecticut lakes, and receives several small tributaries, one of which separates New Hampshire from Canada on the west. From Connecticut lake it flows W. and S. W. to a point near the N. E. angle of Vermont, whence it forms the boundary line between that state and New Hampshire, flowing generally S. S. W. It afterward flows S. across the W. part of Massachusetts and through the centre of Connecticut to Middletown, where it turns S. E. and flows to the sound. The length of the river is more than 400 m. Its width at the N. boundary of Vermont is about 150 ft., which increases to about 390 ft. within 60 m., and varies from 450 to 1,050 ft. in Massachusetts and Connecticut. The Connecticut is navigable to Middletown, 30 m., for vessels of 10 ft. draught, and to Hartford, 50 m., for those drawing 8 ft. There are numerous falls in the river, the chief of which are the Fifteen-mile falls in New Hampshire and Vermont, the White river falls below Hanover, Bellows Falls, those at Montague and South Hadley in Massachusetts, and at Enfield in Connecticut. These falls afford abundant water power. By means of canals around them, the river has been made navigable for boats of 8 or 10 tons burden as far as Newbury, near the mouth of Wells river in Vermont, 270 m. from the sound. The principal tributaries of the Connecticut are: from the west, the Passumpsic, Wells, White, and Williams in Vermont, the Deerfield and Westfield in Massachusetts, and the Farmington in Connecticut; from the east, the Ammonoosuck in New Hampshire, and Miller's and Chicopee in Massachusetts. Above Hartford the Connecticut is spanned by numerous bridges. Great efforts have been made recently for the artificial propagation of shad and salmon in the Connecticut river, where they formerly abounded. As a result, numerous shad have been caught, but the experiment has proved less successful in regard to salmon. The Connecticut valley is about 300 m. long, with an average width of 40 m.; it contains valuable agricultural lands and much highly attractive scenery.

CONNEMARA, a district forming the W. part of county Galway, Ireland, about 30 m. long and 20 m. broad, celebrated by its wild and picturesque scenery. (See GALWAY.)

CONNER. See PERCH.

CONNER, David, an American naval officer, born in Harrisburg, Pa., about 1792, died in Philadelphia, March 20, 1856. He entered the navy as midshipman in January, 1809, and as acting lieutenant took part in the action between the Hornet and Peacock, Feb. 24, 1813. The Peacock surrendered in a sinking condition in 15 minutes after the engagement commenced, and Lieut. Conner was charged with the duty of removing the prisoners, most of whom he succeeded in saving, though not without losing three of his own men. In 1813 he became a lieutenant, and remained in the Hornet, under the command of Capt. James Biddle. In the action with the Penguin in 1815 he was dangerously wounded. For his gallant conduct in that action he was presented with a medal by congress, and the legislature of his native state voted him a sword. On March 3, 1825, he was promoted to the rank of commander, and on March 3, 1835, to that of captain. At the opening of the war with Mexico he was in command of the squadron on the West India station. In May, 1846, having received intelligence that Arista had determined to attack Gen. Taylor, he sailed from Vera Cruz for Brazos Santiago, where he arrived on the 8th, too late for the fighting. He now established an efficient blockade of the Mexican ports on the gulf. In August and October two fruitless attempts were made to enter the port of Alvarado. On Nov. 14 the port of Tampico was captured. On March 9, 1847, he directed the landing of the army under Gen. Scott at Vera Cruz, but was soon after compelled by ill health to return home. His last service was the command of the Philadelphia navy yard.

CONOLLY, John, an English physician and author, born at Market Rasen, Lincolnshire, in 1795, died at Hanwell, March 5, 1866. He graduated at the university of Edinburgh in 1821; was professor of medicine in the university of London from 1828 to 1831, and consulting physician to the lunatic asylum at Hanwell from 1839 to 1843, and to that for idiots at Earlswood. He acquired distinction by his adoption of the system of non-restraint in the treatment of the insane. He invited Dr. Guggenbühl to England, and after examining the institution for cretins near Interlaken and the schools of Seguin and Voisin in Paris, he procured the establishment of the temporary school for idiots at Colchester and of the royal asylum at Surrey, of both of which he became an active manager. Besides contributions to current medical literature, he published "Inquiry concerning the Indications of Insanity" (1830), "Construction and Government of Lunatic Asylums" (1847), "Treatment of the Insane" (1856), and "Study of Hamlet" (1863).

CONON, an Athenian general and admiral, living about 400 B. C. In 413 he commanded a fleet of 18 ships off Naupactus, to prevent the Corinthians from sending aid to the Syracusans; in 409 he was elected general in connection with Alcibiades and Thrasybulus; and in 407 he was made the chief of the ten generals appointed to supersede Alcibiades, whose dissolute conduct and mismanagement had disgusted the Athenian people. Soon after, in an engagement with the Spartan admiral Callicratidas, off Mitylene, he was defeated with the loss of 30 vessels, and was compelled to take refuge with the remnant of his fleet in the harbor of that city, where he was closely blockaded by his opponent till the Athenian victory at Arginusæ effected his deliverance. Having been soon after appointed, with five colleagues, to the command of a large fleet, he proceeded at once to the Hellespont to engage the Lace-

dæmonian squadron, under the command of Lysander, but was surprised at Ægospotami (405), and sustained that memorable defeat which placed Athens at the mercy of her great rival. How far he was responsible for this disaster it is not easy to determine, but that his colleagues were shamefully remiss in duty there is no doubt. He was the only Athenian general on his guard, and, with the division under his command, escaped to his friend Evagoras, king of Cyprus, where he remained eight years. In 395, having repaired in person to the Persian court to offer his services to Artaxerxes II. against the Spartans, he was appointed with Pharnabazus to the joint command of a powerful fleet, with which, in August, 394, he gained a splendid victory over Pisander at Cnidus. The next year Conon and Pharnabazus sailed for the Peloponnesus. After they had laid waste the coast of Laconia, Conon repaired to Athens, and rebuilt the walls and fortifications both of the city and of the Piræus. Thus he had the satisfaction at last of being hailed by his countrymen as at once the deliverer and the restorer of the city. Having been subsequently sent by the Athenians on an embassy to Tiribazus, satrap of Ionia, to oppose the intrigues of Antalcidas, who was endeavoring to negotiate a general peace under the mediation of Persia, he was seized in violation of public faith, and thrown into prison. According to some accounts he was put to death, but it is more probable that he escaped to Cyprus and there spent the rest of his days. The public life of Conon was one of the purest and most useful, as well as one of the most eventful, that adorn Athenian annals.

CONRAD. I. Duke of Franconia, elected king of Germany in 911, when the male line of descendants of Charlemagne had become extinct, died Dec. 23, 918. The royal authority had been so much shattered under the feeble rule of his predecessors that his brief reign was only a series of campaigns against his disobedient vassals. He was unsuccessful in his efforts to reconquer Lorraine from France, and to subdue Duke Henry of Saxony; but in Swabia he overcame two lords who had broken the public peace and had them tried and executed. He also expelled Arnulf, the seditious duke of Bavaria, who however took revenge by inciting the Hungarians against Germany. They invaded the empire and carried destruction to the borders of France. Conrad died from a wound received in battle with them, and on his deathbed entreated his subjects to elect his former adversary, the duke of Saxony, his successor. **II.** King of Germany from 1024, and emperor of the Romans from 1027, died at Utrecht, June 4, 1039. He was one of the wisest and most energetic among the rulers of Germany. Immediately after his election he visited all the provinces of the empire, establishing law and order with a powerful hand. He proclaimed the *treuga Dei* (truce of God), and endeavored to base the imperial power more immediately upon the lower nobility, that is to say, upon the people, since at that time the middle and lower classes were not yet thought of in politics. In 1026 he went to Italy, chastised the seditious vassal princes and municipalities, confirmed the rule of the Normans in southern Italy, and was crowned Roman emperor by the pope. Having restored peace and order throughout Italy, he returned to Germany, suppressed a rebellion instigated by Ernest of Swabia, repelled the Hungarians who attempted to wrest Bavaria from the empire, conquered Burgundy, and defeated the Poles, who made inroads into eastern Germany. While his son Henry subdued the Slavs, who had invaded northern Saxony, Conrad went once more to Italy, where the imperial authority was again defied by the nobles and clergy (1036). He was only partially successful, and was compelled to raise the siege of Milan, after which he returned to Germany. He was succeeded by his son Henry III. **III.** King of Germany, a son of Frederick of Swabia, born in 1093, died at Bamberg, Feb. 15, 1152. At the age of 20 he distinguished himself in the defence of the emperor Henry V. against his enemies. Returning from a pilgrimage to Jerusalem, he found Lothaire, elected by the Guelph party, upon the imperial throne, against whom he was in 1128 crowned king by the Lombards, but was ultimately defeated, excommunicated, and his coronation declared null. Still his courage and frankness, perhaps also apprehensions of the overshadowing power of the Guelphs, obtained for him many friends among the German princes, and after Lothaire's decease (1137) he was elected king (1138). He now turned against his rival, Henry the Proud, duke of Bavaria and Saxony, and wrested Bavaria from him, but left him in possession of Saxony. The attempts of Henry's brother, Guelph IV., to reconquer Bavaria, were frustrated by Conrad. In the mean time the Italian municipalities had risen against the papal power, and Conrad was invited by both parties to aid them. Distrusting the friendship of the Italians, he declined to do so, nor was he tempted by the offer of the imperial crown. A crusade which he undertook, jointly with Louis VII. of France, was unsuccessful. He was defeated at Iconium in 1147, and compelled to desist from his attempts to conquer Damascus and Ascalon. When he returned to Germany, in 1148, he found disorder reigning supreme. The Guelphs, allied with the Norman king, Roger of Sicily, had once more tried to reconquer Bavaria; in Poland the legitimate duke Ladislas II. required Conrad's assistance against his own brothers; and Italy once more urged upon him the necessity of his presence. While preparing for a campaign in Italy, he suddenly died, probably poisoned by agents of King Roger. **IV.** King of Germany, born in Apulia in April, 1228, died at Lavello, May 21, 1254. The son of the emperor Frederick II., he was crowned king of the Romans in 1237, and succeeded his

father as king of Germany in 1250. With great energy he contended against the intrigues of the pope and the usurpations of his tools among the German princes, repulsed the Mongols who had invaded the empire, and succeeded in putting down his father's rival, Henry Raspe of Thuringia, set up by the pope (1247). But both before and after his accession he had to contend with a new rival king, William, count of Holland; and though in spite of defeat he maintained himself upon the throne, the prestige of his power was lost. Embarrassed by the increasing anarchy in Germany, he went to Italy in order to save at least the Apulian kingdom (1251). He subdued it once more, and conquered Naples; but the enmity of the pope, who had excommunicated him, foiled his efforts to reëstablish the imperial authority. He fell a victim to a lingering disease, occasioned as was supposed by poison, leaving only an infant two years of age (Conradin) as the last heir of the dynasty of Hohenstaufen.

CONRAD, Karl Immanuel, a German architectural painter, born in Berlin, March 30, 1810. He studied in Berlin, and was a teacher of his art as early as 1830, soon producing many fine works. He subsequently applied himself, under the direction of Schadow at Düsseldorf, to the Romanesque and Gothic styles of art, and has executed many pictures of churches and other edifices. His masterpiece, representing the cathedral of Cologne, was painted in 1842 at the request of the king, and he made an enlarged copy of it, which was presented by the diocese of Cologne to Pius IX. on the 50th anniversary of his ordination as priest. He visited Belgium and France in 1845, England in 1851, and Italy in 1869. He has painted views of London, Windsor castle, Rome from the Pincio, and a picture of the pope's private apartments in the Vatican. In 1871 he was employed on a painting of the interior of the cathedral of Cologne. He excels in etching.

CONRAD, Robert T., an American jurist and author, born in Philadelphia, June 10, 1810, died June 27, 1858. While studying law, he wrote his first tragedy, "Conrad of Naples," which was produced successfully in the principal theatres of the country. Admitted to the bar at an early age, he became connected with the press, and after other editorial labors began in 1832 the publication of the "Daily Intelligencer" newspaper, which was subsequently merged in the "Philadelphia Gazette." He was obliged by ill health to abandon the labors of daily editorship, resumed the practice of law in 1834, and was appointed recorder of the recorder's court in 1835, judge of the court of criminal sessions in 1838, and of the court of general sessions in 1840. He afterward resumed practice as an advocate, and was editor of "Graham's Magazine," contributor to the "North American," president of a railroad company, and mayor of Philadelphia. While attending to his duties on the bench, he wrote the tragedy of "Aylmere," the hero of which is Jack Cade, who takes the name of Aylmere while in exile in Italy, and is represented as a democratic patriot. He wrote another tragedy, "The Heretic," which has not been acted or published. A volume appeared from him in 1852, under the title of "Aylmere, or the Bondman of Kent, and other Poems." The principal of the additional poems are "The Sons of the Wilderness," composed of reflections on the fate of the Indians, and a series of sonnets on the Lord's prayer.

CONRADIN, the son of Conrad IV., duke of Swabia, and the last of the Hohenstaufen, born in 1252, beheaded Oct. 29, 1268. His father dying while he was an infant, he resided sometimes in the court of Louis of Bavaria, and at other periods under his protection at the castle of Ravensburg. He formed an intimate friendship with Frederick, son of the margrave of Baden, and, on the death of Manfred, who had acted as his regent and subsequently usurped the crown in the Apulian possessions, accepted the invitation of the Italian Ghibellines to place himself at their head. The greater part of the possessions of the Hohenstaufen had been swept away, and his stepfather, Meinhard II. count of Görz, watched every opportunity to seize the remaining inheritance of the family; for Conradin was yet duke of Swabia, and held the ancient Franconian possessions of the Salic emperors. He was aided in his determination by Meinhard and Louis of Bavaria, who accompanied him into Italy to further their own selfish designs. The sale of a large portion of his possessions to these men enabled him to raise troops. In the autumn of 1267 he crossed the Alps with 10,000 men, and at Verona was warmly received by the Scala family, the chief of the Ghibelline party. His relatives here, persuading him to part with his remaining possessions at a low price, deserted him with their followers, leaving but 3,000 men. The Ghibellines, however, remained true to him. Verona raised a large army, Pisa a fleet, and Rome, whose pontiff was forced to flee to Viterbo, opened its gates to him. Conradin entered lower Italy, and at Tagliacozzo met the French army under Charles of Anjou, on whom the crown of Naples had been bestowed by the see of Rome. He beat Charles back, and his men, supposing the victory won, dispersed in search of plunder, when they were attacked by the French and utterly routed, Aug. 23, 1268. Conradin escaped, but was betrayed into the hands of Charles, who caused him to be beheaded in the market place of Naples, he being only 16 years of age.

CONRING, Hermann, a German philosopher and author, born at Norden, East Friesland, Nov. 9, 1606, died at Helmstedt, Dec. 12, 1681. He was the son of a clergyman, studied at Leyden, and was professor of philosophy, medicine, jurisprudence, and political science at Helmstedt, privy councillor to the duke of Brunswick, adviser of the emperor of Germany, and author of more than 100 works on Ger-

man history and jurisprudence, and on scientific and theological subjects. Queen Christina of Sweden in vain sought to attach him permanently to her service. The duke of Brunswick and the kings of Sweden and Denmark conferred titles on him, and Louis XIV. granted him a pension. He encouraged the study of chemistry and pharmacy, and was one of the first to teach Harvey's doctrine of the circulation of the blood. A complete edition of his writings, with a biography, was published by Göbel (6 vols., Brunswick, 1730).—His daughter Elisa Sophie, baroness von Reichenbach, was distinguished as a poet; she died April 11, 1718.

CONSALVI, Ercole, a Roman cardinal, born in Rome, June 8, 1757, died there, Jan. 24, 1824. His father was the marchese Giuseppe Consalvi, and his mother Maria Carandini, sister of the cardinal of that name. Educated in the college of Frascati, he won the regard of Cardinal York, who remained through life his friend and protector. He entered very young the ranks of the Roman prelacy, and was soon appointed auditor of the rota, the highest civil court in Rome, at the solicitation, it is thought, of the exiled aunts of Louis XVI. He became minister of war to Pius VI., after whose death he was chosen secretary of the conclave which elected Pius VII. This election was in a great measure due to Consalvi's tact, and his reputation for ability caused the new pope to appoint him his pro-secretary of state, then cardinal, and finally titular secretary of state. In that capacity he proceeded to Paris in 1801, to negotiate a concordat for the restoration of religion. While the pope was in France on the occasion of the coronation of Napoleon, Consalvi remained at the head of the government in Rome. In 1806, when Napoleon quarrelled with the pope, he insisted on Consalvi's removal from office. The secretary besought Pius VII. not to hesitate in accepting his resignation as a peace offering, and the pope yielded, appointing Casoni his successor. In 1810 he was compelled by Napoleon to go to Paris, and for refusing to be present at the marriage of Napoleon with Maria Louisa was banished to Rheims. In 1813 he was permitted to join the pope in Fontainebleau, and advised him to recall the concordat which he had been forced to sign. On the first restoration Pius VII. sent him to Paris to compliment Louis XVIII.; and after the final downfall of Napoleon he continued to be the representative of the holy see in the congress of Vienna. He obtained the consent of the congress that the Papal States should be restored to their integrity, and successfully resisted the partition of France. He continued at the head of the Roman government until the death of Pius VII. in August, 1823. During his administration he did much to improve the Papal States; he advised and framed the *motu proprio* of 1816, suppressing all feudal rights, monopolies, and oppressive taxes; abolished torture, and the punishment of the *corda* or estrapade; and to him also is due the abolishment of the death penalty for heresy. A new civil code, a commercial code, and a penal code were drawn up in harmony with the spirit of the age; he improved the registry of mortgages, introduced a better system of police, established workhouses in the principal towns, extirpated the banditti from the Campagna, planned the embellishment and sanitary improvement of Rome, and encouraged the liberal arts in the persons of Canova and Thorwaldsen. He left a large sum for a monument to Pius VII. Consalvi's memoirs have been published by Crétineau-Joly (2 vols., Paris, 1864).

CONSCIENCE, Hendrik, a Flemish novelist, born in Antwerp, Dec. 3, 1812. His father, a French marine speculator at Antwerp, allowed him to educate himself by eager but irregular reading. In 1829 he became a private teacher, and upon the Belgian revolution of 1830 he volunteered in the army and served six years, reaching the grade of sergeant major. During his service he wrote a number of spirited French songs, and became the popular poet of the army. Being discharged in 1836, he quarrelled with his family, and maintained himself by turns as a working gardener, an employee in the archives of Antwerp, and clerk of the academy of art. At this time a national party was trying to establish a Flemish literature in opposition to the French spirit and the philosophical ideas of the 18th century. Conscience joined this movement, and in 1837 brought out his *In het Wonderjaer* 1566 ("In the Year of Miracles 1566"), containing a series of brilliant dramatic pictures of the Spanish rule in Flanders. This was received with great popular favor, but his success enraged his father, who renounced him entirely. Through the painter Wappers, however, he obtained a small pension from Leopold I., and was able to continue his literary career. His *Leeuw van Vlaenderen* ("Lion of Flanders") appeared in 1838, and gave him a national reputation. In 1845 he was appointed assistant professor in the university of Ghent, and subsequently became instructor of the royal children in the Flemish language and literature. In 1847 he was made professor, and in 1857 commissary of the administrative department of Courtrai. In 1870 he gained the prize of literature given every fifth year, by his *Bavo en Lieveken*, which is considered by some one of his best romances. Conscience has held consistently his purpose of restoring the Flemish idiom, and has discouraged the use of French by his countrymen, although able to use it himself with ease and power. He stands in the front rank of Flemish writers. His historical romances fail in ideal characterization, but are fresh and interesting. He is most successful in his quiet pictures of home life. His works have all been translated into German, and many of them into English, Danish, Italian, and French. Besides the works mentioned above, he has pub-

lished *Phantasia* (1837), a collection of Flemish poems and legends; *Avonstunde* ("Evening Hours, 1839"), and several other graceful sketches of Flemish manners; *Geschiedenis van Belgien*, an illustrated history gathered from old chronicles (1845); and a number of novels, partly historical, among which may be mentioned *Hugo van Craenhoeve* (1845), *Lambrecht Hensmans* (1846), *Jakob van Artevelde* (1849), *Baes Gansendonck* (1850), *De arme Edelman* and *De blinde Rosa* (1851), *De Boerenkryg* (1853), *Hlodwig en Clotildis* (1854), *De Plag der Dorpen* (1855), *Batavia* (1858), *Simon Turchi* and *Aurelien* (1859), *Het yzeren Graf* (1860), *Bella Stock* (1861), *Moederliefde* (1862), and *De Kerels van Vlaenderen* (1871). He published his memoirs in the *Revue Contemporaine* in 1858.

CONSIDÉRANT, Victor, a French socialist, born at Salins, near Besançon, Oct. 12, 1808. He was educated in the polytechnic school in Paris, entered the army, and rose to the rank of captain of engineers. In 1831, having adopted the social theory of Fourier, he resigned his commission in order to devote himself to its advocacy. In 1832 he was engaged in an unsuccessful attempt to realize that theory at Condé-sur-Vesgre, about 40 m. from Paris, the funds being furnished by a wealthy Englishman. He was associated with Fourier in editing the organ of their school, and on his death in 1837 was recognized as the head of the societary school, as the body of his disciples called themselves, and became the chief editor of the *Phalange*, a monthly review, and of the *Démocratie pacifique*, a daily newspaper which they established in 1845. During this period he wrote and published several books, of which the most important is the *Destinée sociale* (3 vols., 1834–'44). On the outbreak of the revolution of February, 1848, he adhered to the republican party, and was chosen to the constituent assembly from the department of Loiret. In 1849 he was elected to the legislative assembly from the city of Paris; but taking part on June 13 in the public demonstration, headed by Ledru-Rollin, in behalf of the Roman republic, he was compelled to withdraw to Belgium, where he published *La dernière guerre et la paix définitive de l'Europe* (1850), and *La solution, ou le gouvernement direct du peuple* (1851). In 1853 he visited the United States, and selected a site in Texas for a socialistic colony. Returning to Europe in 1854, he was arrested in Brussels on a charge of conspiracy, but was soon set at liberty. A company was then organized in Paris to establish the colony in Texas, and the settlement was named Réunion, but the socialistic attempt failed. Considérant, becoming naturalized as an American, remained in Texas till 1869, when he returned to France.

CONSIDERATION, in law. See CONTRACT.

CONSISTORY, in the Roman Catholic church, the college of cardinals, assembled in session. There are three kinds of consistories: the public, secret, and semi-secret. The first is held with great pomp and ceremony, the pope presiding in full pontificals. None but cardinals are present at the deliberations of the second. Consistorial advocates are lawyers admitted to plead on matters treated of in the consistory, *e. g.*, the canonization of saints; and they enjoy many privileges and emoluments.—In English law, the court held by each bishop for the trial and disposal of all ecclesiastical causes arising in his diocese is called a consistory. In some of the reformed churches the consistory is an ecclesiastical tribunal, corresponding to a church session in the Dutch church, and in others to a presbytery.

CONSOLS, a term denoting a considerable portion of the debts of Great Britain, known as the three per cent. consolidated annuities. The government has borrowed money at different periods upon special conditions, generally the payment of an annuity of so much per cent. on the sum borrowed, and sometimes by lotteries, as in 1747, in which the prizes were funded in perpetual annuities. Owing to the confusion arising from the variety of the stocks thus created, parliament in 1757 passed an act consolidating these annuities into one fund, to be kept in one account in the bank of England, bearing 3 per cent. interest. From time to time some additions have been made to the consols, and some diminution has been effected by the operation of the sinking fund and by the application of surplus revenue; but they are redeemable only at the option of the government. They constitute a transferable stock in which there is daily speculation, and the varying price is taken as an index of the value of other public securities.

CONSPIRACY, in criminal law, a combination by two or more persons to do an unlawful act, or to do something not in itself unlawful by criminal or unlawful means. Many things not punishable when done or contemplated by a single individual, become so when several confederate for the purpose; as in case of a combination to destroy one's reputation by slander, to cheat by false warranties, &c. To render the offence complete, it is not necessary that the purpose should be accomplished, or even that any overt act be done in pursuance of the conspiracy; the offence consisting in the unlawful agreement, and not in the acts which follow it.

CONSTABLE (Fr. *connétable*, from Lat. *comes stabuli*, count of the stable, or master of the horse), a title of office borrowed from Byzantine and old French usage. The constable of France was an officer of the highest rank under the king, having the chief command of the army, the cognizance of military offences, and the authority to regulate all matters of chivalry, such as tilts, tournaments, &c. The office was suppressed by Louis XIII., but revived by Napoleon, and again suppressed at the restoration. In England the office of lord high constable is as old as the conquest, and was hereditary, with powers and duties corresponding to those

in France. It was abolished by Henry VIII., and has not since been revived except for special occasions, as on trials of peers, coronations, &c. An office with a similar title has existed in Scotland to the present day, but it is now merely honorary.—From the same derivation comes the designation of an inferior common law executive officer in England and America. Constables in England are of two kinds, the constable of the hundred, usually called the high constable, and the constable of the vill or tithing, called the petty constable or tithingman. Special constables are also sworn in by the justices on special occasions when a breach of the peace is feared or exists. Constables serve the process of justices of the peace, and they also act generally as conservators of the peace, and may arrest without warrant any person committing a breach of the peace in their presence; and on reasonable suspicion that a felony has been committed, they may arrest and detain for examination the supposed offender; but they cannot arrest without warrant for a mere misdemeanor not committed in their presence.

CONSTABLE, Archibald, a Scottish publisher, born in Fifeshire, Feb. 24, 1774, died July 21, 1827. After serving an apprenticeship to a bookseller, he opened a small shop in Edinburgh in 1795 for the sale of old books and works on Scottish history and literature. In 1801 he undertook the publication of the "Scots Magazine" and "Farmer's Magazine." Upon the establishment of the "Edinburgh Review" in 1802 he became its publisher. In 1803 he commenced the "Edinburgh Medical and Surgical Journal," and in 1805 published Sir Walter Scott's "Lay of the Last Minstrel." With the exception of the first series of the "Tales of my Landlord," he published all of Scott's works down to the year 1826, as well as the works of Dugald Stewart and other eminent Scotchmen. He also became proprietor of the "Encyclopædia Britannica," to which he published a supplement. In 1825 he commenced "Constable's Miscellany," but a few months afterward became bankrupt in the commercial revulsion of that year, Sir Walter Scott being liable for most of his debts.—See "Archibald Constable and his Literary Correspondents," edited by his son, Thomas Constable (3 vols., Edinburgh, 1873).

CONSTABLE, John, an English landscape painter, born at East Bergholt, Suffolk, in 1776, died in London, March 30, 1837. In 1800 he was admitted a student of the royal academy. He had a thorough contempt for the conventionalities of the art, and when asked by Sir George Beaumont what style he intended to adopt, replied, "None but God Almighty's style." His subjects were rural landscapes with figures, and he was fond of depicting all the phenomena connected with rain storms, the effects of dew on the grass or foliage, and other transient minutiæ. Among the best of his works are the "Valley Farm," in the Vernon gallery, and the "Corn Field," in the national gallery. In 1829 he was elected a royal academician.—See "Memoirs of John Constable, R. A., chiefly from his Letters," by C. R. Leslie, R. A. (enlarged ed., 1845).

CONSTANCE. I. (Ger. *Konstanz*, or *Kostnitz*; anc. *Constantia*), a city of Baden, on the S. shore of Lake Constance, or rather on the narrow channel which connects the lake with its N. W. arm, the Untersee, 73 m. E. N. E. of Basel; pop. in 1871, 10,052. It is walled and defended by towers and a ditch. The most interesting building is the minster, begun in 1052, rebuilt in the 16th century, and within a few years ornamented with a spire and tower of open work. The nave is supported by 16 pillars, each of a single block 18 ft. high, and there is a splendid altar, and many relics and works of art. In the merchants' hall, once a Carthusian monastery, is the room in which the council of Constance was held. The city abounds in memorials of John Huss and Jerome of Prague, who were executed here. The manufactures embrace cotton cloth, yarn, silk, musical instruments, clocks, and watches. Fishing, navigation, and agriculture employ numbers of the inhabitants. The trade is considerable, and steam communication is kept up with other towns on the lake. A bridge connects the city with the opposite suburb of Peterhausen. Constance was formerly a free imperial town, but was annexed to the possessions of the house of Austria in 1549, and by the latter ceded to Baden in 1805. **II. Lake**

Constance.

of (Ger. *Bodensee;* Lat. *Lacus Brigantinus*), a large lake in the S. W. of Germany, on the Swiss border, forming a centre in which Switzerland, Austria, Bavaria, Würtemberg, and Baden meet. It is about 1,300 ft. above the sea, and lies between lat. 47° 28′ and 47° 50′ N., and lon. 8° 52′ and 9° 42′ E.; is 40 m. long from N. W. to S. E., about 9 m. wide, 200 sq. m. in area, and 964 ft. in maximum depth. It is divided into the upper and lower lakes, the former being the larger, and the latter being subdivided into the lower lake, or Untersee, and Lake Zell, or Zellersee. The Rhine enters the lake at its S. E. end, and leaves it near Stein at the N. W. extremity, while upward of 50 other streams empty into it. Its waters are dark green, very clear, and seldom wholly frozen over, the only known instances being in the years 1695, 1830, and 1841. They are subject to sudden risings, which have never been satisfactorily explained. The shores are flat or gently undulating, fertile, highly cultivated, and dotted over with picturesque towns, villages, and ruined castles, but are not remarkable for natural scenery. Commerce is carried on by steamers and sailing vessels on the lake, and railways touch at several points on the shores. There are submarine telegraphic cables between Rorschach and Lindau, and between Romanshorn and Friedrichshafen, the latter being at a depth of about 900 ft.

CONSTANCE, Council of, a council of the Roman Catholic church, opened Nov. 5, 1414, closed April 22, 1418. The great western schism had commenced with the antipope Clement VII. (Robert de Genève), who fixed his residence at Avignon, and obtained the countenance of the French king. Urban VI. after his election had been for nearly a year acknowledged as sole pope by the whole of Christendom; and he was succeeded by Boniface IX., Innocent VII., and Gregory XII. Robert de Genève had as his successor Peter de Luna (Benedict XIII.), who maintained his claims and continued his schism until his death in 1424. The efforts made by politicians in church and state to remedy this division had failed up to the opening of the assembly in Constance. A council was held in Pisa in 1409, which took upon itself to depose both Gregory and Benedict, the pope and antipope; and a third contestant, Alexander V., was elected in their stead. This action is held by every canonist in the Roman Catholic church as utterly null in law. The rule is that there is no truly œcumenical council except such as are convened by the head of the church, and that the acts of no council in faith and morals have a binding force on the conscience save through the sanction of the pope. The council of Pisa was not therefore acknowledged as œcumenical, and its action only increased the existing confusion. In 1410 the antipope Alexander V. died, and his place was filled by Baltassare Cossa (John XXIII.). The great powers, headed by the emperor Sigismund, sought a remedy for the scandal in a meeting of the states general of Christendom. Gregory XII., the lawful pope, did not call it; and when it met, under the presidency of the antipope John XXIII., it only embraced a comparatively small number of cardinals, patriarchs, archbishops, and bishops, with a multitude of inferior ecclesiastics and laymen. John XXIII., called upon in the very first session to abdicate his dignity, bound himself by oath to do so, and then fled secretly from Constance, lest he should be held to his promise. In the perplexity caused by his flight, it was proposed to decree the superiority of the council above persons even of papal rank, with power to depose all who should refuse to obey the will of the assembly. At length the antipope John was persuaded to resign (March, 1415), was subsequently deposed (May 29), and placed in confinement near Constance. Pope Gregory, who had already solemnly pledged himself to abdicate the moment the other contestants had done so, did not wait for the abdication of Peter de Luna; but giving to the lord of Rimini, Carlo Malatesta, full power as legate, sent him to assure the assembly of Constance that he was ready to make a full renunciation of the papal dignity. This was announced in the 13th session, June 15. On the acceptance of his proposition, a bull was issued by the pope convening the council from that date, and giving thenceforth to its acts a canonical validity; after which, in July, Gregory abdicated. Peter de Luna refusing to resign, and shutting himself up in the fortress of Peñiscola, near Valencia, the fathers of the council, after waiting 100 days for an answer, commanded the cardinals to enter the conclave. On Nov. 11, 1417, they chose Ottone Colonna, who took the name of Martin V. Regarding himself as the successor of Gregory XII., he issued a bull confirming the convocation, and further confirmed all that had been done *concilianter* (*i. e.*, according to the canonical rules governing an œcumenical council) in matters of faith and morals, from the day of lawful convocation. In the earlier sessions of the council the doctrines of Wycliffe were examined and condemned. John Huss also appeared, maintained his own tenets, and was condemned and executed (July 6, 1415). His disciple, Jerome of Prague, recanted, but having relapsed was also put to death (May 30, 1416).

CONSTANS, Flavius Julius, emperor of Rome, youngest son of Constantine the Great and Fausta, born about A. D. 320, died in 350. At an early age he was appointed governor of western Illyricum, Italy, and Africa, and on the division of the empire at his father's death in 337 received those countries as his portion. His brother Constantine, having invaded his territory, was killed at the battle of Aquileia in 340, and Constans became emperor of the entire West. He is represented as weak, profligate, and rapacious. His misrule caused Magnentius, commander of the troops in Gaul,

to revolt and to send emissaries to put him to death. He fled toward Spain, but was overtaken and slain. He protected the Christian faith, as established by the council of Nice, against the Arians and Donatists, and closed many of the pagan temples.

CONSTANT DE REBECQUE, Henri Benjamin, a French orator and author, born at Lausanne, Oct. 25, 1767, died in Paris, Dec. 10, 1830. He was descended from a family of French Protestant exiles, and his father was a colonel in the service of Holland. He studied successively at the universities of Oxford, Erlangen, and Edinburgh, and became acquainted with many of the scholars and writers of France, Germany, and Great Britain. He married a German lady, and was for several years chamberlain of the duke of Brunswick. Having been divorced from his wife, he went to Paris in 1795, and began his political career as a moderate republican. His pamphlet, *De la force du gouvernement actuel de la France*, &c., attracted considerable attention; and other political writings, mostly published in the periodicals of the day, added to his reputation. At this time he became an intimate friend of Mme. de Staël, and aided in the formation of the *club de Salm*, in opposition to the royalist *club de Clichy*. In 1799 he was placed by Napoleon in the tribunate, but showed so much opposition to the first consul's encroachments upon constitutional liberty, that he was banished in 1801. Mme. de Staël was expelled from France about the same time, and with her he associated with Goethe, Wieland, Schiller, and other literary celebrities at Weimar, and at Necker's residence in Switzerland. At this time he made a translation of Schiller's *Wallenstein*, and wrote a novel called *Adolphe*. He afterward visited various European courts, and lived for a time at Göttingen, where he married Mme. de Hardenberg. In 1814 he published a pamphlet entitled *De l'esprit de conquête et de l'usurpation*, which attracted much attention. He returned to Paris in the wake of the invading armies, and espoused the cause of the Bourbons, publishing articles in their support in the *Journal des Débats*. The day before Napoleon's return from Elba he published a violent assault upon him, but was soon after invited to the palace, won over to what now appeared the cause of France, and appointed a councillor of state, the long persecuted Mme. de Staël, too, lending her influence to Napoleon. Constant now assisted in drawing up the famous *acte additionnel* to the constitution. After the battle of Waterloo, being on the proscribed list, he retired to England, but was allowed to return in September, 1816. The reactionary tendency of the government led him to join the force of so-called liberal writers, and he aided in founding the *Minerve*, and wrote many able articles on constitutional liberty and kindred subjects. He was elected to the chamber of deputies by the department of Sarthe in 1819, and became prominent as a speaker, at the same time continuing to write brilliant pamphlets and articles for periodicals on the questions of the day. After the death of Gen. Foy in 1825, he was the acknowledged leader of the opposition, besides being considered the highest expounder of monarchical constitutionalism. His health had failed before the revolution of 1830, and he was absent from Paris at the time of that outbreak. On his return he concurred in the proceedings which placed Louis Philippe on the throne, and was appointed president of the council of state. He also remained in the chamber of deputies, but his prestige was gone; and when he was presented as a candidate for the French academy, he failed of election. These disappointments are believed to have hastened his death. He had just completed his philosophical work, *De la religion considérée dans sa source, ses formes et ses développements* (5 vols., Paris, 1823–'31), and left uncompleted a supplement to it, *Du polythéisme romain considéré dans ses rapports avec la philosophie grecque et la religion chrétienne* (2 vols., 1833). His political works are edited by Laboulaye (2 vols., 1861; 2d ed., 1872).

CONSTANTIN, Abraham, a Swiss painter on porcelain, born in Geneva in 1785. He was originally an ornamenter of watch dials, but upon going to Paris devoted himself to painting on porcelain. His first work, a copy of Raphael's *Madonna della seggiola*, was executed for the empress Josephine. He afterward spent many years in Italy studying the works of Raphael. In 1832 he was commissioned by Louis Philippe to make copies of Raphael's chief works in the Vatican. The "Transfiguration" alone occupied him a year. He also made copies of the masterpieces of Titian, Correggio, and others, and in a few instances attempted original compositions and portraits from life. His best works are in the museum at Sèvres and in the royal collection at Turin. He made some valuable discoveries in the mechanical processes of his art, particularly with reference to the effect of burning upon colors.

CONSTANTIN (or **CONSTANCE**) **FAULCON,** also Phaulcon or Paulcon, a Greek adventurer, born at Custode, in the island of Cephalonia, in 1648, put to death in Siam in June, 1688. Engaged in commercial ventures in the East Indies, he was several times shipwrecked, and on one such occasion, when thrown on the coast of Malabar, met an ambassador of the king of Siam, who had also been shipwrecked. Constantin helped him to reach Siam, and in return received an appointment at the Siamese court. After the death of the prime minister, Constantin became the ruling spirit of that country. Threatened by the jealousy of the mandarins, he sought the assistance of France. In 1685 Louis XIV. despatched the chevalier de Chaumont as ambassador to Siam, while Siamese ambassadors were sent to France. The object of their negotiations appears to have been the subjection of Siam to French

rule, with Constantin as viceroy. He was made a French citizen, with the promise of the title of count, and a small force was sent out to aid him in his designs. It arrived in October, 1687, and Bangkok and Mergui were surrendered to its commander; but the native nobles raised an insurrection, and having captured Constantin had him put to death for treason. His son afterward acquired considerable influence in Siam. The adventures of Constantin have been written by Deslandes (*Histoire de Constance, premier ministre du roi de Siam*, Amsterdam, 1756), and by Gallois in the *Moniteur* (Paris, 1853).

CONSTANTINE. I. The eastern province of Algeria, bounded N. by the Mediterranean, E. by Tunis, W. by the province of Algiers, and S. (where the limit has not been precisely fixed) by territories occupied by native tribes; area, from 70,000 to 110,000 sq. m.; settled pop. in 1870, according to the report of the governor general, 137,156, of whom 33,288 were French, 21,692 other Europeans, 7,835 Jews, and 74,351 Mohammedans. Besides these there are many nomadic natives, estimated at upward of 1,000,000 in number. The territory is divided into three parts by the two ridges of the Atlas mountains: the part sloping N. to the Mediterranean and broken by spurs of the mountains; that lying between the two ridges, forming a series of fertile and well watered valleys; and that sloping S. toward the Sahara from the principal ridge of the Atlas. The largest streams are the Rumel and Seybouse. The olive and cereal grains are produced; tobacco is raised in considerable quantity, and some progress has been made in the cultivation of cotton. Mines of iron, lead, tin, and antimony have been opened, and marble quarries are worked at several points. Coral is gathered on the coast. The province is governed by a prefect, and includes the arrondissements of Constantine, Setif, Philippeville, Bona, and Guelma. It corresponds nearly to the ancient kingdom of Numidia. **II.** A city (anc. *Cirta*), capital of the province, 200 m. E. S. E. of Algiers; pop. in 1866, 35,417, of whom nearly 10,000 were Europeans. It stands on an eminence shut in on three sides by the Rumel, and connected by a low ridge on the fourth with the neighboring mountains. Its position is further strengthened by walls built by the Arabs from old sculptured stones of the Roman ruins, and by a citadel. A bridge, also of sculptured stone, crosses the ravine on one side. The old church, in the Byzantine style, is enclosed in the citadel. There are many Roman relics in and about the city. The streets are narrow and dirty, and the buildings inferior. The city has considerable trade with Tunis and with the Algerian ports, mainly in grain, fruits, and wool, while manufactures of woollen and leather goods are carried on. A bishopric was established here in 1867.—Ancient Cirta, being nearly destroyed in A. D. 311, was rebuilt and called Constantina by Constantine the Great. It belonged to Tunis for a long time, was taken by the Algerines in 1520, and came nominally into the possession of the French with the rest of Algeria in 1830, but held out against actual occupation till Oct. 13, 1837, when it was captured after a siege under Gens. Damrémont, who fell there, and Vallé.

Constantine, Algeria.

CONSTANTINE, the name of about thirteen emperors, of whom two ruled the whole Roman empire, the others only that of the East. There is much confusion in regard to the order of these emperors, some historians omitting several of them, and others adding to their number. The most conspicuous of them are noticed in the following articles; for the reigns of others see Byzantine Empire.

CONSTANTINE I., Caius Flavius Valerius Aurelius Claudius, surnamed the Great, emperor of Rome, born, according to the best authorities, at Naissus (now Nissa) in Upper Mœsia, in February, 272, died near Nicomedia, May 22, 337. His father, Constantius Chlorus, was in 292 appointed Cæsar or lieutenant emperor of the western portion of the empire, which at that time was divided between the two Augusti, or emperors, Maximian and Diocletian. Constantine was sent to serve under Diocletian as a hostage for his father's loyalty. In several campaigns in Egypt and Persia he rose to the rank of tri-

bune. When in 305 Diocletian and Maximian retired into private life, Constantine, who had everything to fear from the jealousy of the new eastern emperor Galerius, took refuge with his father, who had succeeded Maximian as emperor of the West. He followed him to England, where Constantius died in 306. The army immediately proclaimed Constantine emperor, but Galerius disapproved of the choice, and, recognizing Constantine as lieutenant emperor, appointed Severus emperor of the West. While Constantine protected Gaul and the Rhenish frontier against the invasions of the Germans, violent struggles arose at Rome between Severus and Maximian's son Maxentius, who had been elected emperor by the people and army. Maximian himself, having become tired of private life, once more laid claim to the imperial purple. He had Severus assassinated, but was overcome by his own son and compelled to seek refuge with his son-in-law Constantine, whose aid he endeavored to obtain by promising him the succession. Constantine, while preparing to comply with Maximian's request, became aware that he himself was secretly conspired against by his treacherous ally, whom he now in 310 compelled to commit suicide. Maxentius, in order to avenge his father's death, was about to set out for Gaul, when suddenly Constantine led his legions to Italy, and triumphantly entered Rome. There he was greeted as emperor by the senate, Maxentius having been accidentally drowned. During this campaign Constantine is said to have seen in the sky a flaming cross, bearing the inscription: Ἐν τούτῳ νίκα, "In this conquer." From that time the symbol of Christianity appeared on the shields of the soldiers and the banners of the Roman army. In the mean time Galerius, who still assumed supreme authority, had appointed Licinius emperor of the West, but Constantine made common cause with him. Galerius died in 311; his successor Maximin was defeated by Licinius, and thus in 313 the empire was once more divided between two rulers, Constantine for the West and Licinius for the East. The next year Constantine attempted to overthrow Licinius, but could only wrest from him Illyricum, Pannonia, and Greece. A peace of nine years followed, during which Constantine consolidated his power by reforms in the civil, military, and judicial administration. At last, in 323, he was ready to realize his desire to reunite the whole empire. He took the field against Licinius, defeated him in two battles at Adrianople and Chalcedon, compelled him to surrender, and, in spite of a solemn promise to spare his life, condemned him to an ignominious death. It is in vain that zealous writers have tried to relieve Constantine's reputation from the crimes committed to satisfy his ambition. His father-in-law, his brother-in-law Licinius, his own son Crispus, his nephew the son of Licinius, a boy of 11 years, and lastly his wife Fausta, were successively his victims. As a statesman and politician, Constantine favored and protected Christianity, though he was baptized only on his deathbed. He conceived that the vast structure of a centralized empire, comprising almost the whole civilized world, was not to be built upon the decaying remnants of paganism. A new and vigorous principle, which, by inculcating obedience to existing authorities, seemed admirably adapted to the wants of absolute monarchism, was to instil new life into the Roman empire. This may have been Constantine's idea. As early as 312 he granted absolute toleration to the Christians, and restored to them the property confiscated by his predecessors, and every attempt to restrain the religious liberty of Christians was severely punished. By convening and attending the general council at Nice (325), Constantine openly declared the Christian to be the official religion of the empire. The removal of the seat of government from Rome to Byzantium (330) was another great measure by which he intended to strengthen the empire. New Rome was to be the name of the new capital, but the name of Constantinople (the city of Constantine) prevailed. All vestiges of republican forms were extinguished by him;

Coin of Constantine.

while in the administration of affairs he brought order out of chaos, and constructed a powerful machinery of government by separating the civil from the military administration, but uniting both in the hands of the sovereign. He made his court outshine in splendor and magnificence even those of the oriental princes, and created a hierarchy of officials which to this day has remained the model of European monarchical courts. A standing army of 300,000 men and 29 naval squadrons supported the imperial authority. Heavy impositions upon the people were necessary to cover the enormous expenses, but the introduction of a regular financial system, and a just distribution of the taxes, made them appear less onerous than they would otherwise have been. With the exception of a brief war in 332 against the Goths, occupying the present Danubian principalities, the reign of Constantine after the reunion of the empire was a peaceful one. He was preparing for war against Persia when he suddenly fell ill, and died on the day of Pentecost, after having been baptized by the bishop of Nicomedia. He was buried in the church of the apostles at Constantinople.

CONSTANTINE II., emperor of Rome, eldest son of Constantine the Great by his second

wife Fausta, born at Arles in Gaul, Aug. 7, 312 (according to Gibbon in 316), killed near Aquileia, Italy, early in 340. He was named Cæsar and consul when still a little child, and in 335 was appointed governor of Gaul, Spain, and Britain. On the death of his father in 337 the empire was divided between his three surviving sons, each of whom received from the senate the title of Augustus; but a kind of supremacy was accorded to Constantine, the eldest, and he is therefore reckoned as a Roman emperor. In the partition Constantine received Constantinople, Gaul, Spain, Britain, and a small part of Africa; Thrace and the countries of the East were allotted to Constantius; and Constans was acknowledged as sovereign of Italy, Africa, and western Illyricum. Constantine became dissatisfied with the division, and demanded from Constans the cession of Africa. This being refused, he crossed the Julian Alps in 340, and invaded Italy. With a few attendants he was drawn into an ambuscade and killed. His body was found in the little river Alsa, and honored with an imperial funeral. Constans refused to share with Constantius any part of the dominions of Constantine, and thus became master of more than two thirds of the former Roman empire.

CONSTANTINE IV., surnamed Pogonatus (the Bearded), emperor of the East, born in 648, died in 685. He was the son of Constans II., who in 654 crowned him Augustus, and whom he succeeded in 668. In the following year he conducted a successful expedition into Sicily, but he was hard pressed both by the Saracens and the Bulgarians. To his two brothers he gave the title of Augustus, but allowed them no share in the government. Some of their adherents demanded that they should share the actual sovereignty, urging that as there were three equal persons in the Godhead, so there should be three equal sovereigns on earth. Constantine hung some of the theologians who advanced this argument, and the others agreed to acknowledge his supremacy. The brothers were pardoned; but their claims being again renewed, he caused their noses to be cut off in the presence of the bishops assembled in the sixth general synod of Constantinople. He gained the favor of the church by remitting the payment made on the election of a new pope; and offered the hair of his two sons on the shrine of St. Peter as a symbol of their adoption by the pope. He was succeeded by his son Justinian II.

CONSTANTINE V., surnamed Copronymus, emperor of the East, born at Constantinople in 719, died off Selymbria, Sept. 14, 775. He was the son of Leo III., was crowned by his father in 720, and in 733 married a Khazar princess, who took the name of Irene. He became emperor in 741. His reign in the interior was a long succession of atrocious crimes and excesses, if the accounts of his contemporaries, mainly religious adversaries, are to be believed. In his wars he was successful, defeating in turn the Saracens, Slavic invaders, and the Bulgarians. But he is best known by his opposition to the use of images in the churches, and to the increase of monasteries. In 754 he summoned a council at Constantinople, which after six months' deliberation unanimously declared that all visible symbols of the Saviour, except in the eucharist, were either blasphemous or heretical; that image worship was a corruption of Christianity and a renewal of paganism; and that all images should be destroyed. He laid claim to the exarchate of Ravenna, and courted the favor of Pepin, to whom he is said to have sent the first organ ever known in France.

CONSTANTINE VI., emperor of the East, born in 771, died about 797. He was the son of Leo IV. In 780 he was crowned emperor, his mother Irene acting as regent. The five sons of his grandfather Constantine Copronymus by his second marriage repeatedly conspired against him. For the first offence they were pardoned; for the second they were condemned to the ecclesiastical state; for the third the eldest was deprived of his eyes, and the tongues of the others were cut off by order of Irene. Constantine was affianced by his mother to Rotrudis, a daughter of Charlemagne, but was afterward forced by her to marry Maria, a Paphlagonian princess, whom he disliked. In 790, by the aid of his Armenian guards, he removed Irene from the regency, put her minister Stauracius to death, divorced Maria, and married Theodota, one of her attendants. His divorce and second marriage were denounced by the clergy, while by his rigor he alienated his Armenian guards, and a conspiracy was formed in favor of Irene. The emperor fled from Constantinople, but was captured and brought back to the imperial palace, where his eyes were put out by order of his mother in 797. According to one statement, he died on the same day; according to others, he survived some years in obscurity. He was the last of the Isaurian line, which had held the empire for 80 years. (See IRENE.)

CONSTANTINE VII., surnamed Porphyrogenitus ("born in the purple," or properly, in the imperial apartment called Porphyra), emperor of the East, born in 905, died Nov. 15, 959. He was the son of Leo VI., and in 911 succeeded him, his uncle Alexander being his acting colleague. On the death of Alexander in 912 Constantine became emperor under a council of regency. He had a great fondness for literature, which he cultivated, while his father-in-law, the usurping Romanus Lecapenus, who was proclaimed emperor Dec. 17, 919, administered the affairs of the empire. In 945 he became sole emperor, but he still devoted himself to literature, leaving the cares of state to his wife Helena. He is said to have been poisoned by his son Romanus, who succeeded him. Constantine occupies an important position in literature. His own works treat of subjects relating to his times, of which without them we should be in almost entire ignorance. They are all written

in Greek. The most important are: a life of his grandfather, Basil I.; Περὶ τῶν θεμάτων, a description of the provinces of the empire; *De Administrando Imperio*, a work without a Greek title, written to instruct his son in the political state of the empire, and containing much information in relation to the geography, ethnology, and politics of the time; Βιβλίον τακτικόν and Βιβλίον στρατηγικόν, two treatises on the art of war; and Ἔκθεσις τῆς βασιλείου τάξεως, which gives a detailed account of the ceremonies at the court of Constantinople. He wrote several smaller treatises on religious and other matters, and caused many works to be compiled by the most able scholars of the time.

CONSTANTINE XIII., Palæologus, the last emperor of the East, born in 1394, killed at the taking of Constantinople, May 29, 1453. He was the son of Manuel and brother of John Palæologus, emperors of Constantinople. He succeeded his brother as emperor in 1448, his succession being however disputed by his younger brother Demetrius, who claimed that, having been born in the purple, he was the legitimate heir. The sultan Amurath II. had made large conquests in the Byzantine empire, and now held his court in Adrianople; and by his assent the crown was given to Constantine, who was then in Greece. But Mohammed II., the son of Amurath, resolved to complete the conquest of the Byzantine empire by the capture of Constantinople. Constantine's appeals for aid to the princes of Christendom met with little response. The siege was formally opened April 6, 1453. The defence was obstinate, and for weeks it appeared that the siege would be unsuccessful. Mohammed offered favorable terms, which were refused by Constantine, who declared that he would find a throne or a grave under the walls of Constantinople. The decisive assault was fixed for the 29th of May, the sultan promising double pay to his soldiers, and that the man who first mounted the walls should be rewarded by the government of the richest province of his empire. While the action hung in even scales, an arrow or bullet pierced the armor of Giovanni Giustiniani, the commander of the Genoese auxiliaries, who had borne the bravest part in the defence. In spite of the remonstrances of Constantine, the Genoese troops fled through a breach which the Turks had effected, and were followed by the other auxiliaries. The walls were then stormed, and Constantine, who fought to the last, was killed by an unknown hand. His body, recognized by the golden eagles embroidered on the shoes, was discovered under a heap of slain; the head was cut off and brought to Mohammed, who however gave the body an honorable burial. It is said, though Gibbon doubts the truth of the story, that the head was sent around Persia and Arabia as a trophy.

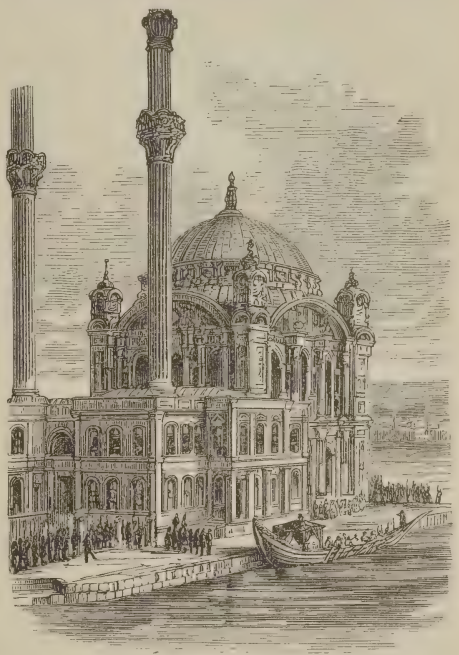
CONSTANTINE NIKOLAYEVITCH, grand duke of Russia, second son and fourth child of the emperor Nicholas, born in St. Petersburg, Sept. 21, 1827. He was made grand admiral when a mere child, and carefully educated for the navy. He visited Constantinople in 1845, and two years later made a voyage from Archangel to the Mediterranean, visiting several European cities during his absence. In September, 1848, he married Alexandra, daughter of the duke of Saxe-Altenburg. In the following year he accompanied Paskevitch in the Hungarian campaign. During the Crimean war he commanded the fleet of the Baltic in conjunction with Lütke. Being acknowledged leader of the old Russian party in opposition to the progressive views of his elder brother Alexander, his father required him to take an oath of fidelity to the heir apparent. Alexander, on his accession in 1855, placed him at the head of the ministry of the marine. He was charged with the execution of the decree which emancipated the serfs, and was made lieutenant general in Poland during the political agitations which resulted in the insurrection of 1863. In January, 1865, he became president of the council of the empire.

CONSTANTINE PAVLOVITCH, grand duke of Russia, son of the emperor Paul I., younger brother of Alexander I., and elder brother of Nicholas, born in St. Petersburg, May 8, 1779, died at Vitebsk, June 27, 1831. His grandmother, Catharine II., is said to have destined him to reign over a new empire of the East, in accordance with a popular prophecy that a Constantine should rule again at Constantinople, and attempted to educate him with that view; but he was a wilful and capricious youth, and cared for nothing but military exercises. At the age of 17 he married the princess Juliana of Saxe-Coburg, but after some years of unhappiness she left him and returned to Germany. He accompanied Suvaroff to Switzerland in 1799, and subsequently had a command at Austerlitz, and fought in several battles in the struggle with France, displaying bravery, but little skill as a commander. The duchy of Warsaw having been given to Russia by the congress of Vienna, and transformed by Alexander into a constitutional kingdom of Poland in 1815, he was made commander-in-chief of the Polish forces, with powers which made him the virtual ruler, though Zajonczek was the nominal viceroy. He gave the army a thorough discipline, but his capricious severity alienated from him the most distinguished of its officers. In 1820 he conceived a violent passion for a Polish lady, the countess Johanna Grudzinska, and through the intercession of the emperor obtained a divorce from the princess of Saxe-Coburg, with permission to marry again. In return he formally renounced for himself and his descendants the right of succession to the crown. The document containing this renunciation was kept secret until the death of Alexander in 1825, when, though actually proclaimed emperor by a revolutionary party at St. Petersburg, Constantine insisted upon maintaining his renun-

ciation, and assisted at the coronation of Nicholas, who was 17 years his junior. He continued in command at Warsaw, where his violent measures constantly fomented the anti-Russian feelings of the Poles. Four months after the breaking out of the French revolution of 1830 he was driven from Warsaw by an insurrection, and took a command in the Russian army under Diebitsch which was sent to reduce the country to subjection, but disgusted the Russians by the lack of zeal he evinced. Being recalled by the emperor, he retired to Bialystok, but was soon driven away by the Poles under Chlapowski, his brother-in-law, and not long after died of cholera. His wife, who had been made princess of Lowicz, survived him but a few months.

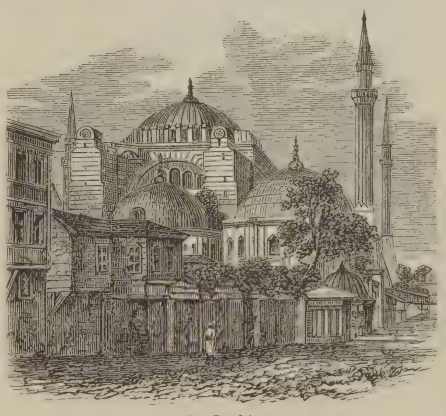
CONSTANTINOPLE (Gr. Κωνσταντινούπολις, the city of Constantine; Turkish, *Istambul* or *Stambul*), the capital of Turkey, situated at the S. W. entrance of the Bosporus, upon a triangular peninsula belonging to the European (Thracian) shore, and formed by the Golden Horn (the harbor of Constantinople), an inlet of the sea, and the sea of Marmora, in lat. 41° N., and lon. 29° E. Its population, including all its suburbs, was in 1848, according to the official tables of the board of health of that year, estimated at 778,000; the present population is by some estimated at 1,000,000, and by others, who are probably nearer the truth, at not more than 400,000 or 500,000. Of the inhabitants more than one half are Mussulmans, and the remainder are Greeks, Armenians, Jews, Persians, and other orientals, and many Levantines or native Christians of European descent. The location of Constantinople is equally favorable in a commercial and in a political point of view. Its harbor, which is capable of containing 1,200 ships, is thronged

General View of Constantinople.



by vessels of all nations, and its commanding position at the junction of the Mediterranean and Black seas would, in the opinion of many, render it, if in the possession of a strong and energetic power, the key of the political supremacy in Europe and Asia.—The picturesque aspect of the city is celebrated; but the favorable impression made by the beautiful hilly shores, beset with villas and gardens, vanishes at the first glimpse of the interior of the city. The streets, before the great fires of 1865, '66, and '70, were nearly all narrow, crooked, and exceedingly dirty, the houses dilapidated, and the atmosphere filled with offensive odors. The old city proper is about 12 m. in circumference, and is enclosed on the land side by a triple wall and moat, which, although unimportant as defensive works according to the requirements of modern military science, might in an emergency offer considerable resistance to an enemy. The wall has 27 gates. The old streets, the irregularity of which defies all attempts of the stranger to find his way, have generally no names, nor are the houses numbered; they are badly paved, not lighted at night, and in addition to their general cheerlessness they are the resort of thousands of ownerless dogs. The houses here are for the most part built of wood, and hence destructive conflagrations are of frequent occurrence. During one night in 1852, seven fires destroyed an aggregate of 3,500 houses. A still more destructive conflagration took place in September, 1865, which is said to have swept away 8,000 houses, 20 mosques, and a large number of baths, khans, and public buildings. Another

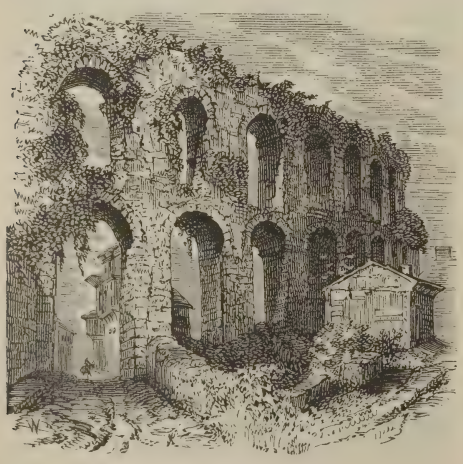
severe fire occurred in May, 1866; and still others in June, 1870, and early in 1873. The city is divided into separate districts inhabited by Turks, Greeks, Armenians, and Jews. The Turkish districts are the most extensive. The bewildering labyrinth of streets, lanes, and alleys is almost unrelieved by public squares, of which only the following are worthy of mention: At Meidan (horse square), a portion of the old hippodrome; Serai Meidan (palace square); Serasker Meidan, a portion of the old Forum Tauri; Tavuk Bazaar (poultry market); Jindi Meidan; Et Meidan, where the public executions take place; and Vefa Meidan. A feature peculiar to Constantinople is the bazaars or market halls, large fire-proof buildings lighted from above, in which hundreds of tradesmen and shopkeepers retail their wares, and some of which enclose several covered streets. Open markets for the sale of



Bazaar.

horses and cattle, fish, &c., are kept daily in several streets or squares; also a market for old clothes, not inappropriately called the Bit Bazaar, or lice market. The Avret Bazaar (women's market) was formerly set apart for the sale of female slaves. Of castles there remains only one, the castle of the seven towers (Yedi Kule), originally built as a citadel, but afterward used as a state prison for princes, and the ambassadors of nations at war with Turkey. The sultan's residence of state is the Serai Humayun (seraglio), a small walled city of itself, nearly 2 m. in circumference, and including mosques, dwelling houses, baths, gardens, governmental offices, the mint, arsenal, and treasury building. Formerly it was inhabited by at least 6,000 persons, and entirely inaccessible to strangers. The mystery which surrounded it gave rise to the most fabulous accounts of the splendor and magnificence of this imperial residence, all of which have vanished since it has been thrown open to visitors, who could not fail to see that the sultan's palace stands far

New Palace.



below the residences of other European monarchs in sumptuousness and commodiousness. The outer gate of the seraglio is called the Sublime Porte, a designation frequently applied to the Turkish government. The old seraglio (Eski Serai), erected by Mohammed II. in the centre

St. Sophia.

of the city, is about ¾ m. in circumference, and encloses the office of the secretary of war, two barracks, the military academy, &c. The number of prayer houses or mosques in Constan-

tinople is very large. There are about 500 larger ones (*jamihs*), 100 of them in the old city proper, and the number of lesser ones (*mesjids*) is given at 5,000; but this is probably an exaggeration. Unrivalled in gorgeousness is the great Agia Sofia, formerly the church of St. Sophia, originally founded by Constantine in 325, rebuilt by Justinian in 532–'8, transformed into a mosque by Mohammed II. in 1453, and renovated by the architect Fossati in 1847. The edifice is built of light bricks, but throughout lined with colored marble; its ground plan has the form of a cross, 350 ft. long and 236 wide; the diameter of the dome measures 107 ft.; the height from the ground to the cupola is 180 ft. The ceiling and the arches between the columns are inlaid with beautiful mosaic work and gilt; the gallery, 50 ft. broad, is sustained by 67 columns, some of which are of green jasper, and are said to have been taken from the celebrated temple of Diana at Ephesus; nine massive bronze portals are covered with the most artistic alto-rilievo work. Other remarkable mosques are Kutchuk (Little) Agia Sofia, built by Justinian; Kilisse Jamih (mosque of the churches), the burial place of several Byzantine emperors; Exi Marmara Jamih (mosque of the six marble columns), said to have been a temple of Jupiter; the mosque of Mohammed II., with which are connected eight *medresses* (colleges), a hospital, an eating house for the poor, &c.; the mosque of Sultan Ahmed, the only one that has six minarets; the Sulimaniye, built by Solyman the Magnificent in 1550; the Shah Sadeh Jamih (mosque of the princes), and the mosque Nuri Osmani, in the vestibule of which stands a sarcophagus of porphyry, said to have enclosed the mortal remains of Constantine the

Ruins of the Aqueduct of Valens.

Great. Constantinople is the seat of the patriarchs of the Greek and Armenian churches. The Greeks have 21 churches in the old city; the prayer houses of the other denominations are small and unimposing. The number of Mohammedan and Greek convents is considerable. No one of the numerous religious orders of the Mohammedans is without one or

Ancient Cistern.

more convents. Among the charitable institutions is a large number of *imarets* or soup houses, in which tens of thousands of persons are fed. There are 200 hospitals, in some of which Christians are provided for, over 2,000 public baths, and 40 khans (large enclosures, including warehouses and hotels). Two aqueducts 9 or 10 m. long, built by the emperors Hadrian and Constantine, furnish the city with water. The *cisterna basilica*, constructed under Justinian, the roof of which rests upon 336 marble columns, is still used as a reservoir.—The number of primary schools in Constantinople, in which only reading and the prayers are taught, is over 1,000; the former secondary schools have been abolished, and replaced by adult schools for instruction in Arabic, rhetoric, mathematics, and history. Most of the mosques have their medresses. There are also several special preparatory schools for civil service, as the college of "the sultan's mother," inaugurated in 1850, and others. Popular education is still at a very low point, despite the reforms that have been introduced by recent sultans. The military academies are as yet the only educational establishments in which a systematic course of studies, according to the modern standard of science, is pursued. Besides these, there are a medical and a veterinary college, and a naval academy. There is a number of public libraries, mostly connected with mosques, and some of them supposed to contain valuable old manuscripts.—Among the suburbs of Constantinople only five are frequently mentioned, viz.: Pera, Galata, Tophana, Kasim Pasha, and Scutari, all but the last named on or near the European shores opposite Stambul, between the Golden Horn and the Bosporus.

Pera was until the fire of 1870 the principal seat of the Christian higher classes and of the foreign ministers, and contained churches for the principal Christian denominations, several theatres and concert rooms, four hospitals (English, French, Italian, and German), three post offices (Austrian, French, and Greek), French, German, Greek, and Armenian schools, and a new French college. Gas was introduced in 1858, and telegraphic communication with London completed in the same year. Galata, built by the Genoese, is still enclosed by the old Genoese wall and moat, about 8,000 ft. in circumference. In the centre of the town stands an old round tower, originally intended as a work of defence, but now only used as a watch tower. It is 140 ft. in height, and from its top the finest view of Constantinople and its vicinity can be obtained. Galata is the principal commercial suburb of Constantinople. It is incessantly thronged by a busy crowd of merchants, clerks, carriers, seamen, &c. A merchants' exchange, the customs office, and an Austrian and an English marine hospital are among the prominent buildings. Tophana derives its importance from the large government founderies, the cannon made at which are equal to the best of European manufacture. The red and gilt Turkish clay pipes are also manufactured there on an extensive scale. Kasim Pasha contains the great arsenal and navy yard. Scutari is situated on the opposite Asiatic coast, on the site of the ancient Chrysopolis. An immense number of *kaiks* (small boats) keep up the communication between it and Constantinople. A large business in silk and cotton goods, leather, &c., is carried on there. It contains a great number of khans and warehouses, also a Turkish post office, an imperial palace, and the barracks of the imperial guards. —Constantinople had greatly improved after the conflagrations of 1865 and 1866, when the greater part of Pera was again destroyed by fire, June 5, 1870. A new quarter has since sprung up near the tower of Galata, and the arsenal, which is rapidly filling up with fine buildings, bids fair to eclipse the former advantages of Pera. In place of the old wooden bridge between Stambul and Pera, there is now a new iron floating bridge; while the irksome communication between Pera and Galata, through crooked and steep streets, which made driving impossible and even riding difficult, has been superseded by a pneumatic tunnelled railway; and the great inconvenience to commerce from the absence of good landing places is to be remedied by the establishment of quays on both sides of the harbor. Horse cars run in different parts of the city and the suburbs. The railway to Adrianople was opened in March, 1873, and other railways are in course of construction. The oriental characteristics of the city are, however, not essentially altered by these innovations. Camels, *hamals* (porters), *arabas* (clumsy Turkish carriages), dervishes, turbaned orientals of all descriptions, and veiled women still throng the streets as of old; the bazaars are still picturesque and bustling. The number of foreigners is however increasing, especially the English and Germans. Since the great fire of Pera the neighboring villages have gained in population, especially Therapia and Buyukdere.—Constantinople is the seat of important banking and commercial establishments, and is the great centre of Levantine commerce. In 1870 the number of arrivals was 24,055 sailing vessels, with a tonnage of 5,042,009, and 1,322 steamers, tonnage 1,322,926; the total arrivals in 1871 were 25,686 vessels, tonnage 5,483,818. The local industry, however, is unimportant. The principal articles of manufacture are leather ware, carpets, embroideries in gold, silver, and wool, arms, perfumes, and smoking apparatus of all kinds. In 1873 there were published in Constantinople 19 newspapers issued daily; of these 5 were in Turkish, 5 in Armenian, 4 in French, 3 in Greek, and 2 in English. Besides these there were 34 periodicals in different languages issued tri-weekly, weekly, and at longer intervals.—We have already described the origin and the history of this city down to A. D. 330, when Byzantium became Constantinople. (See Byzantium.) Afterward it was the capital of the Roman, or from 395 the Byzantine empire, and of the ephemeral Latin empire (1204–'61). In A. D. 413 an earthquake destroyed it, when it was rebuilt by Theodosius II. Its size and population under the Byzantine emperors may be judged from the fact that once, in the 8th century, 300,000 of its inhabitants fell victims to a pestilence. In the middle ages Constantinople stood a large number of sieges or assaults by Saracens, Bulgarians, Russians, Turks, and others. (See Byzantine Empire.) On May 29, 1453, it was stormed by the Turks, the last Byzantine emperor, Constantine XIII., losing his life in the defence, and since that time it has remained in their possession undisturbed.

CONSTANTINOPLE, Councils of. **I.** The second general council of the church, convened in 381 by the emperor Theodosius, at the instance of Pope St. Damasus, who approved its acts in a council held in Rome in 382. There were present 150 bishops, all belonging to the eastern churches; the chief object of the convocation being to settle the difficulties consequent upon the long domination of the Arians. The council confirmed the election of St. Gregory Nazianzen, who before the accession of Theodosius had been called to govern the church of Constantinople; and at the same time it deposed the intruder Maximus Cynicus. The acts of this council, besides the reaffirmation of the faith of Nice and the condemnation of the Macedonian and other heresies, were chiefly directed toward regulating the government and discipline of the eastern churches, and prescribing proper forms for the readmission of heretics. **II.** The fifth general council, convened in 553 by the emperor Justinian, for the

purpose of obtaining the solemn condemnation of what is known in church history as the "three chapters," viz.: the person and writings of Theodore, bishop of Mopsuestia; the writings of Theodoret, bishop of Cyrrhus, so far as they favored Nestorianism, or opposed the twelve anathemas of St. Cyril; and an epistle written by Ibas, bishop of Edessa, to one Maris, a Persian, censuring Cyril and the council of Ephesus. Justinian, who was much given to theological disputation, had been induced by the Monophysite Theodore Ascidas, bishop of Cæsarea, and by the empress Theodora, to issue in 546 a decree called "Confession of Faith," condemning these "three subjects" (*κεφάλαια*). As they had been passed on by the council of Chalcedon, Pope Vigilius looked upon this unauthorized proceeding of the emperor as a censure of the council. On his arrival in Constantinople, he excommunicated the empress and Theodore Ascidas, assembled a council of bishops, and published a sentence styled *judicatum*, in which, without pronouncing on the authenticity of the inculpated documents, he condemned their heretical meaning, "without prejudice to the council of Chalcedon." This saving clause incensed the emperor and the Monophysites, and drew upon the pope a cruel persecution which well nigh cost him his life, while the fact of his condemning the "three chapters" roused the indignation of the orthodox and produced a schism. To remedy this evil, the fifth general council was called, the pope barely yielding a reluctant assent, protesting against the partial and irregular way in which the assembly was organized, and refusing to preside over it. The meetings were called conferences. In the third the bishops gave in their adhesion to the four general councils, condemning all that was contrary thereto. In the eighth and last conference they condemned by a formal sentence the texts laid before them, as well as their authors. The pope, who had pledged himself to give his judgment separately, had prepared what is known as his *constitutum*, which was published Feb. 24, 554. While condemning the errors contained in the texts, Vigilius reminded the fathers of the council that they themselves regarded these texts as having been probably interpolated. He refused to condemn the person of Theodore of Mopsuestia, dead a century before, and reproved the animosity manifested toward Theodoret and Ibas, whose orthodoxy had been admitted by the council of Chalcedon. This doctrinal sentence and approbation of Vigilius was ratified by his successors. **III.** The sixth general council met Nov. 7, 680, under Pope Agatho, the emperor Constantine IV. assisting at some of the subsequent sessions. Its object was to condemn the Monothelite heresy, which maintains that in Christ there is but one will. The fathers, after reaffirming the doctrinal decisions of the five general councils, decreed that as in Christ both the divine and the human nature remain unconfused and entire after their union, so each nature performs its own vital operations through its proper faculties, the divine nature through the divine intellect and will, the human nature through its human intellect and will; the human will, however, being ever subject to the divine. The council closed its labors, after 18 sessions, Aug. 16, 681. **IV.** The eighth general council, 869, met in the church of St. Sophia under the presidency of the legates of Pope Adrian II., and in presence of the emperor Basil the Macedonian. Its object was to remedy the evil caused by the usurpation of Photius, who was condemned both for his intrusion and his heretical opinions. Those among his followers who subscribed to the profession of faith proposed by the council were allowed to retain their position in the church; the recusants were excommunicated and deposed. The iconoclasts were also condemned.

CONSTANTIUS. I. Surnamed Chlorus (the Pale), a Roman emperor, father of Constantine the Great, born about A. D. 250, died at York, England, in July, 306. During his short reign the emperor Carus purposed to adopt Constantius, then governor of Dalmatia, in place of his own son, the unworthy Carinus; but his sudden death in 283 prevented the execution of this project. Constantius afterward served with distinction, especially under Diocletian. In 292 the joint emperors Diocletian and Maximian made over a part of the actual exercise of government to their favorite generals, Galerius and Constantius, with the title of Cæsars, obliging each of them to divorce his wife and marry a daughter of one of the emperors. Constantius, who was appointed by Diocletian, received the government of Britain, Gaul, and Spain, his capital being the modern Treves. He defeated the Franks on the lower Rhine, the Alemanni on the upper Rhine, and the usurper Allectus in Britain. He governed with great humanity, and gave special protection to the Christians. In 305, when Diocletian and Maximian abdicated, Constantius and Galerius were proclaimed Augusti, the precedence being assigned to the former. He died while on an expedition against Scotland, 14 years after he was created Cæsar, and 15 months after receiving the title of Augustus. **II.** A Roman emperor, second son of Constantine the Great by his second wife Fausta, born at Sirmium in Pannonia, Aug. 6, 317, died at Mopsocrene in Cilicia, Nov. 3, 361. After the death of Constantine the empire was apportioned between his three sons, Constantius, then 20 years of age, receiving Thrace and the countries of the East, including Egypt. He, however, seized upon Constantinople, which had been assigned to his elder brother Constantine, and put to death two of his uncles and seven of his cousins; but it was soon agreed between the three brothers that Constantinople should be restored to Constantine. He waged a protracted war against the Persians, which prevented him from taking any

part in the struggles between his brothers in the West. Constantine was killed in 340 and Constans in 350. Constantius thereupon marched against Magnentius, who had been proclaimed in Gaul and Italy, and against Vetranio in Illyricum. They offered to compromise by acknowledging him as emperor of the East, with the preëminence in rank. He refused, having been, as he said, directed to do so by a vision of his father, the great Constantine. He offered, however, to acknowledge Vetranio as his colleague and equal, on condition that he would abandon Magnentius. A conference was appointed, but the soldiers of Vetranio deserted him, whereupon he abandoned all his claims, and was assigned an honorable abode at Prusa. Constantius then marched against Magnentius, whom he encountered and defeated in the bloody battle of Mursa (now Eszék) in Pannonia (Sept. 28, 351), and thus became sole emperor. He had in the mean time given the title of Cæsar to his cousin Gallus, and sent him to Antioch to govern the East; but in 354 he caused him to be beheaded, appointed Julian, the brother of Gallus, as Cæsar, and sent him to Gaul, where he waged a successful war against the Alemanni and Franks. Growing jealous of the renown of Julian, he ordered the recall of the legions from Gaul. A revolt ensued, and the troops proclaimed Julian emperor. Constantius moved against him, but died on the way, and Julian, afterward known as "the Apostate," whom it is said he appointed his heir on his deathbed, was peacefully acknowledged by the whole empire. Constantius is known for his zealous endeavors to establish a uniformity of faith throughout the empire. He favored the Arians, expelled Athanasius from Alexandria, persecuted the Catholics and the Novatians, and endeavored to put down pagan rites and ceremonies. **III.** A general of the Roman emperor Honorius, died in 421. He defeated Gerontius and a soldier named Constantine who had revolted and been proclaimed as emperor in Britain in 411; was made consul of Rome in 414 and 417; married Placidia, sister of Honorius, and was proclaimed joint emperor with him in 421, but died seven months after. His son became the emperor Valentinian III.

CONSTELLATIONS, the name given by astronomers to the conventional divisions of the stars. Some of these are very ancient, and would seem to have been based on actual resemblances between certain star groups and the objects with which they were originally associated. But probably the real extent of the ancient constellation figures differed very much from that at present assigned to them. Many of the 48 constellations enumerated by Ptolemy must be regarded as comparatively modern. They are as follows: 12 zodiacal constellations, Aries, Taurus, Gemini, Cancer, Leo, Virgo, Libra, Scorpio, Sagittarius, Capricornus, Aquarius, and Pisces; 20 constellations north of the zodiac, Ursa Major, Ursa Minor, Draco, Cepheus, Boötes, Corona Borealis, Hercules, Lyra, Cygnus, Cassiopeia, Perseus, Auriga, Ophiuchus, Serpens, Sagitta, Delphinus, Equuleus, Pegasus, Andromeda, Triangulum Boreale; and 16 constellations south of the zodiac, Antinous, Cetus, Orion, Eridanus, Lepus, Canis Major, Canis Minor, Argo, Hydra, Crater, Corvus, Centaurus, Lupus, Ara, Corona Australis, and Piscis Australis. To this list Tycho Brahe added one, Coma Berenices; Hevelius added 13 constellations, Bayer 12, Lacaille 14, Royer 5, and Bode, Lemonnier, Poczobut, and others, some score more. Only 36 of these new constellations are, however, admitted into the British association catalogue of stars. The leading stars in the constellations are named by Greek letters, numbers, and so on.

CONSTITUENT ASSEMBLY. See CONSTITUTIONAL CONVENTION.

CONSTITUTIONAL CONVENTION, a term applied to a convention of delegates of the people assembled to frame a constitution for the state, which may or may not be submitted to the people for ratification. When the British American colonies took up arms against the crown, the revolutionary congress which had been chosen as an advisory body assumed the general direction of military and foreign affairs, and continued by common consent to possess it after independence was declared. The extent of its authority, however, was wholly undefined, and it was without the means of enforcing its will except through state action and state officers. The necessity for some clear specification of the congressional powers soon became very urgent, and led to the adoption of the articles of confederation, which were proposed in congress and assented to by the states severally. Those articles, however, did not concede the full measure of authority essential to the vigor and efficiency of the government, the establishment of the public credit, or the preservation of faith with the public creditors; and a convention of delegates from the states was therefore called on the recommendation of congress to propose amendments. This convention met at Philadelphia in May, 1787, and organized by the choice of George Washington as its president. Being satisfied that something beyond mere amendments to the articles of confederation was required, the members proceeded to frame a new constitution, which was completed and agreed upon Sept. 17, 1787, and submitted to a convention of delegates in each state for ratification; it being provided therein that the ratification by nine states should be sufficient for its establishment between the states so ratifying. Favorable action having been obtained in the conventions of eleven states, the government was fully organized and put in operation under the constitution in March, 1789; and the two remaining states signified their assent in due form afterward. The constitution thus adopted contains within itself a provision for the calling of future conventions for amendment

or revision; but none has hitherto been called, the amendments thus far having all been made under another provision, by which congress proposes and the states ratify. The constitutions for the individual states have all been established through similar conventions. When a territory is supposed to possess the proper population for a state, it is customary for congress to pass an enabling act, under which the residents possessing the qualifications prescribed for electors in the act choose delegates to form a constitution, and the instrument agreed upon in this convention is then submitted to the people for adoption or rejection. In some cases these conventions have been called and held without the previous authority of congress; but after a constitution has been framed and adopted, and the state admitted to the Union under it, any irregularity in the incipient steps is cured. The original thirteen states have all adopted constitutions agreed upon in conventions called by legislative authority, and most of these have since been revised in similar conventions. In Connecticut and Rhode Island, however, no constitution was adopted till 1818 and 1842 respectively, the government of those states having continued to be administered under their royal charters. The convention when in session does not exercise the ordinary legislative powers. It is a disputed question whether, when not required by the act under which it is called, or by an existing constitution, to submit the result of its deliberations to the people for their action, the convention is so possessed for the time being of the sovereign power of the state that it may rightfully of its own authority and without such submission put in force a new constitution or any proposed amendments of the old. There are precedents favoring this power, particularly in the case of early conventions in the original states, and during the disorders following in what were called the border states the outbreak of the late civil war; but in many of these cases the bodies assuming this authority were, under the pressure of a supposed great public necessity, exercising ordinary powers of government, and acting rather as revolutionary conventions than as the bodies which meet to revise or form constitutions in peaceful times. Such an exercise of power is not regarded as legitimate; the convention being looked upon in the light of an advisory body, chosen for the one task of maturing a constitution, and possessing no further authority except to submit the instrument agreed upon to the people for their approval.—The corresponding body in France is called a constituent assembly (*assemblée constituante*). Two such are particularly known under the name. The first opened at Versailles May 5, 1789, as the states general, consisting of 291 deputies of the clergy, 270 of the nobles, and 584 of the *tiers état*, or middle class; but on the refusal of the nobles and clergy to sit with the representatives of the *tiers état*, the latter assumed the name of *assemblée nationale*, and began their deliberations. Louis XVI. caused their hall to be closed against them, but they assembled in a tennis court, resolved to continue united until they should have given a constitution to France, and called upon the nobility and clergy to join them. Of the nobles 47, including the duke of Orleans, yielded to the invitation, and then on command of the king the others followed, and the clergy with them. The sessions continued until Sept. 30, 1791. Among the leading members of the body were Mirabeau, Sieyès, Barnave, Cazalès, Dupont, Lafayette, and Lameth. The principal measures of the assembly were: Abolition of all feudal privileges, Aug. 4, 1789; the declaration of rights, Aug. 20; freedom of religion and of the press, Aug. 23 and 24; property of the clergy declared to belong to the nation, Nov. 2; creation of assignats, Dec. 19; division of the kingdom into departments, Jan. 15, 1790; suppression of titles of nobility, June 19; the right of pardon withdrawn from the king, June 5, 1791; the king suspended from his functions until the completion of the constitution, July 15; abolition of orders of chivalry, July 30; constitution finished, Sept. 3; accepted by the king, Sept. 13. The second constituent assembly, consisting of 900 delegates from France and its colonies, elected by universal suffrage after the proclamation of the republic, Feb. 24, 1848, met in Paris, May 4, 1848; was attacked May 15 by an insurrection led by Blanqui, but was successfully defended by a battalion of the national guard; on June 23 appointed Cavaignac dictator to put down a revolt growing out of the dissolution of the national workshops; adopted the constitution Nov. 4; ordered the election of president for Dec. 10, and after the choice of Louis Napoleon to that office held its last meeting, May 24, 1849. Each of these constituent assemblies was succeeded by a national assembly styled *assemblée législative*. The sovereign assembly which succeeded the first *législative* in 1792 is known as the convention. (See CONVENTION.) The present national assembly of France, which also claims constituent rights, was chosen by universal suffrage Feb. 8, 1871, after resistance to the power of the German army had become hopeless, and with a view primarily to a treaty of peace. It convened at Bordeaux, Feb. 12, 1871, and on the 17th appointed Thiers president of the republic. Preliminary articles of peace were ratified March 1, and the fall of the empire decreed. The assembly assumed full powers of sovereignty, which however were denied to it and resisted by the commune of Paris, and the siege and capture of that city became necessary. On March 4 the assembly adjourned its sessions to Versailles, where it convened March 20. The definitive treaty of peace with Germany, signed May 10, was ratified May 18; the gradual disbandment of the national guard was decreed Aug. 24; a formal declaration of the constituent authority of the assembly, which was

still disputed by parties in the nation and by a minority of its members, was decreed Aug. 30, and the power of Thiers as president was prolonged during its continuance. On Nov. 10 the president, who was suspected of monarchical tendencies, formally pronounced for the republic. On Jan. 19, 1872, on a disagreement with the assembly on a question of taxation, the president offered his resignation, but the assembly refused to accept it, and it was withdrawn; but on May 24, 1873, the differences between Thiers and a small majority of the assembly becoming irreconcilable, his resignation was renewed and accepted, and Marshal MacMahon was chosen president.—Constituent assemblies have also been held in some of the Spanish American republics.

CONSUL (Lat. *consulere*, to take care for), in Roman antiquity, the title of two supreme civil and military officers, by whom the republic was governed after the expulsion of the kings about 510 B. C. The office existed during 1,050 years, and assumed distinct phases in the republic and in the Latin and Byzantine empires. The consuls were at first elected annually from the patricians, had all the insignia of royalty except the crown, and were preceded by lictors bearing the symbolic fasces. The only examples of a single consul for part of a year were in 68 and 52 B. C. The plebeians, claiming a right to elect one of the consuls from their own estate, obtained as a compromise in 444 B. C. the election of one of the military tribunes who were invested with consular power. About 366 the Licinian law opened one of the consular offices to them, and in 172 both of the consuls were for the first time plebeians. In the early days of the republic the consuls were the highest judicial as well as executive and military officers, but about 365 B. C. the prætors took the judicial functions. The consuls commanded the army, proposed laws, convoked and presided over the senate and the *comitia centuriata*, and received the communications from proconsuls and from foreign states. They retained their power till Cæsar became master of the republic. The office was immediately degraded under the empire, its duration often being only from two to four months, and its principal functions being transferred to the emperor or senate. In the Byzantine empire it was a merely honorary dignity conferred by nomination of the emperor, its duties being only to assist in splendid costume at a ceremonial on Jan. 1. The number of consuls was in this late period increased, and they were of various classes. Justinian ceased to nominate consuls in A. D. 541; but the office was not legally suppressed till an act of the emperor Leo the Philosopher in 886.—The title of consul was revived for a time in the French republic after the revolution of the 18th Brumaire, 1799. The directory being overthrown, those members of the council of the ancients and the five hundred who favored the revolution appointed three consuls, Sieyès, Bonaparte, and Ducos. By the constitution of the year VIII. (Dec. 13, 1799), this form of executive was confirmed, Bonaparte being made first consul with almost absolute powers, and Cambacérès and Lebrun second and third consuls. The first consul, who was elected at first for ten years, was reëlected in May, 1802, for ten years additional, and in August of the same year for life. He promulgated laws, and appointed and dismissed the ministers and nearly all the officers, military, naval, and civil. His income was fixed at 500,000 francs, and he took up his residence at the Tuileries, where he held court in great splendor. The title was displaced by that of emperor, May 18, 1804.—The term consul designates in modern times commercial agents appointed by a government to reside at seaports or other important commercial towns of foreign countries, whose special commission is to attend to the interests of the citizens of the nation represented by such agents. They were first appointed in the 12th century, after the crusades had opened to European nations a considerable intercourse with the East. Venice, Genoa, and other Italian states obtained a recognition of semi-official agents resident at places with which there was any considerable commercial intercourse. The precedent was followed by other maritime nations, and the custom has become extended so that it is now the practice of all commercial nations to have agents wherever their citizens have established a trade. The powers and duties of consuls are in some cases regulated by treaty between the governments; in other cases there is a mere permission to send an agent, without specification of powers. A consul can do nothing that is not authorized by the government of the country to which he is sent, either by treaty or official permission; but at the present period the nature of the office is so well understood throughout the civilized world, and even by semi-civilized nations and tribes which have any commercial intercourse with other nations, that permission to appoint a consul imports that he is to be at liberty to perform the duties usually belonging to such office, unless specially provided otherwise. The duties of consuls, where they are not specified by positive stipulation between two governments, will depend upon the laws of the country represented by the consul, it being understood that such regulations are within the general scope of official powers acknowledged by the commercial world. Subject to this limitation, every nation may prescribe to its own consuls the extent and nature of their official duties. In some countries consuls are vested with judicial authority to settle disputes between citizens of the country which they represent; but this can only be by consent of the foreign government, and it has not been the practice of the English government, or of our own, to confer such authority upon its consuls, except in semi-civilized countries, as the North African and some of the

Asiatic states, where the laws are so imperfectly administered that the lives and property of foreigners could not be safely left to depend upon them. The ordinary duties of consuls relate merely to commercial affairs, such as the authentication of a ship's papers, receiving and certifying protests of masters of vessels or other persons respecting losses at sea, and giving consular certificates for various purposes. It is also required of consuls to attend to and provide for disabled seamen of the country to which they belong, and to send them home at public expense. They are also expected to take charge of stranded vessels or property belonging to their countrymen, in the absence of the master or other legal representative of the owner, and also to take care of the property of citizens of their respective countries who die within their consulates. In the consular convention between France and the United States of 1788, it was provided that our consuls should have judicial power for the settlement of disputes between the master and his crew in relation to wages or other matters strictly belonging to the interior of the ship. It has also been provided in subsequent treaties with several other European nations that consuls shall have jurisdiction over disputes between masters, officers, and crews of national vessels, while in a foreign port, on questions of wages, shipment, and discharge of seamen. The duties of consuls of the United States are defined in several acts of congress, embracing what has been above specified. Instructions in writing are generally given to them on their appointment. They must be recognized by the authorities of the country to which they are sent, and receive an *exequatur* before entering upon their duties. A consul is not, by the law of nations, entitled to the privileges of a public minister, and is subject to the laws of the country where he resides. In the Turkish dominions consuls enjoy the same immunities as ministers at Constantinople.

CONSUMPTION, in popular acceptation, and as used by physicians, a term denoting certain affections of the lungs, involving in general more or less destruction of these organs, together with progressive emaciation, and in a very large proportion of cases ending fatally. The term has been sometimes used to denote affections of other organs, but its meaning is now restricted as just stated; and although the word pulmonary is often prefixed, this word is understood wherever the term is used alone. The name derives its significance from the consuming effects as regards the lungs, and the wasting of the whole body. Another popular term is "the decline," which has a similar significance. A technical name is *phthisis*, or *phthisis pulmonalis*, the etymological sense of which is the same as consumption. Tuberculous or tubercular disease of the lungs, and pulmonary tuberculosis, are other synonymes, relating to certain characteristic morbid products within the lungs. There are still other designations which late writers have proposed, namely, tuberculous pneumonia, cheesy pneumonia, chronic lobular pneumonia, and catarrhal pneumonia. All these concur in calling the disease a pneumonia, that is, an inflammatory affection of the lungs; and the different words prefixed are intended to distinguish this disease from other forms of pneumonic inflammation. The importance of this disease is evident when its fatality and prevalence are considered. The proportion of recoveries from it is small. It prevails to a greater or less extent in almost every portion of the globe, and if those diseases which prevail as epidemics or endemics be excluded, it occasions a larger proportion of deaths than any other disease. Statistics show that of the population of Great Britain, France, Germany, and Russia, numbering less than 200,000,000, the annual deaths from this disease are about 870,000; and that of the people inhabiting the globe at least 3,000,000 die each year from this disease.—In the great majority of cases consumption is of long duration; it is therefore eminently a chronic affection. There is, however, an affection called acute consumption, acute phthisis, or acute pulmonary tuberculosis, which runs a rapid course. It is always fatal, and the duration may not extend beyond a few weeks, and sometimes death takes place within a few days from the first manifestations of disease. This affection is extremely rare. Prominent symptoms are rapid breathing, distress from a sense of the want of breath (dyspnœa), a livid coloration of the lips and face, together with more or less cough and expectoration. With these symptoms are associated high fever, as denoted by the pulse and the temperature of the body, great prostration, loss of appetite, and progressive exhaustion. After death the lungs are found filled with small round bodies which, from their resemblance in size to millet seeds, are commonly known as miliary tubercles. Other names are gray tubercles and semi-transparent granulations. The latter name is applicable to them only at an early period after their production. In a short time they become opaque and comparatively of soft consistence. Some pathologists of late propose to limit the term tubercles to these bodies, and consider that their presence is essential in order to constitute a truly tuberculous affection. Consumption in its ordinary form, that is, as a chronic affection (the sense in which the term will be used in the remainder of this article), is distinguished by other and widely different changes found after death. Generally the lungs contain cavities more or less numerous and varying in size, called by the older writers *vomicæ*. These are irregular in shape, and frequently they communicate with each other. Of course they involve an amount of destruction of the pulmonary structure proportional to their number and size. In addition to cavities, usually portions of the lungs are found to be solidified by the presence of a

morbid product which has been known as yellow and crude tubercle, or tuberculous infiltration. This is now generally regarded as an inflammatory product, and hence the propriety of calling the affection a form of pneumonia. The point of departure of the process of inflammation which occasions this product is supposed to be the membrane lining the air cells of the minute bronchial tubes. This product undergoes a cheesy degeneration, so called because it has the consistence of cheese. At length it softens so as to become changed into a thick liquid resembling purulent matter or pus. Ulceration then takes place, the liquefied product is discharged into the bronchial tubes, and it forms a certain proportion of the matter which is expectorated, leaving cavities. As a rare exception to the general rule, the discharge takes place into the pleural cavity, giving rise to a perforation of the lung, and as a consequence to the affection known as pneumohydrothorax. In most cases, after death from consumption, the several stages of the characteristic changes in the lungs are associated, because different portions of the organs are affected at successive periods of time. It is a law of the disease, to which there are occasional exceptions, that the upper part of one lung is first affected; but shortly afterward the upper part of the other is invaded; the affection then extends downward after variable intervals. Hence it is that often different sections of the lungs represent the series of changes which have taken place. In addition to the changes just noticed, in most cases miliary tubercles are found, being sometimes few in number and sometimes abundant. There is evidently some pathological connection between these tubercles and the other changes; but, as regards this connection, the views of different pathologists differ; some considering the tubercles as preceding and giving rise to the other changes, and some regarding the latter as primary, and standing in a causative relation to the former. Further morbid changes generally found on post-mortem examinations are those denoting pleurisy. As a rule, affected portions of the lungs are adherent to the walls of the chest, this being a result of circumscribed pleuritic inflammation; and in some cases the pleurisy gives rise to an effusion of liquid in greater or less quantity between the pleural surfaces, in other words within the cavity of the pleura.—The disease in the majority of cases is developed slowly and often almost imperceptibly. Usually cough is the primary pulmonary symptom. It is at first slight and dry, after a variable period becoming more marked and accompanied by expectoration. The early cough and expectoration represent a circumscribed bronchitis. As the disease progresses, the expectoration becomes abundant, consisting of mucous secretions, the liquefied tuberculous product, and purulent matter. Spitting of blood (*hæmoptysis*) is sometimes the first symptom pointing to the pulmonary affection. This symptom in some cases precedes the cough, and perhaps occurs when the health is apparently perfect. It is absent in a minority of the cases of consumption, and is apt to occur repeatedly, and in some cases a great number of times at variable intervals. The quantity of blood expectorated varies, being sometimes small and sometimes profuse. In some very rare instances the loss of blood is the immediate cause of death. In general, however, there is no danger from the hæmorrhage, and, so far as its apparent effect upon the progress of the disease is concerned, it is favorable. Statistics show that out of a considerable number of cases, the disease is non-progressive, or progresses slowly, in those in which the spitting of blood is frequent and profuse. Pain in the chest is not infrequently entirely wanting, and it is seldom a prominent symptom. The pulmonary affection in itself occasions no pain; when it occurs it is due to the pleurisy which is developed as a complication of the affection of the lungs. The pain which denotes pleuritic inflammation is short and stitch-like, and is referred by the patient to the upper part of the chest, or beneath the shoulder blade. Pain of this description occurring at intervals denotes successive attacks of circumscribed pleurisy; the pain, however, is rarely sufficient to occasion much inconvenience. The frequency of respiration is in proportion to the extent of the pulmonary affection, and the breathing becomes panting on exercise; but it is not common for patients to suffer greatly from a sense of the want of breath. With these symptoms referable to the chest are associated symptoms which it is customary to distinguish as constitutional. The pulse is more or less accelerated, and the heat of the body, as determined by the thermometer, increased. These constitutional symptoms are marked in proportion as the disease is actively advancing. Paroxysms of hectic fever occur daily in the afternoon, often commencing with a chill, and generally ending with profuse perspiration. Perspirations are of frequent occurrence without being preceded by marked febrile paroxysms, especially during sleep, whence they are known as night sweats. Chills also, or chilly sensations, are not infrequent without being followed by fever and sweating. Sooner or later the appetite fails, and there is sometimes an invincible repugnance to food. The digestion is sometimes disordered, but in many cases the food which is taken occasions no ailments referable to the stomach. As the pulmonary disease advances, there is progressive reduction of the weight of the body, ending at length in notable and sometimes extreme emaciation; and the muscular strength proportionally decreases. In females the menses diminish and at length cease. Diarrhœa is sometimes a prominent symptom, and occurring in a late period, it has been called, from the exhaustion which it occasions, colliquative diarrhœa. The ends of the fingers sometimes become enlarged or bulbous, forming the "clubbed

fingers" which are quite characteristic of this disease, although they are occasionally observed in other affections. Dropsical swelling of the feet and lower limbs is a symptom belonging to a late period of the disease. It is a remarkable fact that the mental faculties usually remain intact, with the exception that the effect of the disease upon the mind is such as often to impair the ability to appreciate the fact of the existence of a serious affection. Patients frequently, even when the disease is far advanced, entertain confident expectations of recovery. They may refuse to believe that there is any danger, and perhaps are forming plans which involve prolonged life and health when it is evident to all around them that they are on the verge of the grave. The duration of the disease in fatal cases is extremely variable. In some exceptional instances it runs a comparatively rapid course, ending in a few weeks. In such cases it has been called "galloping consumption." It rarely ends within a period of three months; it is by no means uncommon for it to extend to two or three years; and it not very infrequently lasts from 10 to 20 years. The writer has known an instance in which the disease existed for 40 years, proving fatal at the end of this period.—The diagnosis of consumption is now, with the aid of indications furnished by auscultation and percussion, made with facility and positiveness. It may be diagnosticated at an early period, before it has made much progress. Moreover, the extent to which the lungs are affected and the amount of lesion are determined with great precision. The symptoms belonging to the clinical history which are especially diagnostic, in addition to a persistent cough with more or less expectoration, are spitting of blood, stitch-like pains at the summit of the chest, irregularly recurring chills, a frequent pulse, rise of the temperature of the body, an increase of the number of respirations per minute, perspiration during sleep, febrile exacerbations or hectic paroxysms, and progressive emaciation. The signs obtained by auscultation and percussion are those which represent the morbid physical conditions incident to the disease, namely, solidification of portions of the lungs, the presence of liquid in the air tubes, roughening of the pleural surfaces with lymph, and the existence of cavities. Certain complications are significant as regards the diagnosis, such as chronic laryngitis, giving rise to huskiness and not infrequently loss of voice; tuberculous ulcerations of the intestines, causing persistent diarrhœa; perineal fistula, and chronic inflammation of the peritoneum. On the other hand, there are certain affections which appear to exert a protective influence against consumption. The disease is rarely developed in those who suffer from asthma, pulmonary emphysema, and the structural affections of the heart which produce notable disturbance of the circulation.—Our knowledge of the causes of consumption is still obscure. The popular belief is that the disease is caused by "taking cold," that is, follows a bronchitis. The study of a large number of cases fails in furnishing support for this belief. It is quite certain that a cold, whenever it appears to enter into the causation, acts only as an exciting cause, and is not sufficient in itself to produce the disease. Nor does the disease often follow acute inflammation of the lungs or pneumonia. This statement also applies to pleurisy. Statistics have shown that those who have contracted chests are not in consequence more liable to become consumptive. A hereditary influence undoubtedly enters often into the causation, persons whose parents or grandparents have been tuberculous being more likely to die of consumption than others. Moreover, facts show that sometimes, when progenitors have not been tuberculous, there is an innate constitutional tendency to consumption. As an illustration of this statement, the following may be cited: Five children of parents who were living and well died with consumption on arriving at ages of from 22 to 24; they were all the children of these parents, and none of the progenitors of the latter had been known to die with consumption. Here must have been a congenital tendency, and there is no evidence that this tendency was inherited. A predisposition relates to age. In the great majority of cases the disease is developed between the ages of 20 and 30 years; no age, however, is exempt from a liability to it. Climate has a manifest influence. Consumption prevails much more in climates which are humid and subject to frequent alternations of cold and heat, than in those which are dry and uniformly either warm or cold. Prof. Bowditch has ascertained that in the state of Massachusetts cases of consumption are especially numerous in situations in which the atmosphere is rendered humid by streams or marshes. A high altitude affords protection against the disease. A French writer, Jaccoud, states that observations for 15 consecutive years warrant him in asserting that in Alpine situations elevated 4,000 feet tuberculosis is almost unknown; and Dr. Hjaltelin, who resides in Iceland, affirms that the inhabitants of that country enjoy exemption from consumption. Statistics prove that the disease prevails especially among persons whose occupations involve a sedentary life and confinement within doors, such as clerks and printers. A conclusion to be deduced from what is known of the causation is, that causative agencies exert their influence by producing a constitutional deterioration, the essential nature of which is unknown. This condition, when it constitutes a predisposition to consumption, is called the tuberculous diathesis, and when sufficient to give rise to the disease it is called the tuberculous cachexy. An interesting and important discovery bearing on the causation of tuberculous disease was made in France in 1865, by Villemin. He demonstrated by a series of ex-

periments that tuberculous disease may be communicated by inoculation from man to certain animals, namely, rabbits and guinea pigs. These experiments have been repeated with the same result by others. It appears, however, that inoculation with morbid matter other than that from the tuberculous products is also followed by the development of tubercle. Were it true, as asserted by Villemin, that tuberculous products only are capable of producing the disease by inoculation, and that therefore these products must contain a specific morbid material of the nature of a virus, the fact would lend strong support to the opinion that consumption is to be reckoned among the contagious diseases. This opinion has been heretofore held by some, being based on instances of persons who live in close companionship, especially as husband and wife, becoming successively affected. The study of a large number of cases with reference to this point, however, affords but little evidence of the disease being communicable.—Consumption ends fatally in the great majority of cases. This well known fact leads to an underestimate of the number of cases in which recovery takes place. Cases are not extremely infrequent in which the progress of tuberculous disease ceases before the lungs have become greatly damaged. The traces of an old tuberculous affection are not very uncommon in bodies examined after death from other and various diseases. This arrest of the progress of the disease sometimes takes place spontaneously, that is, under circumstances which seem to denote an inherent tendency to recovery. Small tubercles in the lungs may undergo the calcareous degeneration; the organic matter which they contain is absorbed, leaving the mineral portion, and in this form they may be expectorated. These so-called "obsolete tubercles," or pulmonary calculi, sometimes expectorated in great numbers, are thus evidence that there has existed a tuberculous affection which, instead of progressing, has undergone retrogression. There is reason to believe that a small amount of tuberculous products may be entirely absorbed. But even when the tuberculous affection is considerable, and has advanced to the formation of cavities, recovery is by no means impossible. If fresh tuberculous products do not take place, in other words, if the tuberculous cachexy no longer continue, the cavities may cicatrize; and patients recover with a certain amount of permanent injury which, as the quantity of lung in health is greater than is required in ordinary breathing, is only felt when there is an unusual demand for the respiratory function, as in taking active exercise. Even if recovery do not take place, tuberculous cavities sometimes remain almost or quite innocuous, and under these circumstances the affection is so far mitigated that life and comfortable health may be maintained for an indefinite period.—There are no known specific remedies for the cure of consumption. This is not saying that medicines are not often useful. At the present time the remedies which are in vogue, and which in certain cases are more or less serviceable, although having no specific virtue, are the various vegetable and mineral tonics, the hypophosphites, arsenic, and cod-liver oil. The latter is perhaps a food rather than a medicine. But measures relating to diet, regimen, and climate, and other sources of hygienic influence, are vastly more important than any medicaments. The great object of treatment is the removal of the constitutional condition of which the pulmonary affection is the local expression; that is, the tuberculous cachexy. With reference to this object, all available means of strengthening and invigorating the system are to be employed. The diet should be as abundant and as nutritious as possible, embracing fatty articles of food in as large a proportion as the appetite and digestion will allow. Living out of doors as much as possible is an important part of the hygienic treatment. The writer is cognizant of several cases in which persons in advanced consumption recovered after adopting a savage life, that is, roughing it and living in the open air. Long voyages are often useful, and sometimes seem to effect a cure, instances of which have repeatedly come under the writer's observation. On the other hand, the disease sometimes pursues a favorable course under hygienic circumstances which would not be considered as conducive to this end. This statement will apply to some hospital cases. Unquestionably climatic influences are often useful, and a change from an unfavorable to a favorable climate is sometimes apparently instrumental in effecting a cure. That such a change is not curative in the majority of cases does not militate against this statement, for consumption will end fatally in a very large proportion of cases in spite of all the measures which, with our present knowledge, can be brought to bear upon the patient. If a change of climate be made, the desirable qualities of that to be selected are dryness, uniformity, elevation, and the absence of malaria. A dry, uniform, cold climate is suitable for some cases, and for others one which is dry and warm is more favorable. It is not always easy in particular cases to decide whether it is best to choose a warm or a cold climate. Perhaps the best criterion is the previous experience of the patient as to the influence upon health and vigor of the summer or the winter season. In making a change of climate, various circumstances are to be considered, such as the resources for occupation and recreation which different places offer, the feelings of the patient with respect to absence from home and separation from friends, the supply of the proper articles of diet, and the influence of associations. With reference to the latter, the moral effect of going to a place in which consumptive patients congregate is often unfavorable. As a rule, consumptive

persons should not be encouraged to deprive themselves of the comforts of home whenever the symptoms are such as to preclude a reasonable expectation of benefit. Another important rule is, that if notable benefit be derived from a change of climate, the patient should not hasten to return, and it is desirable that the change be permanent. Various details which cannot here be fully considered enter into the hygienic management. The body should be well protected against changes of temperature, but an excess of clothing is to be avoided. Consumptive persons are not more likely to "take cold" than persons in health, and in general colds do not have a pernicious influence on the progress of the tuberculous affection. Sponging the body with cold water daily, followed by brisk rubbing with a dry towel, is generally useful. The use of alcoholic stimulants, wine, spirits, or malt liquors, the choice being determined by the taste and experience of the patient, is often signally beneficial. As to the expectation of their utility in particular cases, the immediate effects are to be relied upon. In so far as they have a cordial effect, without producing upon the circulation and nervous system those effects which are understood by the term stimulation, they will be likely to be useful; and some consumptive patients are able to take the so-called alcoholic stimulants without those effects, in quantities which in health would cause intoxication. Taken under the restriction just stated, there is little or no danger of patients becoming addicted to their use. This, however, affords no warrant for their use with this object in view, except in well marked and undoubted cases of the disease. Finally, it is to be remarked that, treated after the plan which has been sketched, consumption is not fatal in so large a proportion of cases as formerly, when bleeding, cathartics, severe counter-irritation, restricted diet, and confinement within doors constituted the measures of treatment. A striking change is also manifest as regards the longer duration of the disease, and the maintenance of strength up to a short period before death in the cases which end fatally. It is an important consideration that the measures of treatment now generally pursued, when they do not effect a cure, promote a better tolerance of the disease, prolonging life, and contributing to the comfort of the patient while life continues.

CONTAGION (Lat. *contagio*, from *con*, together, and *tangere*, to touch), primarily, the propagation of disease by contact. It is scarcely distinguished in usage, even by medical writers, from infection, which designates the communication of disease by effluvia through the air. The contagious matter is the subtle, poisonous particles which diffuse themselves through the atmosphere, or attach themselves to various substances, as clothing and furniture. Concentrated in wool or fur, they retain their power of originating disease after being carried to a great distance. Among diseases propagated by immediate contagion, or direct application of the contagious matter, are syphilis, cowpox, purulent ophthalmia, and several others; among those communicated by remote contagion, or infection, are smallpox, measles, scarlet fever, mumps, and whooping cough. (See Epidemic Diseases.)

CONTARINI, a Venetian family, which counted eight doges among its members, and a large number of other persons of distinction. **I. Andrea,** doge from 1367 to 1382. The Genoese under Pietro Doria conquered Chiozza in 1379, and even threatened Venice. Andrea, then about 80 years of age, took command of the fleet, reconquered Chiozza (1380), and freed the republic from its enemies. He refused the dignity of doge when first elected, but was obliged to assume it in order to avoid being treated as a rebel. **II. Ambrogio,** a Venetian ambassador, wrote an interesting account of his journey and mission to Persia in 1473 (*Itinerario nell' anno* 1473 *ad Usun Cassan, Rè di Persia*, Venice, 1487). **III. Giovanni,** a painter, whose style was formed on that of Titian, born in 1549, died in 1605. He visited Germany, where he remained for some time, and was knighted by the emperor Rudolph II. His greatest work is a "Resurrection," in the church of San Francesco di Paola in Venice.

CONTEMPT, a disregard of the authority of a judicial tribunal or a legislative body, for which the offending party is liable to punishment by summary order, without the ordinary forms of criminal proceedings. A contempt may be either direct, as by refusal to obey an order of a court, or constructive, as when officers of a court are guilty of any corrupt conduct, abuse of process, or culpable neglect of duty. Instances of the former are when inferior magistrates or judges disobey writs issuing from superior courts, as by proceeding in a cause after it is stayed or removed by writ of prohibition, certiorari, supersedeas, and the like, or by refusal or neglect to obey some requisition made by writ of mandamus. So when parties to any suit or proceeding disobey any order made in such suit or proceeding. Thus, non-payment of costs which the court have adjudged to be paid, or the neglect to do any specific act, as to perform an award of arbitrators when the submission to the determination of such arbitrators has been made a rule of court, is held to be a contempt, for which process of attachment will be issued; but in these and the like cases the attachment is to be regarded as a civil remedy for the benefit of one party against another, rather than as criminal process for the vindication of the authority of the court; and the right to issue attachments in these cases is now restrained within narrow limits. Under the head of constructive contempts may be specified: 1. Misconduct of sheriffs and other ministerial officers by oppression, extortion, or any abuse of process placed in their hands, as

in the execution of such process they are considered the officers of the court from which it issued, and therefore directly amenable to it. 2. Fraud or malpractice of attorneys, solicitors, &c. Fair dealing between them and their clients will be enforced upon summary application. Non-payment of money collected by an attorney or solicitor will subject him to process of attachment. So when any improper advantage has been taken of a client, it will be treated as a contempt, and relief granted upon motion. The ground upon which courts interfere in such cases is the confidential relation between attorney and client, and the disrepute which would attach to the courts themselves if any want of integrity should be tolerated in their officers. In other cases courts will punish attorneys and other officers for a breach of any prescribed duty, even when there has been no private injury. Thus, a master in chancery has been adjudged guilty of a contempt in carrying on a suit in the name of another solicitor contrary to statute. (See Yates's case, 4 Johnson's Rep., 317; 6 id., 337; 9 id., 395.) So if a private person brings a suit in the name of another person without his consent or privity, it is a contempt. (2 Johnson's Rep., 291.) For any disorderly conduct in court, summary punishment may be inflicted; in other cases an attachment issues for the arrest of the offending party, and when brought in he is usually required to answer written interrogatories. If the commission of the offence is not admitted, further proof may be taken by affidavits. Upon the admission or proof of the offence, the court adjudges the party in contempt, and may prescribe punishment in its discretion, which may be either fine or imprisonment, or both. The publication in a newspaper of an article calculated to impair the respect and authority of the court has sometimes been punished as a contempt; but it is generally considered that in doing this a court occupies somewhat dangerous and doubtful ground. It is nevertheless permitted in some of the United States by statute or constitution.—The power in legislative bodies to punish contempts is analogous to that possessed by courts, and is exercised to punish disorders in their presence or which are calculated to impede their free action, to compel obedience to their proper process or that of their committees, to protect their members against unlawful arrests, &c. (6 Wheaton's Rep., 204; 14 Gray's Rep., 226; 37 New Hampshire Rep., 450.) The courts cannot review legislative decisions in cases of contempt; but where imprisonment is imposed as a punishment, it must terminate with the session of the body imposing it; and if the party is not then released, it may be done on habeas corpus.

CONTI, Princes de, a junior branch of the Condé family of France, originating from Conti or Conty, a village near Amiens. François de Bourbon, who died childless in 1614, and who was a son of the first prince of Condé, was the first to assume the title. The following are the most prominent members of the family. **I. Louise Marguerite de Lorraine,** princess de, wife of the preceding, born about 1577, died at Eu, April 30, 1631. She was a daughter of the duke Henri de Guise, *le Balafré* (the scarred), and of Catharine of Cleves, and is said to have attracted the attention of Henry IV., and to have been supplanted in his affection by Gabrielle d'Estrées. She married the prince de Conti in 1605. The only child by him dying soon after birth, she is said to have had a child by Bassompierre. She was one of the most dissolute, brilliant, influential princesses of her day, and spent the end of her life at Eu, for having given umbrage to Richelieu by her devotion to Maria de' Medici, to whom she remained faithful in adversity. She is considered the author of *Les aventures de la cour de Perse, où, sous des noms étrangers, sont racontées plusieurs histoires d'amour et de guerre arrivées de notre temps* (Paris, 1629), as well as of the *Histoire des amours du grand Alcandre* (Henry IV.), published in 1652, in which she figures under the name of Milagarde. **II. Armand de Bourbon,** regarded as the chief of the Conti family, born in Paris in 1629, died in 1666. He was a son of Henry II. de Bourbon and Charlotte de Montmorency, a younger brother of the great Condé, and godson of Richelieu. He was of feeble constitution, though of fine figure, and was destined for the church, being early provided with several rich benefices. But his love of pleasure and active life, together with the influence of his sister the duchess de Longueville, toward whom he was said to entertain more than a brotherly affection, led him to abandon theology, and to engage in the war of the Fronde against the court. After a short imprisonment he went over to the opposite side, married a niece of Mazarin, became governor of Guienne, and commanded armies in Spain (1655) and Italy (1657). Like his sister, he became devout in the latter part of his life, and wrote religious treatises. **III. Louis Armand de Bourbon,** elder son of the preceding, born in 1661, died at Fontainebleau in 1685. He was dissolute and brilliant like his father, and distinguished himself with Prince Eugene and others against the Turks. Louis XIV. banished him from court for having engaged in this warfare in spite of his prohibition, but subsequently pardoned him. His wife, Mlle. de Blois, a daughter of Louis XIV. and Mme. de la Vallière, was remarkable for her beauty and accomplishments. **IV. François Louis de Bourbon,** brother of the preceding, born in Paris in 1664, died in 1709. After the death of his brother, with whom he had fought in Hungary against the Turks, he exchanged the title of prince de la Roche-sur-Yon for that of Conti. He was banished to Chantilly, Louis XIV. bearing him a grudge for having characterized him as a stage king in the drawing room, and a chess king on the battlefield. The great Condé on his deathbed ob-

tained the pardon of his nephew, who soon distinguished himself in the field, especially at the battle of Neerwinden (1693), where he was wounded. He was elected king of Poland by a part of the nobles in 1697, but his rival Augustus of Saxony had seized the throne before he reached that kingdom, and he returned to France. In 1709 he was appointed commander-in-chief of the French army, but died at the moment of his departure for Flanders. He has been extolled by Saint-Simon and others as the hero of the Conti family. **V. Louis François de Bourbon,** grandson of the preceding, born in 1717, died in 1776. He displayed courage and skill in Piedmont, especially at the battle of Coni (1744), and in Flanders (1746). **VI. Louis François Joseph de Bourbon,** only son of the preceding, born in 1734, died in Barcelona in 1814. He bore for a long time the title of count de la Marche, and was for some time in the army. He was one of the first of the princes to leave France in 1789, after having protested against the revolution, but gave his allegiance to it on his unexpected return to Paris in 1790. He was under arrest in Marseilles, together with his cousins, the Orleans princes, from 1793 to 1795; after which he was expelled from French territory by the directory, and fled to Barcelona. He was the last prince of the house of Conti.

CONTINENTAL SYSTEM, the scheme of Napoleon I. for excluding Great Britain from commercial intercourse with the continent of Europe, and compelling her to acknowledge the maritime law established at the peace of Utrecht. By the Berlin decree of Nov. 21, 1806, the ports of France and its allied states were to be closed against all vessels coming from England or from English colonies; all commerce and correspondence prohibited; all English goods and merchandise seized; and every English subject found in the countries occupied by the French or their allies made a prisoner of war. The retaliatory measures adopted by the English government caused Napoleon to make the blockade still more stringent. The British retaliated by an order in council, Jan. 7, 1807, which prohibited neutral vessels from entering the ports of France under pain of confiscation; and a second order in council, Nov. 11, 1807, placed the harbors of France and her allies, and of all countries with which Great Britain was at war, under the same restrictions. Napoleon, by a decree issued at Milan, Dec. 17, 1807, and another, from the Tuileries, Jan. 11, 1808, declared that any vessel which had been searched by an English ship, had been sent on a voyage to England, or had paid duty to the British government, should be treated as British, and become lawful prize of war. On Aug. 3, 1810, the tariff of Trianon for colonial goods was established, followed by the decree of Fontainebleau, Oct. 18, 1810, ordering the burning of all British goods. Denmark, Russia, Austria, and Sweden were successively forced to join this hostile league against Great Britain; so that, with very few exceptions, all the ports of Europe were closed against British vessels. Though it was impossible to enforce such a system with any completeness, Napoleon refused to give it up, and his declaration of war against Russia in 1812 was chiefly occasioned by his indignation at seeing the ports of that empire reopened to English commerce. The system was finally abandoned only with the fall of the French emperor in 1814.

CONTRABAND (law Lat. *contra* and *bannum*, contrary to an edict, proclamation, or treaty), a term used to designate goods exported from or imported into a country in violation of its laws. Contraband of war, in international law, applies to goods which neutrals are prohibited from carrying during war to either of the belligerent parties. Whatever is directly of use for war, and for that only, as arms and ammunition, would of course be contraband; but articles which may be of use either in peace or war will be subject to a varying rule according to the existing circumstances. Thus, provisions may ordinarily be carried by a neutral to a belligerent without being deemed contraband; yet, in the case of a blockade of a town with the expectation of reducing it by famine, a neutral could not lawfully furnish provisions to the besieged party, as it would be giving means of assistance against one of the legitimate operations of war. Naval stores and materials for building or furnishing vessels of war are contraband by the modern law of nations; formerly they were so regarded only in a naval war, but at the present day, naval operations being more or less incident to every war, the rule has become general that the furnishing such materials to a belligerent is unlawful. It has been a question whether, if the materials are not exclusively applicable to the building or furnishing of war vessels, they would necessarily be contraband. It has been held in the English admiralty courts that they would be; but in the French council of prizes it was decided in 1807 that ordinary ship timber, adapted to the building of merchant vessels as well as vessels of war, carried to an enemy's port, was not *per se* to be deemed contraband. In the war between England and France which commenced near the close of the last century, it was attempted by both nations to enforce a stricter rule against neutral powers than had been maintained before that time by any nation of modern Europe. The national convention of France in 1793 decreed that neutral vessels laden with provisions, destined to an enemy's port, should be seized and carried to France, which was followed by an order of the English government to detain all neutral vessels bound for France having corn, meal, or flour, on board. The ground upon which England justified this detention was, that the depriving the enemy of the supplies necessary for her population was one of the means relied upon

for reducing her to accept reasonable terms of peace; and that, under this plan of operations, all provisions destined for any port of France were contraband. This claim was resisted by the government of the United States, who insisted that provisions were never contraband, except when destined to a place which was actually invested. The courts of the United States have, however, since that time admitted that provisions intended for the use of the army or navy of the enemy, or destined to his posts of military or naval equipment, should be deemed contraband; and the decisions in the English admiralty courts substantially limit the rule as to provisions being contraband to the cases above specified; so that the courts of both countries are in conformity with each other, and the claim made by the English government in 1793 seems to be abandoned, or at all events is not likely ever to be reasserted, unless in a contest as desperate as that in which she was then engaged. Confiscation is the penalty upon seizure of contraband goods, except in the case of provisions, as to which the practice has been substituted of taking them at a reasonable price instead of enforcing forfeiture. It is understood that confiscation of the goods is not a just ground of complaint on the part of the neutral power, and is not the subject of reclamation. So, on the other hand, the neutral power is not chargeable with a breach of neutrality if it allows its subjects to carry contraband goods to a belligerent. The risk of seizure and confiscation is deemed a sufficient penalty.

CONTRA COSTA, a W. county of California, bounded N. by the strait of Carquinez, Suisun bay, and the San Joaquin river, E. by the San Joaquin, W. by the bay of San Francisco, and N. W. by San Pablo bay; area, 756 sq. m.; pop. in 1870, 8,461, of whom 160 were Chinese. There are mountains in the southern part, the most considerable of which is Mt. Diablo, but the surface in other portions is generally level. The soil is fertile and productive. There are numerous salt and sulphur springs. Limestone is abundant; gypsum has been discovered; and there are quarries of red freestone and building stone of excellent quality. Valuable mines of coal have recently been opened in Mt. Diablo, and are now extensively worked. Copper and quicksilver are found. There are railroads from the coal mines to San Pablo bay. The chief productions in 1870 were 925,054 bushels of wheat, 67,025 of oats, 358,350 of barley, 18,658 tons of hay, 64,890 lbs. of cheese, 153,936 of butter, 58,800 of wool, and 10,330 gallons of wine. There were 7,033 horses, 5,366 milch cows, 9,854 other cattle, 2,556 sheep, and 7,679 swine; 4 grist mills, 5 manufactories of saddles and harness, and 1 of agricultural implements. Capital, Martinez.

CONTRACT (Lat. *contrahere*, to draw together). As its derivation denotes, a contract is a concurrence of the minds of two or more parties in reference to something to be done by one or both, and imports mutuality; that is to say, each of the contracting parties may undertake the performance of something for the benefit of the other, or one may promise to do a certain thing in consideration of what is done by the other at the time of the making of such promise, or has been previously done. Contracts may be either in express terms or implied from the acts of the parties; they may also be verbal or in writing, and at common law both forms are equally obligatory; but by statute in England and in the United States it is required that a promise shall be in writing, and signed by the party to be charged—1, when it is not to be performed within one year from the making thereof; 2, when it is to answer for the debt or default of another person; 3, when it is made in consideration of marriage, except mutual promises to marry; 4, in cases of sales of goods beyond a certain amount or value (in this country usually $50), unless there was delivery of part, or payment in part; 5, when the contract is for the sale of lands or some interest in lands, or leasing for a longer period than one year. In all these cases it is also required that the consideration shall be expressed in the writing containing the contract. An instrument under seal was at common law subject to certain legal incidents, essentially differing from those belonging to other contracts. The promise in such case is called a covenant; no consideration was required to be expressed, nor in an action brought upon such an instrument could the want of a consideration be set up as a defence, the seal being deemed of such weighty import that a consideration was presumed. The doctrine of the common law in relation to sealed instruments is peculiar, indeed may be called *sui generis*. Originally the seal was used in place of the signature, many being unable to write their names. Usually the seal had something to distinguish it, so that to some extent it could be identified; coats of arms were introduced as the devices of seals during the crusades, when it was the custom to put such devices upon the shields of knights. At that time the sealing of a deed was a sufficient execution, and the form of attestation, viz., "sealed and delivered," without mentioning the signing, has continued even to the present time, notwithstanding the statute above mentioned requiring deeds to be signed (which statute was passed in the reign of Charles II.). But after the signature became necessary, and which, as we should have supposed, would have superseded the use of the seal, the old custom of sealing still continued, and, what was more singular, had the same legal consequence as a formality. There might have been some reason for this as respected those who maintained the use of their own individual devices upon their seals; but as to the great mass of the people, the supposition of each man having his private seal was an absurd fiction, and accordingly a common stamp, with-

out any device at all, could be used for making an impression. It was required at common law that there should be an impression upon some soft substance, usually wax, which was affixed to the deed which it authenticated. The definition of a seal by Coke was: *Sigillum est cera impressa;* the wax alone without an impression would not be a seal, but it mattered not what was impressed. It became usual, especially in this country, to substitute small slips of paper for seals, which were attached by wax or wafers to the deed. While the paper was moist, an impression could be made that would be perceptible, but, as before remarked, the impression itself had nothing distinctive; hence in some of the states it has been altogether dispensed with, and a mere scroll or flourish with the pen substituted in place thereof. This would seem to be, in fact, abolishing the use of a seal as a distinct formality; yet, in all the modes of sealing, whether by wax, paper, or scroll, the legal effect has remained the same. In some states it has been provided by statute that the want of consideration may be proved in avoidance of a sealed instrument; but other incidents of sealed instruments are still in force, the most important of which is, that a longer time is allowed for bringing an action thereon, usually 20 or 10 years instead of 6, which is allowed in case of simple contracts.—The essential rules in respect to contracts are: 1, that the parties must be legally competent to make a contract; 2, there must be a sufficient consideration; 3, the contract itself, or what is agreed to be done, must be lawful; 4, in determining the legal effect of some contracts, it sometimes becomes necessary to refer to the laws of other countries, as if the contract was made or to be executed abroad, and this involves the application of rules derived from the *lex loci*, or law of the domicile, on the one hand, and the *lex fori* or *rei sitæ*, the law of the place where the subject of the contract is situated, or with reference to which the contract is supposed to have been made, on the other. 1. As to the competency of the contracting parties, it is a universal rule that there must be sufficient age, understanding, and freedom of will. The age at which contracts may be made is different in different countries. By the English and American law the age of 21 years is the time fixed for full legal ability to contract. All persons under that age are called infants, and are under disability to bind themselves except in certain specified cases. Among these is the right to make a contract of marriage, which by common law is allowed to males at the age of 14, and to females at the age of 12; by this is to be understood a contract *in præsenti*, for a promise of marriage to take effect in future is subject to the same rule as other contracts. In France the age of consent to marriage was made by the Napoleon code 18 for males and 15 for females. Another of the excepted cases is a contract by an infant for necessaries, such as clothing, food, medical aid, &c.; but he is bound only for what these necessaries are really worth, and not by any agreement he may make for a price beyond that. If, however, the infant is living with a father or guardian who provides for him, he cannot bind himself even for necessaries. So he may bind himself as an apprentice; may make a testament of chattels, if a male, at the age of 14, if a female, at the age of 12; and may be an executor at the age of 17; but these subjects are now covered by statutes. A married woman is by the common law incompetent to make contracts; but by statute in several of the states she may convey or devise her real and personal estate, being her separate property, in the same manner as if she were unmarried. Sanity of mind is also requisite to the validity of a contract. A person who is, according to legal phraseology, *non compos mentis*, is incapable of making a binding contract. Intoxication was formerly held not to constitute an exemption from liability upon a contract made while in that state; but the rule is now otherwise, and it is held that a contract is void in all cases where the person at the time of making it was without sufficient understanding to know the nature and consequences of the contract, whatever may have been the cause of such disability. Mere imbecility or weakness of understanding, when it does not amount to an entire want of reason, is not sufficient to avoid a contract, but will have great weight in inducing courts to set aside a contract if there should appear to have been unfair practice or imposition by the other party. What is called in law duress, that is to say, any improper restraint forcibly exercised over the will, is a sufficient ground for avoiding a contract made under such influence. 2. In respect to the consideration of a contract, it is a general rule that there must be something mutual. A promise made without any consideration is a *nudum pactum*, and without any legal effect. To this, however, there are two exceptions, viz.: instruments under seal, and bills of exchange or promissory notes which have passed into the hands of an innocent holder who has given value. The consideration sufficient to sustain a contract may be what is called a good consideration, as natural affection between near relations, or a valuable consideration, as money or some other reciprocal benefit. The former is sufficient as between the parties, but is not allowed to prevail against the just rights of creditors or other third persons; as if a parent should give money or other property to a child when he was unable to pay his debts, the gift could be avoided by creditors or others having an equitable lien. A valuable consideration may be either a benefit to the party promising, or some prejudice to the party to whom the promise is made. Mutual promises furnish a sufficient consideration, each to sustain the other, provided they are made at the same time. If the consideration be wholly past and executed, it will be insuffi-

cient to support a promise founded thereon, unless the prior consideration was something done at the request of the party making the promise. An existing moral obligation is not in general a sufficient consideration for a promise. If a debt has been barred by the statute of limitations, or if a debtor has been discharged from payment of his debts by an insolvent law, the original indebtedment is a sufficient consideration for a new promise; but in a case where there had been merely a prior moral and not legal obligation, the weight of authority seems to be that it is an insufficient consideration. 3. The subject of the contract, or what is agreed to be done, must be lawful. A contract is not binding by which anything is agreed to be done which the law prohibits; so certain contracts are by statute avoided as being contrary to public policy. Instances of this class of cases are contracts of loan where the borrower agrees to pay more than a certain rate of interest, wager contracts, betting upon races, and the like. Money paid or deposited upon a wager or gaming contract can be recovered back. Upon a usurious contract the lender cannot recover even the principal sum; but the borrower cannot get back what he has paid, except the excess beyond legal interest. On this subject, however, statutes have made great changes. (See Usury.) 4. As to the application of the *lex loci* and *fori* to the construction of contracts and the determination of their legal effect, and the mode and extent of expressing the same, the subject is exceedingly complicated, and will be more appropriately discussed under the proper head. We can advert here but to some few leading principles. A contract, valid at the place where it is made, is in general valid in all other places, and is to be construed according to the law of the place where made; but if the contract is made in one country and intended to be performed in another, then the general rule is that the contract is to be construed and have effect according to the law of the place where it is to be executed. As if a contract be made in England for the loan of money to be paid in the United States, interest may be taken at the rate allowed in the latter country. But if the money should be advanced and security taken in England, although the security should be a mortgage of property in the United States, then the transaction would be governed by the law of England, and only the English rate of interest could be taken. If, however, the money was to be repaid in this country, our courts would hold the contract as having reference to our laws.—As to the remedies upon contracts, they are subject to the law of the place where the action is instituted. A foreign statute of limitations can have no effect here; but a discharge under an act of bankruptcy is recognized, though in the disposition of effects of the bankrupt in this country, claims of our own citizens are preferred.

CONTRAYERVA, the root of *Dorstenia contrayerva*, a plant of the natural order *urticaceæ* and suborder *moreæ*, growing in Mexico, the Indies, and Peru. The contrayerva of the West shops is probably a product of several species of *Dorstenia*. It is a stimulant tonic and diaphoretic, but very seldom used in this country. Its reputation as an antidote for all kinds of poisons has not been proved to be well founded.

CONTRERAS, a small village of Mexico, about 10 m. S. E. of the capital, at which a battle took place between the Americans and the Mexicans, Aug. 20, 1847. (See Churubusco.)

CONUS. See Cone Shells.

CONVENT. See Monastery.

CONVENTICLE (Lat. *conventiculum*, a little assemblage), a term originally applied to a cabal among a portion of the monks of a convent, formed in secret to secure the election of an abbot according to their own wishes. It came to be used as a term of reproach, and as such was applied to the assemblies of the followers of Wycliffe in England. It was afterward applied to the secret meetings of the dissenters from the established church in England and Scotland. Prior to the revolution of 1688 several statutes were enacted for the suppression of conventicles, and they became the objects of severe persecution. The term has attained a general signification for a seditious or irregular assembly of any kind, but is little used in the United States.

CONVENTION, in diplomacy, a treaty not definite and permanent, but having some special and temporary purpose; in politics, an assembly of a special and peculiar character. According to the British constitution, no parliament can be convened by any other authority than that of the sovereign, nor can a change of dynasty form the subject of its deliberations. Accordingly, in 1660, a convention was held in London to restore Charles II. to the throne, and its acts were afterward ratified by parliament. At the revolution of 1688 the prince of Orange summoned the lords and commons to meet in convention. That body settled the succession upon William and Mary, and was afterward declared to be the two houses of parliament. There was a convention of the estates of Scotland in March, 1689, to settle the Scottish crown upon William and Mary, which was changed into a parliament on the 5th of June. The annual meetings of the commissioners of the royal burghs of Scotland are also called conventions. In America the same term was applied to those bodies which at the commencement of the revolution assumed the powers previously exercised by the colonial governments, and especially to those by which the state and national constitutions were framed.—In French history the sovereign assembly which convened after the insurrection of Aug. 10, 1792, and the imprisonment of Louis XVI., is known as the convention. This body was organized Sept. 21, 1792, and immediately abolished royalty and proclaimed the republic. It brought the king to

trial Dec. 11; condemned him to death by a majority of 26 out of 721 votes, Jan. 16, 1793; established the revolutionary tribunal, March 10; decreed the formation of the committee of public safety, April 6; allowed the arrest of 21 Girondists, June 2; completed a new constitution, Aug. 10; decreed a universal levy for the national defence, Aug. 23; condemned Marie Antoinette, Oct. 16; appointed a committee with Sieyès at its head to frame a second constitution, April 19, 1794; received and adopted this constitution, June 23; ordered the arrest of Robespierre, July 27; prohibited the affiliation of clubs, Oct. 16; suppressed the Jacobins, Nov. 12; was successfully defended by Bonaparte against the sections of Paris, Oct. 5, 1795; decreed the abolition of capital punishment, handed over the government to the directory and the council of 500, and finally adjourned, Oct. 26, after having been in session three years and 35 days, and passed 8,370 decrees.—At present the term convention is applied in the United States not only to delegated bodies specially assembled by legislative authority, but to voluntary assemblies of delegates having some change of legislation or policy in view. It is also applied to bodies assembled as the representatives of parties, to make nominations to office or settle principles of action. The great quadrennial conventions of the respective parties have since 1836 played a very important part in politics; for though they have no legal or constitutional sanction, they nominate the president and vice president, and by their platforms or declarations of principles determine the policy of the country for the next four years. Their meetings are attended by great crowds, and their proceedings, which generally take two or three days, are watched with universal interest throughout the country. (See Constitutional Convention.)

CONVERSANO, a town of S. Italy, in the province and 18 m. S. E. of the city of Bari; pop. about 10,000. It is the seat of a bishop, and contains a castle, a fine cathedral, a Benedictine nunnery, and several convents. In the middle ages it was for some time the capital of the Norman conquerors of southern Italy.

CONVEYANCE, a term formerly equivalent to voluntary alienation, and including all modes of transferring real estate by the act of the owner, whether by feoffment and livery of seisin, which was a delivery of the possession of the lands themselves in the presence of witnesses; or by an instrument in writing, signed and sealed by the person making the sale, which instrument was commonly called a deed; or by matter of record, as in the cases of fines and common recoveries, which in form were judicial proceedings, but were in fact modes of voluntary alienation; or lastly, by will, which, although like the deed it was an instrument in writing, and required the signature of the testator (but not a seal), did not take effect till after the death of the party executing. Most of the old English forms of conveyance have become obsolete. The deed of bargain and sale, which is more used than any other in England for the ordinary transfer of the fee of lands, is founded upon the statute 27 Henry VIII., called the statute of uses. (See Bargain and Sale, and Common Law.) This last mode of conveying real estate became the basis of the forms of deeds used in this country; but in most of the states a still simpler form has been adopted, corresponding more nearly with the grant or common law conveyance of incorporeal estates. In several of the states the form of deed is prescribed by statute; and various provisions have been enacted in relation to its legal effect, as that no covenant shall be implied, and what words employed shall constitute covenants, and the legal effect thereof.

CONVOCATION (Lat. *convocare*, to call together), in the church of England, the assembly of the clergy by their representatives to consult on ecclesiastical matters, under the authority of a royal writ directed to the archbishop of each province. Assemblies of inferior clergy, at the call of their respective prelates, have been common from the earliest times; but, besides such councils, there were two other kinds peculiar to England, from which the present convocation is supposed to be derived. The first was the meeting of bishops and laity to legislate for the whole kingdom; the second was the assembling of the clergy to assess taxes on their own body at a period when they claimed to be exempt from taxation by parliament. With this latter purpose, convocations had been occasionally held in Saxon times, when the subsidies granted by the church to the crown bore the name of benevolences; but in the reign of Edward I. the practice was more definitively arranged. After the surrender of the right of self-taxation in 1665 had deprived the convocation of its political character, it continued to be held nominally for ecclesiastical purposes, though its real power was lost at the reformation. An act was passed under Henry VIII. which restrained it from making any canon or ordinance opposed to the royal prerogative, or to the laws, customs, and statutes of the realm. The king's consent became necessary, not only to give validity to its acts, but to enable it to proceed to business. The provinces of Canterbury and York have each their convocation, though the latter is very rarely called. There is an upper and lower house, the former composed of the bishops, the latter of the inferior clergy, represented by all the deans and archdeacons, one proctor for every chapter, and two for the clergy of every diocese. The convocation has authority to examine and censure heretical and schismatical books and persons, but an appeal lies from its decisions to the king in council or his delegates, nor can it execute its laws and canons except under many restrictions. The clergy in convocation have the same privileges as members of parliament.

There were formerly convocations of Scotland and Ireland, but they ceased in the former country soon after the revolution, and in the latter after the union.

CONVOLVULUS (Lat. *convolvere*, to entwine), or **Bindweed,** an extensive genus of twining

Convolvulus Japonicus.

plants, annual and perennial. Most of its species have large and bright flowers, opening early in the morning, but entirely closed later in the day. The distinguishing characteristics are the funnel-shaped corolla, naked and bractless calyx, and two linear stigmas of its flowers; and its two-celled seed capsules, each cell of which contains two seeds. The more important species are the *C. Japonicus*, or Japanese convolvulus, one of the brightest and most ornamental of the kinds seen in our gardens; the *C. scammonia*, from the root of which the drug scammony is extracted; the *C. batatas*, which has an edible root, and in the reign of Queen Elizabeth was exported from the West Indies to England, and sold as an article of food, filling somewhat the place of the potato, then scarcely known; and the *C. Mauritanicus*, a beautiful dwarf trailing species.

CONWAY, a central county of Arkansas, having Arkansas river on its S. W. border; area, 1,200 sq. m.; pop. in 1870, 8,112, of whom 630 were colored. The surface is agreeably diversified by mountains and valleys, and the soil well suited for the growth of corn and cotton. There is an abundance of good pasture land; the streams furnish valuable water power, and the country along the Arkansas river is rich in stone coal. The Little Rock and Fort Smith railroad is running to the county seat. The chief productions in 1870 were 9,439 bushels of wheat, 269,945 of Indian corn, 3,955 bales of cotton, and 7,127 lbs. of tobacco. There were 2,282 horses, 580 mules and asses, 3,195 milch cows, 4,630 other cattle, 4,402 sheep, and 27,172 swine. Capital, Lewisburg.

CONWAY, a town of Carroll co., New Hampshire, on the Saco, about 55 m. N. N. E. of Concord; pop. in 1870, 1,607. The village of North Conway, a favorite resort of summer visitors and artists, is situated on the uplands overlooking the valley of the Saco. On the east is a range of hills, the largest of which is called Middle mountain, with Mt. Kearsarge (3,367 ft. high) a little to the north. West of the river is Moat mountain, with the peaks of Mt. Chocorua in the distance. Looking up the valley of the Saco, there is a very fine view of Mt. Washington. The view of Mt. Washington from the summit of Mt. Kearsarge, and down the valley of the Saco, is very beautiful. In the vicinity are Artist's falls, and Echo lake at the foot of Moat mountain.

CONWAY, Conwy, or **Aberconwy,** a market town of Carnarvonshire, N. Wales, on the left bank of the river Conway near its mouth in Beaumaris bay, 13 m. N. E. of Bangor, and 233 m. by the Northwestern and the Chester and Holyhead railways N. W. of London; pop. in

Castle and Tubular Bridge.

1871, 4,050. It has some ship-building yards, and exports timber, lead, and slates, but possesses little commercial importance. The harbor is nearly dry at low water. A suspension bridge 327 ft. long, begun in 1822 and finished by Telford in 1826, at a cost of about £40,000, connects the town with a rock in the stream, whence an embankment 2,015 ft. long and 30 ft. wide at the top, formed of mountain clay faced with stone, extends to the opposite bank. A tubular railway bridge of wrought iron was

built here by Robert Stephenson in 1848; it is 400 ft. long and 18 ft. above high-water mark, and cost £110,000. The town is surrounded by an old wall with towers and battlements. The castle, founded by Edward I. in 1283, is one of the finest structures of the kind in Great Britain; its walls, overgrown with ivy, are from 12 to 15 ft. thick, and are surmounted by eight huge towers. The remains of an old Cistercian priory, and the "great mansion," built in 1585, are also interesting objects.

CONWAY, Moncure Daniel, an American author, born in Stafford co., Va., March 17, 1832. He received his early education at the Fredericksburg academy, and afterward entered Dickinson college, Carlisle, Pa., and graduated in 1849. He began the study of law at Warrenton, Va., but abandoned this to enter the Methodist ministry. He joined the Baltimore conference in 1850, was appointed to Rockville circuit, Maryland, and in 1852 to Frederick circuit. He also wrote for the "Richmond Examiner," as a warm upholder of extreme southern opinions. Having undergone a change of political and religious opinions, he left the Methodist ministry, and entered the divinity school at Cambridge, Mass., where he graduated in 1854. He then returned to Virginia, but was obliged to leave the state on account of his political opinions, and the same year became pastor of the Unitarian church in Washington. Some anti-slavery discourses, and especially one delivered after the assault upon Senator Sumner, led to his dismissal, and in 1857 he was settled over the Unitarian church in Cincinnati. The publication of some books on slavery and its relation to the civil war led to his invitation to lecture on this subject in New England, as he had already lectured in Ohio. During the war his father's slaves escaped from Virginia and were taken by him to Yellow Springs, Ohio, and settled there. In 1863 he went to England, and there wrote and lectured on the anti-slavery aspects of the war, and contributed to "Fraser's Magazine" and the "Fortnightly Review." Toward the end of that year he became minister of South Place chapel, Finsbury, and in 1867 also of a chapel formed at St. Paul's road, Camden Town, for evening service only, which posts he still occupies. Mr. Conway has published "Tracts for To-day" (Cincinnati, 1858); "The Rejected Stone" (Boston, 1861); "The Golden Hour" (1862); "The Earthward Pilgrimage" (London, 1870); and "Republican Superstitions" (London, 1873). A work by him entitled "Sacred Anthology" was announced in London in 1873. He is a frequent contributor to the daily liberal press in England, and to various magazines and newspapers in the United States. He has lectured before several learned societies in England, and was made a fellow of the royal anthropological society of Great Britain and Ireland in 1868.

CONWAY, Thomas, an officer in the American revolution, born in Ireland, Feb. 27, 1733, died about 1800. He was educated in France, where he entered the army and attained the rank of colonel. He came to the United States in 1777, at the recommendation of Silas Deane, and was at once made a brigadier general. He was at the battles of Brandywine and Germantown, and in December, 1777, was made inspector general with the rank of major general, against the protest of Washington. All through the terrible winter which Washington passed at Valley Forge, Conway was secretly plotting against him, and endeavoring to secure the promotion of Gates to the chief command. His proceedings became so notorious that the conspiracy was known as "Conway's cabal," and he became very unpopular. Early in 1778 he sent in his resignation, which to his surprise was promptly accepted. On July 4 of that year he fought a duel with Gen. Cadwallader, and, having received what he supposed to be a mortal wound, wrote a letter to Washington in which he said, "You are in my eyes the great and good man." He recovered, however, returned to France, and in 1784 was appointed governor of Pondicherry and all the French settlements in India, with the rank of *maréchal de camp*. On the breaking out of the French revolution he was forced to fly, and his life was saved only by the interposition of the British authorities.

CONY. See RABBIT.

CONYBEARE. I. John, an English prelate, born at Pinhoe, near Exeter, in 1692, died at Bath, July 13, 1755. He studied at Exeter college, Oxford, received orders, and was curate at Fetcham in 1717. He returned to Oxford in 1718, became successively tutor in his own college, preacher to his majesty at Whitehall, rector of St. Clement's, Oxford, and in 1730 master of Exeter college. In 1732 he published his celebrated answer to Tindal's "Christianity as old as the Creation," which Dr. Warburton styles one of the "best reasoned books in the world." In that year also he was appointed dean of Christchurch; and in 1750 he succeeded Dr. Butler in the bishopric of Bristol. A collection of his sermons was published after his death in 2 vols. 8vo. **II. John Josias,** an English divine and antiquary, grandson of the preceding, born in London in 1779, died in 1824. He was educated at Christchurch college, Oxford, became usher in Westminster school, and in 1807 was elected to the Anglo-Saxon professorship in the university of Oxford. He became professor of poetry in 1812, and delivered the Bampton lectures in 1824. He made valuable contributions to the annals of philosophy and science, and wrote "Illustrations of Anglo-Saxon Poetry," a work of great value. **III. William Daniel,** an English divine and geologist, born at Bishopsgate, June 7, 1787, died at Itchenstoke, near Portsmouth, Aug. 12, 1857. He received his degree of B. A. in 1808, and of M. A. in 1811, at Christchurch college, Oxford. He was one of the earliest and most active members of the geological

society, to whose "Transactions" he was a frequent contributor. He discovered and first described in 1821 the plesiosaurus, a discovery which was applauded by Cuvier and Buckland as one of the most important additions to the sciences of geology and comparative anatomy, and which opened the path of discovery since illustrated by the labors of Owen. He also furnished several papers on the coal districts of England, which are especially valuable as proving the relations between some of the principal British rocks and the order of their superposition. He published a course of theological lectures in 1836, delivered the Bampton lectures in 1839, and in 1845 was made dean of Llandaff. He was also a fellow of the royal society, elected in 1818, and a corresponding member of the institute of France. **IV. William John,** an English clergyman and author, son of the preceding, died in 1857. He published essays in the "Edinburgh Review" on ecclesiastical and social topics, one of which, on the parties within the Anglican church, attracted general attention. These were afterward collected; and a volume of his sermons at the chapel royal, Whitehall, has been published. With the Rev. J. S. Howson he wrote the "Life and Epistles of St. Paul" (2 vols., London, 1850–'52). He also wrote a novel, "Perversion, or the Causes and Consequences of Infidelity," which was published shortly before his death, and in which the religious aspect of the times was exhibited and discussed. **V. Henry,** an English civil engineer, brother of the preceding, born at Brislington, Somersetshire, Feb. 22, 1823. On the completion of his professional education he went to India, and from 1849 to 1852 had charge of the civil engineering department of the city and island of Bombay. In 1854 his report on the best means of supplying water to the city and island was approved by the supreme government of India, and he was appointed to construct the works, which were on an unusually large scale. He returned to England in 1855, and in 1856 designed docks for the port of Bombay. The same year he was appointed lecturer on civil engineering in the royal engineers' establishment for field instruction at Chatham. He has since been engaged in the construction of public works of importance in England.

COOK. I. A N. county of Texas, separated from the Indian territory by Red river, and drained by Elm fork of Trinity river and its affluents; area, 900 sq. m.; pop. in 1870, 5,315, of whom 471 were colored. The E. third of the county is wooded; the rest is prairie, except along the rivers. The bottom lands of Red river are very rich. The route of the proposed Memphis, El Paso, and Pacific railroad lies through it. The chief productions in 1870 were 16,233 bushels of wheat, 211,939 of Indian corn, 51,743 of oats, 22,664 of sweet potatoes, 76,809 lbs. of butter, and 308 bales of cotton. There were 3,479 horses, 3,015 milch cows, 27,503 other cattle, 3,086 sheep, and 16,226 swine. Capital, Gainesville. **II.** A N. E. county of Illinois, touching Indiana and Lake Michigan; area, 1,027 sq. m.; pop. in 1870, 349,966. The surface is level or undulating, much of it being occupied by prairies. The soil is remarkably rich and deep. The flat land was formerly thought unfit for cultivation, but is now generally esteemed the best since careful tillage has developed its richness. It is traversed by the Illinois and Michigan canal, and by various railroads centring in Chicago. It was organized in 1831, and named after Daniel P. Cook, a member of congress from Illinois, by whose exertions a grant of 300,000 acres of land was obtained from the United States to aid in the construction of the Illinois and Michigan canal. The chief productions in 1870 were 149,200 bushels of wheat, 570,427 of Indian corn, 1,584,225 of oats, 59,973 of barley, 444,554 of potatoes, 129,210 tons of hay, 1,088,963 lbs. of butter, 57,372 of wool, 36,505 of flax, and 2,644,960 gallons of milk sold. There were 12,770 horses, 23,063 milch cows, 14,486 other cattle, 10,622 sheep, and 15,521 swine. There are a large number of manufacturing establishments, chiefly in Chicago, the county seat.

COOK, Charles, D. D., an English clergyman, one of the founders of French Methodism, and president of the French Wesleyan conference, born in London, May 31, 1787, died Feb. 21, 1858. After a few years devoted to the work of education, he entered the Wesleyan ministry in 1817, and in 1818 was appointed by the British conference to the French mission in Caen, Normandy. Through his labors societies were organized, circuits were formed, and a native ministry recruited from year to year. He was a powerful co-worker with D'Aubigné, De Felice, Malan, Gaussen, the Monods, and others in the revival among the French Protestants. At his death there were in France 2 Methodist districts, 12 circuits, 141 chapels, 26 itinerants, 65 local preachers, 1,386 members, day and Sunday schools, a monthly periodical, and Bible, tract, and missionary societies.

COOK, Dutton. See supplement.

COOK, Eliza, an English authoress, born in Southwark, London, in 1817. Her father was a tradesman in narrow circumstances; and her mother dying when she was 15 years of age, her home was neither pleasant nor happy. She had early evinced a taste for literature, and now sought in intellectual pursuits relief from the hardships of her situation. In 1837 she became a contributor to the London "Weekly Despatch," and wrote for other periodicals. In 1840 a collection of her poems, under the title of "Melaia and other Poems," was published in London. In 1849 she became the editor of "Eliza Cook's Journal," a weekly publication, designed, in her own words, "to aid the gigantic struggle for intellectual elevation now going on." For several years it contained many vigorous prose articles and poems from her pen, but was discontinued in 1854 on account of her

illness. Several editions of her poems have been published, and in 1864 a new volume appeared under the title of "New Echoes and other Poems." The same year she obtained a literary pension of £100.

COOK, James, an English navigator, born at Marton, Yorkshire, Oct. 27, 1728, killed at the Sandwich islands, Feb. 14, 1779. His father was a farm laborer; and in his 13th year the future navigator was apprenticed to a haberdasher in Staiths, a little fishing town near Whitby. His father dying, he persuaded his master to give up his indentures, and engaged himself as cabin boy in one of the coasting vessels of Whitby. Having spent several years in this service and become master of a vessel, in 1755 he shipped in the royal navy, and was speedily promoted to the quarter deck for his efficiency. Having been master successively of the sloop Grampus and the Garland, in 1759 he had his master's rank confirmed by the admiralty and was appointed to the Mercury, a frigate belonging to the squadron sent out to coöperate with Gen. Wolfe at Quebec. He piloted the boats of the squadron to the attack of Montmorency; conducted the disembarkation of the troops for the assault on the heights of Abraham; made careful soundings, and afterward published a chart of the channel of the St. Lawrence from Quebec to the sea. Being promoted to the flag ship Northumberland, he made use of his leisure to study mathematics and astronomy. In 1762 he was present at the recapture of Newfoundland. Returning to England, he married, and in 1763 came out to survey the coast of Newfoundland, and in the following year was appointed marine surveyor of that coast and of Labrador. Meantime he had published a number of charts, and while near Cape Ray was able to observe an eclipse of the sun. The record of his observations, published in the "Philosophical Transactions," showed an accuracy which gave him a high reputation as an astronomer. When the royal society obtained the consent of the king to fit out an expedition for the purpose of observing the transit of Venus over the sun's disk, which could only be done in the Pacific ocean, he was chosen to command the vessel. He received a royal commission as lieutenant, chose the Endeavor, of 370 tons, as the expedition ship, and sailed Aug. 23, 1768, from Plymouth, accompanied by Mr. Green as astronomer, and Mr. (afterward Sir Joseph) Banks as naturalist of the expedition. On April 13, 1769, the Endeavor reached Tahiti, where the necessary astronomical observations were successfully made. He next sailed in search of the Antarctic continent, then believed to exist near the south pole; rediscovered New Zealand, and first saw the narrow strait which divides it into two parts; took possession of the coast of Australia about Botany bay in the name of the king of Great Britain, and laid down 1,300 m. of the coast line; proved by actual investigation the entire separation of that island and Papua; after various escapes from shipwreck and native hostility, put into Batavia to refit, where 30 of his men died of the country sickness; and finally reached England, June 11, 1771, having in less than three years circumnavigated the globe and fulfilled the various objects of the expedition. His journal and the papers of Banks were used by Dr. Hawkesworth as material for his account of the voyage. Australia being demonstrated to be an island, the great southern continent was supposed to lie nearer the pole. To settle this point, it was determined to send out another expedition. Two ships, the Resolution, of 462 tons and 112 men, commanded by Cook, and the Adventure, of 336 tons and 81 men, commanded by Tobias Furneaux, sailed from Plymouth, July 13, 1772, with instructions to "circumnavigate the whole globe in high southern latitudes, making traverses from time to time into every part of the Pacific ocean which had not undergone previous investigation, and to use his best endeavors to resolve the much agitated question of a southern continent." After sailing over 3,660 leagues, reaching lat. 71° 10′ S., in lon. 106° 54′ W., and being out of sight of land 117 days, the Resolution (May 18, 1775) rejoined the Adventure at New Zealand. Cook was now satisfied that no continent existed at the south; but after wintering in the Society islands, he examined the waters to the eastward of his former cruise, between lat. 60° and 70°; then explored the ocean between lat. 43° and 56°, from Easter island to the New Hebrides; discovered and named the island of New Caledonia; and finally turned eastward toward Cape Horn, and returned by way of the Cape of Good Hope to England, arriving July 30, 1775, after an absence of three years and 16 days, in which time the vessels had sailed over 20,000 leagues. He was now made post captain, and appointed a captain of Greenwich hospital. He was also chosen member of the royal society, Feb. 29, 1776, and received the Copley gold medal for the best experimental paper of the year, in which he gave an account of his method of preserving the health of his men. The possibility of achieving a northwest passage to Asia had begun again to occupy the public mind, and Cook volunteered to take charge of an expedition to ascertain its practicability by making the attempt by way of Behring strait. He sailed from Plymouth July 12, 1776, with two ships, the Resolution and Discovery, the latter under command of Capt. Charles Clerke. After spending some time in exploring the islands of the South Pacific, he set out for Behring strait, and on his way, in January, 1778, discovered the group which he named the Sandwich islands. Circumnavigating these, and laying down their position on the chart, he reached the coast of America in March, sailed up a sound since known as Cook's inlet, and finding no passage through set out for Behring strait. Here he was stopped by an impassable barrier of ice. He determined the most west-

erly point of America and its distance from Asia, reached the point still known by the name he gave it, Icy cape, Aug. 18, 1778, and did not turn back till the end of the month, when he found it impossible to proceed. Returning to the Sandwich islands to prepare for another attempt northward the next year, he discovered Hawaii, the largest of the group, and Maui. He cruised about Hawaii several weeks, and found the natives peaceably disposed, but addicted to stealing. One of his boats being stolen on the night of Feb. 13, 1779, he determined to seize the person of the king and hold him until the property was restored. Going ashore for the purpose on the 14th, with a lieutenant and nine men, he aroused the suspicions of the natives, and a fight ensued in which he was killed. The body, and those of several marines who were slain, were afterward cut up and probably devoured, only the bones of the great navigator being recovered by the expedition seven days later. These were deposited in a coffin, and buried in the sea. After another unsuccessful attempt in Behring strait, the expedition returned home by way of China. Cook's widow received a pension of £200 per annum, and each of his children £25. An account of his last voyage was prepared from his journal, and a continuation of it by Lieut. King. The charts and plates illustrating it were executed at the expense of the government, and half the profits of the work were bestowed on his family.

COOK, Joseph. See supplement.

COOKE, George Frederick, an English actor, born in Westminster, April 17, 1755, died in New York, Sept. 26, 1812. His father, an Irish captain of dragoons, died soon after his birth, and his mother removed to Berwick-upon-Tweed, where he was placed at school, and afterward apprenticed to a printer. Conceiving a strong passion for the stage, he indulged it for some time in private, and first appeared as a professed actor at Brentford in 1776, as Dumont in the tragedy of "Jane Shore." He performed at the Haymarket in London in 1778, without attracting attention, and after being a member of several provincial companies first attained popularity at Manchester in 1784. In 1794 he joined the Dublin company, became the hero of the stage at Dublin, Cork, and Manchester, and in 1800 accepted an engagement at Covent Garden, London, where he appeared with decided success as Richard III. For ten years he was the rival of John Kemble, and played both in tragedy and comedy in the largest cities of Great Britain. His most popular characters were those of Richard III., Shylock, Iago, Sir Giles Overreach, Kitely, and Sir Pertinax Macsycophant. In 1810 he sailed for America, and on Nov. 21 appeared as Richard III. in the Park theatre, New York. He subsequently acted in Philadelphia, Baltimore, and other cities, attracting large audiences, whom he annoyed by his capricious conduct and astonished by his wonderful acting. His death was hastened by his intemperate habits. His memoirs were written by William Dunlap in 1812, and notes of his conversation and many incidents of his life and associates in New York are contained in Dunlap's novel of "Thirty Years Ago" (1836). He is buried in St. Paul's churchyard, New York, where a monument was erected to his memory by Edmund Kean in 1821.

COOKE, George Wingrove, an English lawyer and author, born in Bristol about 1814, died at Chelsea, June 18, 1865. He studied at the London university, in Oxford, and at the Middle Temple, and was called to the bar in 1835. He was for a time the political editor of the "Atlas" newspaper, and in 1857–'8 was a special correspondent of the "Times" in China. In 1850 and 1851 he was an unsuccessful candidate for parliament. In 1863 he was appointed tithe, copyhold, and enclosure commissioner, in which department he had previously been long employed as a lawyer. Besides several legal works, he published "Memoirs of Lord Bolingbroke" (1835), "Life of the Earl of Shaftesbury" (1836), "History of Party" (1836), "Inside Sebastopol" (1856), "China in 1857–'8" (1858), and "Conquest and Colonization of North Africa" (1860).

COOKE. I. John Rodgers, an American jurist, born in Bermuda in 1788, died in Richmond, Va., Dec. 10, 1854. During a professional career of more than 40 years, he was concerned in nearly all the great causes carried to the higher courts of Virginia. He served in the legislature in 1814, and in 1829 was a member of the convention which framed the constitution of Virginia, serving on the committee of seven, including Chief Justice Marshall, ex-President Madison, John Randolph, Watkins Leigh, and others, who made the draft of that instrument. **II. Philip Pendleton,** an American poet, son of the preceding, born at Martinsburg, Va., Oct. 26, 1816, died Jan. 20, 1850. He graduated at Princeton college in 1834, and returning to Virginia, studied law in the office of his father, was admittted to the bar, and married before he was 21. At college the greater portion of his time had been given to the study of poetry and belles-lettres, and he always took more pleasure in literary pursuits than in his profession. He published several poems in the "Knickerbocker" magazine, and on the establishment of the "Southern Literary Messenger" became one of its contributors. His only publication in book form was "Froissart Ballads and other Poems" (1847). At the time of his death he was publishing serially the "Chevalier Merlin," a historical prose poem. **III. John Esten,** an American author, brother of the preceding, born at Winchester, Va., Nov. 3, 1830. After the removal of his family to Richmond in 1839 he was sent to school, and finally prepared himself for the bar, to which he was admitted in 1851. Having contributed stories and sketches to various periodicals, he published a novel, "Leather

Stocking and Silk" (1854), which was almost immediately followed by "The Youth of Jefferson" and "Virginia Comedians." In 1855 appeared "Ellie, or the Human Comedy," in 1856 "The Last of the Foresters," and two years later "Henry St. John, Gentleman." This series of fiction presents many phases of life in Virginia. During the civil war he served on the staff of different confederate generals until the close of the contest, and wrote a "Life of Stonewall Jackson" (1866). He resides on a farm near Winchester, Va. His later works are: "Wearing of the Gray" (1867); "Mohun, or the Last Days of Lee and his Paladins" (1868); "Hilt to Hilt, or Days and Nights in the Shenandoah" (1869); "Hammer and Rapier" (1870); "Out of the Foam" and "Life of Robert E. Lee" (1871); "Doctor Vandyke" (1872); and "Her Majesty the Queen" (1873).

COOKERY, the preparation of food by dressing, compounding, and the application of heat. Posidonius was of opinion that the culinary art followed immediately the discovery of fire, and that it was at first an imitation of the natural process of mastication and digestion. There are frequent allusions to cooking in the Bible and in the oldest writings of all nations. In the East, the land of spices, the taste was first tempted by carefully wrought compositions and condiments, and the first great feasts were given. It was the custom of the ancient Egyptians, as at present in oriental and tropical climates, to cook the meat as soon as killed, with the view of having it tender. Beef and goose constituted the principal part of the animal food, though the kid, goat, gazelle, duck, teal, and quail were also well known. Mutton was excluded from a Theban table, and Plutarch says that no Egyptians except the Lycopolites would eat the flesh of sheep. The blood of animals was frequently received into a vase for purposes of cookery, and black puddings were popular in Egypt, as they afterward were in modern Europe, to the horror of the Moslems. Large supplies of fish were obtained from the Nile and Lake Mœris, and were brought to the table whole, boiled or fried, the tail and fins being removed. Herodotus says no Egyptian would taste the head of any species of animal. The vegetables which abound in Egypt made a large part of the ordinary food; they were eaten raw, stewed, boiled, or roasted in ashes. Bread was made either of wheat or of barley, and the dough was sometimes kneaded with the feet in a wooden bowl on the ground. Pastry was made to represent any object, according to the fancy of the confectioner, and was sprinkled with seeds of caraway, cummin, or sesame.—The Greeks raised every department of cookery to a high art. In the Homeric age royal personages prepared their own meats. Menelaus at the marriage feast of Hermione placed before the guests with his own hands the roasted side of an ox. Achilles, with the assistance of Patroclus, feasted the Argive leaders upon the shoulders of lambs, a fat doe, and a succulent pig, which were broiled on live coals and garnished with the entrails of oxen; dishes, according to Athenæus, "consecrated to the gods, and usual at all the feasts of the brave." They were contented in that age with plain roasts, seldom boiling their meat or dressing it with sauces. Professional cooks had come into existence before the age of Pericles. They could serve up a whole pig dexterously boiled on one side, roasted on the other, and stuffed with flavored and spiced thrushes, eggs, and various delicacies, so that the guest could not discover where the animal had been divided. To invent a popular cake or a poignant sauce was a worthy object of ingenuity and eruditjon. Aristoxenus after many trials succeeded in a peculiar way of seasoning hams, which were hence called Aristoxenians; as afterward the Roman Apicius, one of the three gastronomers of that name, devised a sort of cakes which were termed Apicians. Nearly all the Athenian dishes were prepared with a mixture of asafœtida or rue, and one of the most popular was a composition of cheese, garlic, and eggs. The Greeks and Romans extracted delicacies from the tough membranous parts of the matrices of sows, the flesh of young asses and young hawks, and from a great variety of sea fish, as the dog fish, star fish, porpoises, seals, and especially from two species termed the *echinus* and the *glociscus.* The Syracusans were especially noted for their culinary successes, while the Spartans, despising luxury of all kinds, had the term of reproach "to live like a Syracusan." A certain Sybarite, after tasting the Lacedæmonian black broth, declared himself no longer astonished that the Spartans were so fearless of death in battle, since the pains of dissolution were preferable to those of existence on such execrable food. The poet Archestratus, a culinary philosopher of Syracuse, travelled through the most fertile lands known to the ancients, crossing many seas, and passing through many dangers and hardships, in order to add edibles and potables from every climate to the Greek table luxuries. His "Gastrology," a didactic poem in which he promulgated the results of his researches, became the authoritative creed of Greek epicures. It was a favorite exercise of accomplished cooks, when rare and choice fish were wanting, to imitate their flavor, taste, and form so closely from inferior varieties that the most experienced gourmand could not distinguish the fraud. The Greeks excelled in sweetmeats, fruits, and the artistic ornaments and order of an entertainment, but the Romans in the more solid dishes. Simplicity of tastes and severity of manners disappeared during the latter part of the Roman republic, and under the empire luxurious gluttonies were indulged in at almost fabulous cost.—The more common Roman delicacies were pheasants, beccaficos, quails, partridges, oysters, sea eels, and Cecubian and Falernian wines. Rare fishes and birds were

objects of special luxury, and after Rome had learned from every neighboring country their best devices of cookery, native productions were despised, while at a single festival there would be served up peacocks from Samos, chickens from Phrygia, kids from Melos, cranes from Ætolia, tunny fishes from Chalcedon, pikes from Pessinus, oysters from Tarentum and Britain, mussel fishes from Chios, and dates from Egypt, with various foreign condiments. Some fishes were so costly that Cato once declared that "a city cannot endure in which a fish is sold for more than an ox." Curious artificial means were employed of raising delicacies for the table. According to the elder Pliny, snails were sometimes fattened till their shells would contain several quarts. Geese, peacocks, and fish were raised upon nourishment specially adapted to temper them as food, and swine were fattened on whey and figs. The supper, which was their principal meal, consisted of three courses: the first, of soups, lettuce, eggs, and honeyed wines; the second, of solid meats, ragouts, broiled viands, and fish; and the third, of crude fruits, preserves, tarts, and sweet dishes; the meals thus, according to a common saying, "beginning with eggs and ending with apples," whence the whole duration of anything was expressed by the phrase *ab ovo usque ad mala*. Lucullus gave feasts on a scale of inordinate magnificence, expending upon each 50,000 denarii (about $8,000). Galba breakfasted before daybreak at an expense sufficient to enrich a hundred families. Vitellius composed a single dish which cost 1,000 sesterces (about $40,000), of the brains of pheasants and peacocks, the tongues of nightingales, and the livers of the most precious fish; he once entertained his brother on 7,000 birds and 2,000 choice fishes; and his culinary expenses for four months amounted to about $25,000,000. The favorite supper of Heliogabalus was the brains of 600 thrushes. The favorite meat of the later Romans was pork, which held the place of honor on every luxurious table. "Hog in Trojan style" was, according to Macrobius, the masterpiece of the greatest artists. It was inherited from the Greeks, and was named from the circumstance that its interior contained myriads of thrushes, ortolans, and beccaficos, an image of the armed hosts enclosed in the Trojan horse. The manner of preparing it, long known to few, at length became public. The animal, after being bled under the shoulder, was hung up, and its intestines were drawn out through the throat; these were thoroughly washed, filled with hashed meat and a thick gravy, and then forced back into the body, which was also stuffed with small game. Half of it was then baked, the other half being covered and protected by a thick paste of barley meal, mixed with wine and oil; and the latter half was afterward boiled in a shallow saucepan. Young pigs were in especial demand, and pork, cooked in numerous styles, was eaten to such an extent that sumptuary laws were enacted limiting its consumption. In the mansions of the wealthier patricians, the kitchens were magnificently furnished with marble floors, pictures, and a profusion of ornaments. The culinary utensils, as gridirons, colanders, and dripping pans, were of bronze plated with silver; and the saucepans were of brass or earthenware, or sometimes of silver. Every article of food was served in bronze chafing dishes, "in order," says Seneca, "that no viand should be chilled." During the latter period of the empire there were not only schools of cookery, in which accomplished cooks acted as professors, but a profession was also instituted for the purpose of teaching the young patricians "how to masticate." The most curious relic of ancient literature on the subject is the *Deipnosophistæ*, or "Banquet of the Learned," of Athenæus, containing philosophical discussions on the history and quality of nearly every dish known to the Romans.—After the descent of the barbarians southward in the 5th century, cookery, like learning, retired into convents. The good cheer of the monks and the secular clergy at that period, and in the centuries immediately succeeding, is frequently alluded to in the early European poems and romances. In the 10th century refined cookery reappeared in Genoa, Venice, Florence, Milan, and other free cities of Italy, in which great fortunes had been made by commerce. It became more widely cultivated at the period of the renaissance, and flourished with eloquence, poetry, and painting, under the protection of the houses of Este and Medici, of Leo X. and the cardinals. The discovery of America and of the passage to the East Indies around the Cape of Good Hope contributed much to its development by enlarging the number of gastronomic productions, and especially by furnishing better seasoning than had before been known. The ancients had made use chiefly of cummin, mint, saffron, garlic, and oxymel; to these were now added cinnamon from Ceylon, vanilla from Mexico, cloves and nutmegs from the Molucca islands, pepper from Java, and allspice from the Caribbees. In the reign of Henry II. the elegant delicacies of Italian cookery were introduced into France by the train of cooks which followed Catharine de' Medici. About the same time several northern cities distinguished themselves by their gastronomic specialties: Mentz and Hamburg, by their hams; Strasburg, by lard and smoked sausages; Amsterdam, by herrings; Hamburg, by smoked beef; Ostend, by oysters; Périgueux, by truffles; and Chartres and Ruffec, by pies. The Britons were generally simple in their diet, with no higher culinary attainment than that of bruising their grain in a mortar; the Saxons were likewise savages in gastronomy, rejoicing in distilled barley and half-cooked game; the Danes were more hospitable, voracious, and bibacious, carousals being almost a part of their religion; but the Normans were the first to introduce in Britain the delicate refinements of

the art. The chief cook and his subordinates were officers of high consequence in the train of William the Conqueror. The monasteries of England were soon after famous for their luxuries, and in the reign of Henry II. the friars of St. Swithin complained to the king that the abbot had withdrawn three of the thirteen courses usually accorded them. Chaucer in his "Canterbury Tales" often mentions the good fare and skilful tastes of the clergy. In 1541 Archbishop Cranmer determined to regulate the culinary expenses of the clergy by an edict, and limited the archbishops to six dishes of meat (or of fish on fish days), the bishops to five, and the lower orders to four or three. The number of fowls and fish to be served in a dish was also detailed. The English nobility began to rival the Romans in expensive entertainments soon after the return of the crusaders, who during their travels had been made acquainted with oriental luxuries. Among the choicest dishes of that era was the peacock, generally served with the feathers of the tail unplucked and spread out to their fullest extent. In the reign of Elizabeth the mediæval style of cookery attained its zenith. Cooks were then classical scholars, and the heathen divinities were represented at every festival. Shortly after the Elizabethan period, a considerable alteration took place in the domestic economy of the nobility. Early hours and stricter habits were enjoined.—In France, the Gauls when first discovered subsisted chiefly on acorns and roots. Conquered by Cæsar, they speedily acquired the habits of their victors; and the Normans early attained great proficiency in the arts of luxury. In the latter part of the 14th century flourished the celebrated Taillevant, *chef de cuisine* for Charles V. and VI., from whom we have the recipe for a famous dish of that epoch called *galimafrée:* "Dismember a chicken, and cook it with wine, butter, verjuice, salt, pepper, nutmeg, thyme, laurel, and onions. When sufficiently cooked, add to the gravy some *cameline*" (a sauce composed of butter, cinnamon, ginger, allspice, grains of paradise, bread crumbs, and aromatic vinegar). Spices being very expensive at that period, a great consumption was made of them through vanity. In the reign of Louis XII. a company of *sauciers* obtained a monopoly for making sauces; and a company of *rôtisseurs*, for cooking meats on the spit. French cookery was of a sumptuous character in the reign of Louis XIV., and the table of the king rivalled in delicacy that of the great Condé, over which presided Vatel, who in despair at the tardiness of a dish committed suicide, and whose eulogy was written by Mme. de Sévigné. In the reign of Louis XV., especially under the regency, flourished Sabatier, Robert, Laguipierre, and other masters of the art, who introduced salutary improvements. Small supper entertainments, models of delicacy, savor, and elegance, and without superfluous show, came into fashion, and the great houses established what was termed the *petite cuisine*, which is still flourishing. The era of the revolution threatened to abolish with the privileges of the nobles the refinements of cookery, and famed culinary artists found themselves suddenly turned into the street. They instituted restaurants, which were received with favor by the citizens, and in which the art made progress under the directory and the consulate, till it was revived with new splendor in wealthy houses under the empire. Among the most illustrious recent French cooks are Boucher, Lasnes, Leiter, Delauny, Borel, Véry, Soyer, and Carême. The last converted the art into a science, made taste yield to chemistry, and the kitchen became instead of a workshop a laboratory. His works on the art of cookery are unrivalled.—The natural elements of food are found throughout the vegetable and animal kingdoms. The principal processes are boiling, roasting, frying, broiling, and baking. The great object in cooking meats is to retain as much as possible of their natural juice. Hence, when boiled they should be plunged at first into boiling water, that their outer part may contract and become impenetrable. On the other hand, the meat for soup should be put into cold water and gradually heated. It has been observed that hard water is better for boiling mutton, and soft water for vegetables. By boiling mutton loses one fifth of its weight, and beef one fourth; by roasting they each lose one third. Frying is the least healthful of all the operations. Broiling, by which the surface is suddenly browned and hardened and the juices retained, is the most eligible style for those who wish to invigorate themselves. Baking renders meat very savory and tender, not only by retaining the juices, but also by not permitting the escape of the fumes; but it causes greater retention of the oils, and therefore renders meats less easily digestible. The size and other conditions of a joint, or rather piece, are to be skilfully considered in cooking it. There are four principal French sauces, *l'Espagnole*, *la veloutée*, *l'Allemande*, and *la Bechamel*, two of them brown and two white, forming the bases of almost every other sauce. Among national dishes are the roast beef, beef steak, and plum pudding of England, the salt beef of Holland, the *Sauerkraut* of Germany, the *caviare* of Russia, the *pilau* of Turkey, the *polenta* and *macaroni* of Italy, and the *garbanzos* and *olla podrida* of Spain.—An acquaintance with the arts of cookery may be obtained from the cookery books, which abound throughout the civilized world. The oldest of these in modern times that has been preserved dates from the second half of the 14th century; it is entitled *Le ménagier de Paris*, and was written by a citizen of that city named Le Sage. Moral counsels are mingled in it with very full and curious culinary details. Another book by Taillevant, royal cook of France, dates from about 1392, and passed through eight editions

between 1480 and 1602. An excellent Italian treatise on cookery by Bartolommeo Scappi, chief cook of Pope Pius V., was published in 1570. Among the numerous cookery books which are in use and authority at the present time are Rumohr's edition of König's *Geist der Kochkunst* (Stuttgart, 1832); Otto's *Praktische Anleitung zur Kochkunst* (Leipsic, 1842); Carême's *Art de la cuisine française au XIX. siècle*, also his *Pâtissier pittoresque* and *Cuisinier parisien* (Paris, 1854); Plumerey's *Entrées chaudes* (Paris, 1854); the *Dictionnaire général de la cuisine française;* "The Cook, or Ladies' Kitchen Directory" (London); Kitchiner's "Cook's Oracle;" "Encyclopædia of Domestic Economy," by Webster and Parkes (London, 1844; with additions, New York, 1845); the "Housekeeper's Receipt Book," by Miss Catharine E. Beecher (New York, 1845); Miss Leslie's "New Cookery Book" (Philadelphia, 1857); "The Modern Cook, a Practical Guide to the Culinary Art in all its Branches," by C. E. Francatelli, pupil of Carême, and late *maître d'hôtel* to the queen of England (with additions, Philadelphia, 1858); "The Modern Housewife," translated from the French of Alexis Soyer (New York, 1859); "What to Eat and How to Cook it," by Pierre Blot (New York, 1863); "Handbook of Critical Cookery," by Pierre Blot (New York, 1868); "Common Sense in the Kitchen," by Marian Harland (New York, 1871); and Alexandre Dumas's *Grand dictionnaire de cuisine* (Paris, 1873). Other works in illustration of the subject are *De Honesta Voluptate et Valetudine*, by the Italian ecclesiastic Platina (1473); the *Almanach des gourmands*, by Grimod de la Reynière (8 vols., Paris, 1803–'12); and the brilliant and amusing *Physiologie du goût*, by Brillat-Savarin (Paris, 1825).

COOKMAN, George G., an American clergyman, born in Hull, England, Oct. 21, 1800, died at sea in March, 1841. He received a careful education, and joined the Methodist church in 1820. Three years later he visited the United States on business connected with his father's firm, and while here resolved to enter the ministry. In 1825 he joined the Philadelphia conference, and in 1833 was transferred to the Baltimore conference, and afterward labored in various portions of Pennsylvania, New Jersey, Maryland, and the District of Columbia. In 1838–'9 he was elected chaplain to congress. On March 11, 1841, he embarked in the steamship President to visit his native land, and perished with that vessel. Of his numerous sermons and addresses only one small volume has been published, "Speeches" (New York, 1841).

COOK'S ISLANDS, or **Harvey Archipelago,** a group of islands in the Pacific, lying S. of Polynesia, between the archipelago of Tonga on the west and Tahiti on the east, in lat. 20° S., lon. 157° W. The largest are Mangeia, Atiou, Harvey, and Raratonga. They are inhabited by people of the Malay race, most of whom have been converted to Christianity by English missionaries. Raratonga is a centre of Protestant missions in the Pacific islands. The population is estimated at 11,500, of whom 5,000 belong to Mangeia, 3,500 to Raratonga, and 1,000 to Atiou.

COOK'S STRAIT, a passage separating the northern and middle islands of the New Zealand group. Its discovery by Capt. Cook dissipated the belief then prevalent that New Zealand was part of a great southern continent. It varies from 20 to 80 m. in width. Wellington and Nelson, two of the largest towns of the English colony, are on this strait, the shores of which are subject to occasional earthquakes.

COOKSTOWN, a town of Ireland, county Tyrone, situated on the Belfast and Northern Counties railway, 10 m. N. of Dungannon; pop. in 1871, 3,653. It contains a Protestant church, a Roman Catholic church, two Methodist and three Presbyterian chapels; and in the vicinity is the union workhouse. The flax market is among the largest in Ulster.

COOLEY, Thomas McIntyre, an American jurist, born at Attica, N. Y., Jan. 6, 1824. He began the study of law in 1842 at Palmyra, N. Y., but removed the next year to Adrian, Mich., where he was admitted to the bar in 1845. For a time he edited a newspaper, "The Watch Tower." In 1857 he was appointed by the legislature to compile and publish the laws of the state, and in 1858 he was chosen reporter of the decisions of the supreme court. He held this office seven years, during which he published eight volumes of reports, which were followed by a digest of all the reports of the state. In 1859 the law department of the Michigan university was organized, and he was chosen one of the board of professors. He removed to Ann Arbor, where he resides, holding the office of dean in the law faculty. In 1864 he was elected to fill a vacancy on the bench of the supreme court of the state, and in 1869 was elected to that office for the full term of eight years. In 1868–'9 he held the position of chief justice. He has published a treatise on "The Constitutional Limitations which rest upon the Legislative Power of the States of the American Union" (1868; 2d ed., enlarged, 1871), and editions, with copious notes, of Blackstone's "Commentaries" (1870), and of Story's "Commentaries on the Constitution of the United States," with additional chapters on the new amendments (1873). He has during his judicial career given many important opinions, some of them upon great constitutional questions. Among these is one in 1870 against the right of cities and towns to raise money by public tax in aid of railways and private corporations.

COOLY (Hindostanee, *kûli*, day laborer), a term applied by Europeans to laborers in the East Indies, China, and Japan. It has become familiar chiefly in a restricted sense, denoting those eastern laborers imported for work upon tropical plantations, either under contract for

a term of years, as in the case of the British colonies, or by force and fraud, as in the case of Cuba and Peru. The term is not commonly applied to the free Chinese immigrants into the United States, Australia, &c. Coolies, in the restricted sense of the term, may be divided into two classes, viz.: those from India, and those from China.—The first attempt at the employment of Indian coolies appears to have been made in British Guiana about the time of the full emancipation of the slaves in 1838. A ship load of coolies was brought over in that year from Calcutta by private enterprise, but the experiment was not successful. The immigrants suffered greatly from diseases incident to change of life and climate, particularly from the bites of the chigo and other insects, which from neglect produced ulcers affecting life and limb. The mortality became so great as to lead to public investigation of their case, which caused great excitement in England, and the British Indian government interfered to stop the emigration of coolies. The urgent solicitations, however, of the planters of British Guiana, Trinidad, and Mauritius obtained an order in council, Jan. 15, 1842, by which the emigration of Hindoos was allowed under certain strict regulations, including the appointment of emigration agents in India and the colonies, whose duty it was to look after the welfare and rights of the coolies. The vessels that transported them were also placed under strict control as to number of passengers, provisions, &c. The passage money was advanced by way of bounty from the colonial treasury, which sometimes obtained reimbursement from the planters. This branch of cooly emigration, occurring wholly within the British dominions, is under the restraint of law both at the point of embarkation and of landing. In speaking of the regulations and working of the system in the colonies, we refer particularly to Guiana, which may be taken as representing them all. In India the emigration is now governed by the Indian acts of 1864 and 1869, which provide for a resident colonial emigration agent, by whom the recruiting agents who visit the country districts are appointed. These recruiting agents are licensed by the protector of emigrants at Calcutta, who is appointed by the government. Each agent takes the recruits he has enlisted before the resident magistrate of the district to which he is assigned, for registration; copies of the register, stating age, sex, caste, former occupation, and the rate of wages in the colony, are given to the emigrant, and duplicates are sent to the colonial emigration agent. After registration the recruits are forwarded to the depot at Calcutta, where they are examined by the colonial agent and by surgeons, to ascertain their physical fitness. A surgeon accompanies each cooly ship, who makes return of the deaths and sickness on the passage. These regulations, while they have done much to prevent injustice and imposition upon the ignorant emigrants, are said to be frequently evaded by the recruiting agents, who misrepresent the rate of wages in the colony, the duties that will be required of the coolies, and the laws to which they will be amenable. Before embarkation the emigrants enter into a contract with the colonial agent to serve 7½ hours a day for a period of five years as agricultural laborers on any estate to which they may be assigned by the governor of the colony, in return for which they are to receive a house, garden ground, and medical attendance free of expense, and the same rate of wages as may from time to time be paid to unindentured laborers on the same plantations. After ten years' service they are entitled to a return passage. In the colony the coolies are under the control of the immigration department, which exercises a general supervisory and protective power over them during their term of service, and with respect to their indentures are governed by the consolidated immigration ordinance of 1864, as amended in 1868. Upon their arrival the immigration agent general and the health officer of the port are required carefully to inspect them, and to separate such as are not capable of agricultural labor from those who are. They are then allotted to estates by the agent general, under direction of the governor, according to the numbers applied for by the proprietors, the agent being enjoined by law not to remove children under 15 from their parents, nor to separate relatives. The coolies are then indentured for a period of five years to the proprietors to whom they have been allotted. At the expiration of this period they are in general at liberty to engage for themselves as independent laborers; but the policy of the law favors a reindenture, under the supervision of the emigrant agent general, which must be for another term of five years. For reindenturing the cooly receives a bounty of $50. The local law of Trinidad, however, permits reindenturing only from year to year. The minimum of labor required of an able-bodied cooly by the immigration ordinance is five days' work or five tasks a week, seven hours a day if employed at out-of-door work, and ten hours a day if in buildings. For failure to perform the duties imposed upon him, and for various petty misdemeanors, he may be fined not exceeding $24, or imprisoned with hard labor not over one month. He is liable to summary arrest if found without a pass more than two miles from the plantation on which he is employed, and when his indenture has expired he must be able to produce a "certificate of industrial service," importing the completion of his term, signed by the immigration agent; otherwise, though nominally free, he is liable to arrest and detention until identified. The remedies provided for the cooly against his employers seem to be inadequate, while the practical working of the law is still more unequal, since the immigrants possess no political power, which is in the hands of

a few, who are identified with the planting interest and control the magistrates. A principal difficulty which the cooly system has labored under is the inferior quality of the immigrants in many instances. In the eagerness of the planters to obtain coolies when the business commenced, they suffered themselves to be imposed upon by the parties employed in the collection of emigrants, who occasionally sent them the refuse of the cities instead of persons accustomed to agricultural labor. The former class turned beggars and vagabonds, and caused much annoyance and trouble. The small proportion of women among them, and the bad character in general of those imported, have led to immorality among the immigrants, while the sentiment of caste preventing them from intermarrying with the blacks, and the policy of the law fostering reindentures, have tended to keep them a distinct class in the community. A term of service in the colony, however, has been found to improve the coolies, who lose the cringing and slavish demeanor which characterizes them in India. In 1870 a commission was sent out from England to Guiana to investigate the system, from which it may be expected that further ameliorations will result. The Hindoos are nearly all employed on the sugar plantations. They are not so strong as the negroes, who do much of the heavier work, but are averse to continuous labor, nor so quick and intelligent as the Chinese. Their first savings are usually invested in a cow, or in the case of the women in silver ornaments, of which many accumulate a large amount. From the best attainable data, it appears that the average earnings of ordinary laborers (say three fourths of the whole number) are about 28 cents for each day's work, the coolies generally working four or five days a week. Women earn from 16 to 32 cents a day, but do not work so many days a week as the men. Children from 10 to 15 years of age earn from 8 to 16 cents a day. It is estimated that during 1870 wages amounting to over $2,000,000 were paid to coolies, including Chinese. The amount of money carried out of the colony by coolies returning to India, up to the end of 1872, is stated at over $800,000. The number of immigrant depositors in the British Guiana savings bank, June 13, 1870, was 1,817, and their deposits amounted to $138,425 13. Besides Guiana, the principal localities to which Indian coolies have been taken are the islands of the Mauritius, which from its proximity to India takes the lead in the number imported, Trinidad, and Jamaica. The following table exhibits the number arriving in each colony from 1843 to 1872, the number that returned between those years, and the number remaining at the respective dates, with their sex and condition:

PLACE.	Arrived.	Returned.	Remaining.	Males.	Females.	Indentured.	Unindentured.
Mauritius	352,785	104,311	225,607 (Dec. 31, 1868)	147,753	77,854	.....	.....
British Guiana	80,599	8,432	46,623 (June, 30, 1869)	33,614	13,009	37,066	9,557
Trinidad	44,697	4,542	16,385 (Sept. 30, 1869)	.....	.....	9,563	6,822
Jamaica	15,999	3,194	.....	.....	.....	.....	.....
All British West Indies	146,663	16,851	.....	.....	.....	.....	.....

Those remaining in Mauritius constituted more than two thirds of the whole population; 122,449 were employed on sugar estates. Those remaining in Guiana (nearly one third of the population) and in Trinidad include Chinese. Some coolies have also been taken to the French island of Réunion (formerly Bourbon), which, together with Port Natal, between 1857 and 1866, received 18,363 immigrants from India.—The second branch of cooly emigration, that from China, is mostly of a very different character. The first cargo of Chinese coolies was taken in a Portuguese ship from Macao in 1847 to Peru. They were induced to embark by the representation that they were going to Java. Of the 300 that left the port only 175 were landed, who were immediately placed upon a plantation in the interior. The experiment proving satisfactory to the planters, other cargoes were procured, and soon the Cuban planters also sought the same labor. But those first shipped not having returned at the appointed time, and rumors of the fraud that had been practised upon them having spread among the Chinese, it became impossible to obtain voluntary emigrants, and other means were resorted to. The traders organized bands for the purpose of kidnapping coolies, and ships called lorchas, equipped as men-of-war and carrying the Portuguese flag, were sent up the bays and rivers, capturing whole cargoes. Under the influence of cupidity, parents sold their sons, banditti their prisoners, and fugitives from justice bargained themselves away. The traffic carried civil war into the province of Quangtung; rival clans and families took up arms against each other and sold their prisoners to the traders; while the Chinese mandarins and village elders not only connived at these practices, but even for a small fee aided the capture. The example of Macao was soon followed by other ports, and in 1853 Hong Kong, Swatow, Canton, Amoy, Whampoa, Camsingmoon, and smaller places were engaged in the traffic. To the enormity of their capture was added the barbarous treatment of the coolies on the passage and after arrival at the destination. Crowded to excess upon the ships and poorly fed, they died by hundreds on the voyage, while on the plantations they were overtasked, whipped, and practically reduced to slavery. Mutinies both upon the plantations and on shipboard have been frequent, and great numbers have committed

suicide. In 1854, the enormities of the cooly traders coming to the ears of the British government, measures were taken to suppress the traffic at Hong Kong, and soon after British and German vessels were forbidden by their respective governments to engage in the trade. By the regulations at present in force at Hong Kong, which are carefully observed, every emigrant is questioned by the authorities to ascertain if he goes voluntarily. If he chooses to remain, he is permitted to do so upon payment of any advances that may have been made to him and any expenses that may have been incurred in his behalf. A heavy fine is imposed upon persons detaining a cooly against his will, and no one under 25 years of age is allowed to emigrate without the consent of his parents or guardians. The captain of every vessel carrying Chinese passengers is obliged before sailing to make a report of the size of his ship, the accommodations for passengers, the quantity and kind of provisions on board, and the route he intends to pursue; and he is required to carry a surgeon and a supply of medicine. Ship masters or agents must guarantee to the cooly all his legal privileges in the country to which he is taken, and the owners or agents of the vessel are placed under bonds to deliver the coolies at the port for which they are shipped. A register is kept of the name and occupation of every emigrant. The measures taken by the principal European powers, however, did not suppress the cooly trade, but merely restricted it to certain ports, and caused it to disguise itself under the name of the "contract system." These contracts bound the cooly to pay a certain sum per month, or to work a certain time, as a consideration for his passage money. But being unable to read the agreement, the coolies were imposed upon, and made to sign a contract for eight or ten years' labor, in cases where the passage money only amounted to $50. In fact the papers were usually signed in blank, and left to be filled out at the whim of the trader. It soon became evident that this system was a mere cover for the barbarities of the traffic before openly perpetrated, and in 1862 an act of congress was passed which confiscated any American vessel engaged in the transportation of Chinese coolies "to any foreign country, port, or place whatever, to be disposed of or sold, or transferred for any term of years, or for any time whatever, as servants or apprentices, or to be held to service or labor;" and citizens of the United States were forbidden, under penalty of fine and imprisonment, to engage in any manner in such transportation. Previous to 1866 some Chinese coolies were received in the British West Indies, but the convention of that year, in which the Chinese government stipulated that the coolies should be entitled to a back passage at the expiration of five years' service, practically put an end to the emigration to those colonies, since the planters would not accede to the terms. These coolies brought from Hong Kong were protected by the regulations at that port, and in the colony are governed by the same law as the Indian immigrants. The number arriving to the close of 1866 in British Guiana was 12,631; Trinidad, 2,645; all the British West Indies, 16,222. The cooly emigration from Hong Kong from 1861 to 1866 was as follows: To British West Indies, 4,207; Bombay, 2,307; Dutch West Indies, 1,318; Tahiti, 1,035; Honolulu, 789; total, 9,656. The cooly traffic is now, and in its worst form has long been, almost wholly confined to Macao. The ships employed are French, Peruvian, San Salvadorian, Portuguese, and Spanish, and the great markets are Cuba and Peru. In these countries the system seems to have been little if at all ameliorated. The first attempt to regulate the employment of the coolies in Cuba by law was made in the royal order of March 22, 1854, by which they were permitted to become domiciled in the island after the expiration of their term of service, and to obtain papers of citizenship, by complying with the laws for the time being in force on the subject. The greater number availed themselves of the privilege. A new ordinance, however, was issued July 7, 1860, by which it was made an essential condition and special clause to be inserted in every contract, that at the end of his term the cooly should make a new contract of the same character, placing himself under a master or guardian; otherwise he was obliged to leave the island within two months at his own expense. Detailed instructions for the application of this ordinance were made public Dec. 31, 1868; and on April 27, 1871, a royal decree was issued suspending immigration and authorizing the government to cause all Chinese whose terms of service had expired, and who had not renewed their contract, to leave the island at the public expense. This decree, which appears to have been dictated by the participation of the coolies in the insurrection, was not carried into effect. A meeting of planters was held at Havana Sept. 16, 1871, under the presidency of the political governor, to consider the subject of Chinese immigration, in connection with the order of April 27. The governor, in his report to the administrative council of the province, shows that the ordinance of 1860, the object of which appears to have been to retain in the island a body of acclimated agricultural laborers, has not worked well, because the coolies after their term of service escaped to the mountains, or evaded the law by obtaining surreptitiously the necessary police documents, or contracting with fictitious masters. On the other hand, if the ordinance were strictly enforced, he thinks the Chinese would rather emigrate to the United States than contract for a further term. He considers that the good of Chinese immigration overbalances the evil; that it alone can develop the agricultural resources of the island and repair the waste of the rebellion; and that the coolies should be domiciled

on the expiration of their term of service, and should have the right to acquire property under certain restrictions. He advises that, when the state of the island permits, the existing restrictions upon immigration should cease. These views appear to be much more enlarged and liberal than those generally entertained by the planters. In the latter part of 1872 the violation of the contracts with coolies in Cuba, in preventing them from leaving the island at the expiration of their term of service and compelling them to enter into new indentures, was made by the United States the subject of diplomatic representation to Spain. —Peru in 1856 issued a decree prohibiting the traffic "in the violent and cruel manner hitherto prevalent," and regulating the transportation and employment of coolies; but it has been systematically violated, even if not repealed. A recent proof at once of the ill treatment and mismanagement of the coolies, and of the desperate character of those imported, may be found in the riot that occurred in 1870 on the extensive cotton estates of Galpon and Pativilca, about 180 m. N. of Lima, which spread until it embraced 2,000 coolies, and cost the lives of 40 whites and 300 Chinese. In 1869 and 1871 petitions from the coolies in Peru, complaining of the imposition practised to induce them to emigrate, and of the cruelties suffered by them in that country, and asking for the appointment of a Chinese resident at Lima to protect their interests, were forwarded to Prince Kung through the United States ministers at Lima and Peking. The Chinese government in response issued a decree that no merchants of non-treaty powers should be allowed to open an office for hiring laborers, and prohibiting all natives from engaging themselves to such, or going to Macao for that purpose. An order was also issued suspending all emigration to Peru, and the representatives of foreign nations were requested not to permit their flag to be used in the transportation; the governor of Macao being at the same time directed to put a stop to the emigration from that port. When the news of these measures reached Peru, public attention was attracted, and fears were expressed that the importation of coolies would be entirely cut off. It was finally resolved to send an embassy to China, which sailed in the early part of 1873, for the purpose of negotiating general treaties of amity, commerce, and navigation, but with the special object of regulating and establishing the principles on which the immigration of Chinese shall hereafter be conducted, the Peruvian government being willing to extend to them all the guarantees given in the treaties with other Christian nations. The cooly importation in Peru has recently been monopolized by a company formed to carry on the trade; but in 1870 an association of planters, with a capital of $1,000,000, was organized for the purpose of importing their own laborers, with a view to a reduction of the cost. There has long been a large company at Havana engaged exclusively in the importation of coolies, and in 1871 an association of rich planters, with a capital of $1,000,000, was formed in that city to import them for use on their own plantations. The present shipments from Macao consist of prisoners taken in the clan fights, of villagers or fishermen kidnapped by the lorchas, and of those who have sold themselves to pay their gambling debts. There are established cooly brokers in the city, who have a depot or private jail in which the coolies are kept until a cargo is obtained, when they are sold to the highest bidder, bringing from $10 to $27 apiece. They are all forced to sign a contract to serve eight years, for $4 a month and two suits of clothes a year; in Cuba these contracts usually bring about $400 each. In Peru coolies are sold for $350 to $450 apiece, and cost $60 to $80 each delivered at Callao. In Cuba they are mostly employed on sugar plantations; in Peru they are taken to the plantations in the interior, and are also employed on the Chincha and other guano islands. In both countries the mortality is great. In 1870 and 1871 several cases of barbarity on cooly ships occurred, which were made the subject of representation to the governor of Macao by the United States consul at Hong Kong. The only restriction upon the traffic at the former port appears to have been the prohibition of the transportation of coolies in vessels belonging to nations not having treaties with China nor employing cooly labor. A return passage was in 1873 secured to the cooly in the contract of service, and toward the end of that year the traffic was prohibited by proclamation. In May, 1871, Chief Justice Smale, of the supreme court of Hong Kong, in the case of a cooly charged with piracy for having participated in the mutiny on the French ship Nouvelle Penelope, Oct. 4, 1870, in which part of the crew were murdered, declared the cooly traffic, as carried on from Macao, to be the slave trade, and therefore itself piracy, and the rising of coolies to obtain their liberty to be justifiable.—The table given on the following page, compiled from the recent work of Mr. Russell H. Conwell ("Why the Chinese emigrate," &c., Boston, 1871), gives the most complete and accurate statistics attainable of the cooly traffic, from 1847 to 1870. Very few if any of the large number transported have returned to China. In 1869 there were 34,420 coolies in Cuba, and it is estimated that there are about 50,000 in Peru. According to the report of the political governor mentioned above, the number of Chinese arriving in Cuba from June 3, 1847, when the first cargo was received, to Oct. 10, 1871, was 109,029, costing $37,081,280, or $1,545,053 a year. Since the breaking out of the insurrection the importation has fallen off, only 2,715 coolies having arrived at Havana during 1870–'71, while in 1866 15,517 were shipped to that port from Macao. During the year ending Sept. 30, 1871,

9,201 Chinese were imported into Callao, and entered at the custom house at the value of $3,680,400; in 1872 over 13,000 were imported. About 7 per cent. of those embarked die before reaching Callao. According to Peruvian reports, from 1860 to 1872, 192 vessels with 80,354 coolies, were despatched from Macao to Peru, of whom 3,227 perished from shipwreck, and about 5 per cent. from sickness and suicide. In addition to the British West Indies, a few coolies, not included in the table, have been taken to the lesser Philippine islands and some other localities. In 1872 the government of Costa Rica gave permission for the introduction of Chinese coolies into that country, and the first cargo arrived at Punta Arenas Jan. 30, 1873, consisting of 654 coolies, 31 having died on the voyage. (For free Chinese emigration, see China.)—Under this head may be mentioned the employment, within a few years, of South sea islanders as laborers upon cotton and sugar plantations in Queensland, and in the Feejee and Samoa or Navigator's islands, and Tahiti. They are taken chiefly from Savage island, the Gilbert group, Banks islands, and some others. The procuring and employment of these islanders was early regulated by local law in Queensland. A colonial agent is sent with each ship, and a strict investigation is made upon its arrival. The laborers seem to be well treated, and in general to have been properly obtained; many after the expiration of their term of service have gone home, and returned to work again in the colony. Those employed in the Feejee islands and Tahiti, however, are treated with great cruelty, and are obtained by force and fraud, vessels being fitted out to kidnap the islanders, or purchase the prisoners taken in the tribal wars of the natives. After the establishment of the Feejeean government of 1871, it promised to take measures to regulate the traffic, but these promises appear not to have been fulfilled. The vessels employed in procuring the islanders are mostly British. In the early part of 1872 an act of parliament was passed "for the prevention and punishment of criminal outrages upon natives of the islands in the Pacific ocean," and several cruisers were sent to enforce it. Early in 1873 three vessels were seized by virtue of this act, while engaged in kidnapping Polynesians.

COOMASSIE. See Koomassie.

COOPER, a central county of Missouri, bounded N. by Missouri river, and intersected by the Lamine, which is navigable from its mouth to the Blackwater; area, 558 sq. m.; pop. in 1870, 20,692, of whom 3,352 were colored. The surface is hilly or moderately undulating, and occupied in some places by prairies. The soil requires little labor for cultivation, and the mineral wealth is said to be inexhaustible. Mines of bituminous and cannel coal are worked with profit in various quarters; iron and lead ores are extracted from veins near the Lamine; there are several quarries of marble and hydraulic limestone; and from the vicinity of Moniteau creek is obtained a kind of sand used in the manufacture of flint glass, and especially valuable on account of its rarity. The Pacific railroad of Missouri crosses the S. W. corner, and the Booneville branch traverses the county. The chief productions in 1870 were 385,696 bushels of wheat, 1,210,533 of Indian corn, 412,809 of oats, 68,052 of potatoes, 11,579 tons of hay, 227,001 lbs. of butter, 78,571 of wool, and 34,731 of tobacco. There were 6,971 horses, 2,607 mules and asses, 5,383 milch cows, 9,628 other cattle, 21,208 sheep, and 43,813 swine; 5 grist mills, 6 saw mills, 9 manufactories of carriages and wagons, 3 of bricks, 3 of stone and earthen ware, 1 of tobacco and snuff, 1 leather-currying, and 3 wool-carding and cloth-dressing establishments. Capital, Booneville.

COOPER, Anthony Ashley. See Shaftesbury.

COOPER, Sir **Astley,** an English surgeon, born at Brooke in Norfolk, Aug. 23, 1768, died in London, Feb. 12, 1841. His father was curate of the village of Brooke, and his mother, who belonged to the Paston family, was a popular writer in her day. His aptitude for the profession in which he became famous was first shown when he was but 12 years old. A foster

brother met with an accident which tore open his thigh and wounded the artery, and young Astley saved his life before a surgeon could be obtained by binding a handkerchief tightly above the wound. In 1784 he was sent to London to study under the direction of his uncle, William Cooper, the senior surgeon of Guy's hospital, who placed him under the care of Mr. Clive, surgeon of St. Thomas's hospital. At the age of 17 he was admitted a member of the physical society; and having afterward spent some time in Edinburgh studying with Drs. Gregory and Cullen, he was appointed demonstrator of anatomy at St. Thomas's hospital. In 1791 he was associated with Mr. Clive in delivering the lectures on anatomy and surgery. The next year the lectures were divided, Clive confining himself to anatomy, while Cooper devoted himself exclusively to surgery. About this time he married a lady of fortune, and in 1792 he was appointed professor of anatomy at Surgeons' hall, and was reappointed in 1794 and 1795. His first literary productions were two papers in a volume of "Medical Records and Researches" (1798). On the death of his uncle in 1800 he succeeded him as surgeon of Guy's hospital. In this and the following year he read before the royal society two papers on the effect of destroying the membrane of the tympanum, with an account of an operation for the cure of a particular species of deafness, which won the Copley medal for 1802. In 1805 he was elected a fellow of the royal society, and the same year took a prominent part in the formation of the medico-chirurgical society. Having devoted much attention to cases of hernia, he published in 1804 the first part and in 1807 the second part of his celebrated work on that subject. In 1806 he made the first attempt to put a ligature on the carotid artery, and though the case terminated unfavorably, it introduced a bold operation which has since proved successful in many cases. By this time his reputation was established, and in addition to his duties in the hospital and his numerous investigations in a laboratory and dissecting room of his own, he had one of the largest private practices ever enjoyed by a surgeon, his professional income for the year 1813 being no less than £21,000. He introduced a certainty and daring into surgical practice which was never before known. In 1817 he performed the boldest operation ever recorded, that of tying up the subclavian aorta. It resulted unfavorably, but the circumstances justified the experiment. In 1818 he began the publication of a series of medical essays in conjunction with one of his pupils, Mr. Travers, but the plan was given up after two parts of the work had appeared. He was consulted by George IV. in 1820, and in the following year removed a tumor from the king's head, for which he was rewarded a few months later with a baronetcy. In 1822 appeared his work on "Dislocations and Fractures," which showed a great advance in the understanding and treatment of cases of this kind. In 1825 he was obliged from ill health to discontinue his lectures and resign the office of surgeon at Guy's hospital; and the death of his wife in 1827 led him to give up practice and retire to his country estate at Gadesbridge. He soon tired of inactivity, and in 1828 returned to London, married again, and was appointed sergeant surgeon to the king. His health being in a great measure restored, he resumed his practice and his studies, and in 1829 began the publication of his "Anatomy and Diseases of the Breast," which was not completed till 1840. In 1830 appeared a treatise on the "Structure and Diseases of the Testicle," and in 1832 one on the "Anatomy of the Thymus Gland." He was elected president of the college of surgeons in 1827 and again in 1836, vice president of the royal society in 1830, and a member of the French institute in 1832; and among other honors he received the degrees of D. C. L. from Oxford and LL. D. from Edinburgh university. Though he lived expensively and is said to have been very generous to his poor relations, he left a fortune estimated at £500,000. He bequeathed £100 a year to be given every third year to the author of the best essay on some surgical subject. He was buried at his own request beneath the chapel of Guy's hospital. A colossal statue by Bailey has been erected to his memory in St. Paul's cathedral. His nephew, Bransby Blake Cooper, F. R. S., published a "Life of Sir Astley Cooper, Bart., interspersed with Sketches from his Note Book," &c. (2 vols., London, 1843).

COOPER, James Fenimore, an American novelist, born at Burlington, N. J., Sept. 15, 1789, died at Cooperstown, N. Y., Sept. 14, 1851. His father was Judge William Cooper, a man of great energy and high social position, and his mother was the daughter of Richard Fenimore, who belonged to a New Jersey family of Swedish descent. Judge Cooper, owning a large tract of land near Lake Otsego in central New York, established the settlement of Cooperstown, and moved thither with his family in 1790. In this wild frontier region the future novelist spent his boyhood. At the age of 13 he was sent to Yale college, but remained there only three years, when he entered the United States navy, where he continued six years, attaining the rank of lieutenant, and acquiring an experience which he found useful in his literary career. In 1811 he married a sister of Bishop De Lancey of western New York, and soon after resigned his commission and removed to Mamaroneck, a few miles from the city of New York. Declaring his belief that he could improve upon the popular novels of the day, he set about making the experiment, and produced "Precaution," a story of country life on the English model, which was published anonymously in 1819, at his own expense, and attracted little attention. In 1821 appeared "The Spy, a Tale of the Neutral Ground." It

was founded on incidents of the revolution, introduced some historical characters, and was written with so much power and originality that it gained a remarkable popularity at once, not only in this country but in Europe, being translated into almost all the continental languages. It was followed two years later by "The Pioneers," in which are introduced many exciting incidents of frontier life and glowing descriptions of forest scenery. It is the first in order of publication of the famous "Leatherstocking series." "The Pilot," the first of his romances of sea life, appeared also in 1823, being prompted, it is said, by the inaccuracies in the nautical incidents and descriptions of Scott's "Pirate," which had been recently published. This outstripped even "The Spy" in the popular enthusiasm which it excited. "Lionel Lincoln," another story of the revolution, which was comparatively unsuccessful, was published in 1825, followed the next year by "The Last of the Mohicans," in which Cooper continued his fascinating delineations of Indian character and of adventure among the pioneers in the American wilderness. In 1827 he went to Europe, where he remained six years, residing successively in the principal cities and continuing his literary labor. During his first year abroad he published "The Red Rover," the second of his sea stories, and "The Prairie," another of the Leatherstocking tales. To correct the numerous false impressions regarding American characteristics which he found prevailing in England, he published in 1828 "Notions of the Americans, by a Travelling Bachelor," purporting to be a book of travel in the United States. The next year appeared "The Wept of the Wish-ton-Wish," and in 1830 "The Water Witch." He was in Paris at the breaking out of the revolution of 1830, and took great interest in the changes then going on. Soon after this he replied to an article in the *Révue Britannique* severely criticising the government of the United States, and became involved in a controversy in which he wrote a series of letters in the *National* newspaper, defending his country against numerous slanders and misrepresentations. During the same period he wrote "The Bravo" (1831), a novel the scene of which is laid in Venice, and which the author considered his masterpiece. This and his two next works, "The Heidenmauer" (1832) and "The Headsman of Berne" (1833), were intended in part to illustrate his political views, which had been developed in the newspaper controversy in Paris. These discussions were read with interest at home and excited much criticism, not all of which was favorable to the novelist. On his return in 1833 he published "A Letter to my Countrymen," in which he gave an account of the controversy, and complained of the censures which had been passed upon it in this country, and of the general deference paid to foreign opinion. This was followed in 1835 by "The Monikins" and "The American Democrat," in which he satirized the failings of his own countrymen, and gave occasion to fierce assaults upon himself in the newspapers. These were multiplied and intensified by his "Homeward Bound" and "Home as Found" (1838), in which the newspaper editor was caricatured, and the satire upon American peculiarities continued. The strictures of the press were not confined to severe criticism upon the author, but in some cases degenerated into personal abuse, which led him to commence a remarkable series of libel suits. These involved a great expenditure of time and money, but served to fix more clearly than before the responsibility of journals in matters of libel. He says in one of his letters, "I have beaten every man I have sued who has not retracted his libels." During this strife with the newspapers he continued his literary work. He had already published the results of his observations in Europe in the "Sketches of Switzerland" (1836) and "Gleanings in Europe," "France," and "Italy" (1837–'8). In 1839 appeared his "Naval History of the United States," which served to increase the attacks already mentioned. Cooper now returned to the field of fiction, and sent forth in rapid succession "The Pathfinder" and "Mercedes of Castile" (1840), "The Deerslayer" (1841), "The Two Admirals" and "Wing and Wing" (1842), "Wyandotte, or the Hutted Knoll," the "Autobiography of a Pocket-handkerchief," and "Ned Myers" (1843), and "Afloat and Ashore" and "Miles Wallingford" (1844). In 1844 he also published a "Review of the Mackenzie Case," in which he severely censured the course of the commander of the Somers. The same year he became interested in the anti-rent controversy, and began the series of "Littlepage" tales for the purpose of denouncing the anti-rent doctrines, which he regarded as dangerous to society. These consisted of "Satanstoe" and "The Chainbearer" (1845), and "The Redskins" (1846). Maintaining as they did the unpopular side of the question, the real merits of these works were in a measure overlooked. In 1846 he also published "Lives of Distinguished American Naval Officers," forming a fitting companion to the "Naval History." In 1847 appeared "The Crater, or Vulcan's Peak," a romance introducing supernatural characters and incidents, the scene of which was on a reef in the Pacific ocean, and in 1848 "Oak Openings, or the Bee Hunter," a story of woodland life. The last of the series of stories of the sea were "Jack Tier, or the Florida Reefs" (1848), and "The Sea Lions, or the Lost Sealers" (1849). The last of all his novels was "The Ways of the Hour," intended to expose the defects of trial by jury (1850). He had in press at the time of his death a historical work, "The Towns of Manhattan," and was contemplating a sixth Leatherstocking tale. He died somewhat suddenly of dropsy. His later novels did not gain the popularity accorded to some of the earlier ones. The entire series of his novels has been

published in various editions since his death, and they have taken their place at the head of American fiction. Several of them have been translated into nearly all the European and some of the oriental languages.—Personally, Mr. Cooper was a noble specimen of a man, possessing a massive and compact form, a countenance strikingly marked with the indications of intellectual strength, and glowing with manly beauty. His published portraits, though imposing, by no means do justice to the impressive port and vivacious presence of the man. In his social traits, so far as his native reserve and strong predilections would permit, he was magnanimous, hospitable, and kind. Frank, generous, independent, and not over-refined either by native constitution or culture, enemies were as plentifully made as easily reconciled by his singular admixture of opposing qualities. His intellectual life was checkered by much the same variety of lights. There were the elements of genius, originality of invention, keen insight into character, and creative skill, shaded by defects both of original mental structure and of literary culture, not less conspicuous. But taken all in all, no American writer has attained a wider fame. —Susan Fenimore, his eldest daughter, born in 1815, is the author and editor of several popular works, chiefly descriptive of rural life. The first, "Rural Hours," was published in 1850, during the later years of Mr. Cooper's life, and won a permanent and honorable place in literature. It was followed in 1854 by "Rhyme and Reason of Country Life," a fine selection of choice descriptive passages, in prose and verse, relative to country life and its incidents, illustrated with suggestive and graceful notes, and introduced by a genial essay. An annotated edition of an English work, "The Journal of a Naturalist," was published in 1852; and in 1858 she wrote a little book for youth on the character of Washington, the proceeds of which were given in aid of the fund for the purchase of Mt. Vernon. Various popular contributions to periodical literature have also from time to time proceeded from her pen, though generally anonymous.

COOPER, Peter, an American philanthropist, born in New York, Feb. 12, 1791. His maternal grandfather, John Campbell, was an alderman of New York and deputy quartermaster general during the revolutionary war, and expended a considerable private fortune in the service of his country. His father was a lieutenant in the war of the revolution, after the close of which he established a hat manufactory. This period of Peter Cooper's life was one of great anxiety and hard labor, as his father was not successful in his undertakings, and had a large family to provide for. He attended school only half of each day for a single year, and beyond the knowledge thus gained his acquisitions are entirely his own. At the age of 17 he was apprenticed to the trade of coachmaking, and served out his time so much to the satisfaction of his master, that the latter offered to set him up in business, which he declined. He for some time followed his trade; next engaged in the manufacture of patent machines for shearing cloth, which were in great demand during the war of 1812, but lost all value on the declaration of peace; then in the manufacture of cabinet ware; then in the grocery business in the city of New York; and finally in the manufacture of glue and isinglass, which he carried on for 50 years. His attention was early called to the great resources of this country for the manufacture of iron, and in 1830 he erected extensive works at Canton near Baltimore. Disposing of these, he subsequently erected a rolling and wire mill in the city of New York, in which he first successfully applied anthracite to the puddling of iron. In 1845 he removed the machinery to Trenton, N. J., where he erected the largest rolling mill at that time in the United States for the manufacture of railroad iron, and at which subsequently he was the first to roll wrought-iron beams for fire-proof buildings. These works have grown to be very extensive, including mines, blast furnaces, and water power, and are now carried on by Mr. Cooper's family. While in Baltimore he built after his own designs the first locomotive engine constructed on this continent, and it was used successfully on the Baltimore and Ohio railroad. He took great interest in the extension of the electric telegraph, in which he invested a large capital. He served in both branches of the New York common council, and was a prominent advocate of the construction of the Croton aqueduct. His great object was to educate and elevate the industrial classes of the community. He early became a trustee of the public school society, and at the time of its being merged in the board of education was its vice president. He subsequently became a school commissioner; but feeling that no common school system could supply a technological education, he determined to establish in his native city an institution in which the working classes could secure that instruction for which he, when young and ambitious, sought in vain. In furtherance of this object the "Union for the Advancement of Science and Art," commonly called the "Cooper Institute," was erected in New York at the junction of Third and Fourth avenues, between Seventh and Eighth streets, covering the entire block, at a cost of over $650,000, to which Mr. Cooper has since added an endowment of $150,000 in cash. This building is devoted by a deed of trust, with all its rents, issues, and profits, to the instruction and elevation of the working classes of the city of New York. The plan includes regular courses of instruction at night, free to all who choose to attend, on social and political science, on the application of science to the useful occupations of life, and on such other branches of knowledge as will tend to improve and elevate the

working classes. It includes also a school of design for females, now attended by 200 pupils, a free reading room and library, resorted to by about 1,500 readers, galleries of art, collections of models of inventions, and a polytechnic school. The evening schools are attended by 2,000 pupils, mostly young mechanics, who study engineering, mining, metallurgy, analytic and synthetic chemistry, architectural drawing, and practical building. There are also for women a school of telegraphy, which in four years has sent out 307 operators, a school of wood engraving, and a school of photography, all of which are free and are well attended. These schools employ upward of 30 instructors. The receipts of the institute in 1872, from rents and interest on endowment, were about $37,000 and the expenditures $56,000. Mr. Cooper is now (1873), at the age of 82, still vigorous in mind and body, and devotes himself to works of charity and public benefit.

COOPER, Samuel, D. D., an American clergyman, born in Boston, March 28, 1725, died Dec. 29, 1783. He graduated at Harvard college in 1743, studied theology, and at the age of 20 succeeded his father in the Brattle street church, where he remained 37 years, gaining the reputation of one of the most accomplished orators and scholars of New England. He took an influential part among the patriots of the revolution, writing various pamphlets in opposition to the pretensions of Great Britain, and was the person to whom Dr. Franklin sent the letters of Hutchinson. He was one of the foremost in laying the foundation of the American academy of arts and sciences, and became its first vice president in 1780.

COOPER, Thomas, an American scholar and politician, born in London, Oct. 22, 1759, died at Columbia, S. C., May 11, 1840. He was educated at Oxford, afterward studied medicine and law, and was admitted to the bar and travelled a circuit for a few years; but being sent by the democratic clubs of England to the affiliated clubs in France, he took part with the Girondists, and was called to account for his course by Mr. Burke in the house of commons. He wrote a violent pamphlet in reply, the publication of which in cheap form for popular circulation was forbidden by the government. While in France he had learned the secret of making chlorine from common salt, and now became a bleacher and calico printer in Manchester, but his business was unsuccessful. He then came to America, and established himself in Pennsylvania as a lawyer. He opposed the administration of John Adams, and for a violent attack on the president in a Pennsylvania newspaper in 1799 was tried for a libel under the sedition act, and sentenced to six months' imprisonment and a fine of $400. The democratic party coming into power, he was appointed land commissioner for Pennsylvania in 1806. Being appointed to the office of judge, he became obnoxious to members of his own party, and was removed in 1811 on a charge of arbitrary conduct. He then successively occupied the chair of chemistry in Dickinson college, in the university of Pennsylvania, and in Columbia college, S. C., of which last institution he became president in 1820, and in which he discharged also the duties of professor of chemistry and of political economy. On his retirement in 1834, the revision of the statutes of the state was confided to him, and completed just before his death, in 10 vols. 8vo. Dr. Cooper was eminent for the versatility of his talent and the extent of his knowledge. His principal works are: "Information concerning America" (London, 1794); "An English Version of the Institutes of Justinian," contrasting the Roman and American jurisprudence (Philadelphia, 1812; 3d ed., 1852); "Tracts on Medical Jurisprudence" (Philadelphia, 1819); and "Lectures on the Elements of Political Economy" (Charleston, 1826). He was also a vigorous pamphleteer and an admirable talker.

COOPER, Thomas, an English chartist, born in Leicester, March 20, 1805. A shoemaker by trade, he became a schoolmaster, afterward a newspaper reporter, and in 1841 a leader of the chartists in his native town. He was imprisoned from 1842 to 1844 for having lectured in the Potteries during the riots in August, 1842. While in Stafford jail he wrote "The Purgatory of Suicides" and "Wise Saws and Modern Instances" (1845). He afterward published "The Baron's Yule Feast" (1846), "Triumphs of Perseverance" and "Triumphs of Enterprise" (1847), "Alderman Ralph" (1853), and "The Family Feud" (1854). He also edited the "Plain Speaker" and "Cooper's Journal," both penny weeklies. In 1855 he renounced the skeptical views which he had expounded in the latter publication, and has since lectured and preached in favor of Christianity.

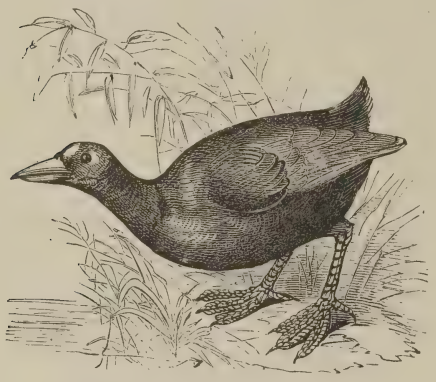
COOPER, Thomas Sidney, an English painter, born in Canterbury, Sept. 26, 1803. He early developed a talent for drawing, and was accustomed to sketch from nature without instruction. At the age of 17 he became scene painter to the Canterbury theatre, and during the next seven years he supported himself by scene painting and teaching drawing. In 1827 he visited the continent and settled in Brussels, where he married, and for several years derived a comfortable support from teaching and the proceeds of his pencil drawings. He made the acquaintance of Verboeckhoven, the Belgian animal painter, whose example strongly influenced him in devoting himself thereafter to landscape and animal painting. In 1830 he returned to England, and devoted several years to careful study from nature. His first picture, exhibited in 1833, attracted so much attention that he was commissioned to execute the noted landscape painting which is now in the Vernon gallery. This was the foundation of his subsequent success as an animal painter, in which

department he attained a high place, and in 1845 was elected an associate of the royal academy. He excels in groups of oxen, cows, sheep, or goats, the landscape backgrounds to which are subdued in tone, though in perfect keeping with the general character of the composition. For many years he painted in conjunction with F. R. Lee, who supplied the landscape.

COÖPERATIVE ASSOCIATIONS. See SOCIALISM.

COOPER RIVER, in South Carolina, rises in the central portion of Charleston county, and flowing S. E. unites with the Ashley below Charleston, forming the harbor of that city. It is navigable by small vessels for 30 m. to the Santee canal, 21 m. long, connecting it with the Santee.

COOPERSTOWN, a post village and the capital of Otsego county, N. Y., 60 m. W. of Albany; pop. about 1,800. Situated at the outlet of Otsego lake, which is embosomed in hills 400 ft. high, it presents some of the most beautiful and picturesque scenery in the state. The village is noted as having been the residence of James Fenimore Cooper, by whose father, Judge William Cooper, it was founded, and has of late years become a popular summer resort.



COORG, Koorg, or **Caduga,** a district of S. Hindostan, among the Western Ghauts, bounded N. by Canara and Mysore, E. by Mysore, S. by Malabar, and W. by Malabar and Canara, mainly between lat. 12° and 12° 45′ N., and lon. 75° 25′ and 76° E.; area about 1,600 sq. m.; pop. in 1871, 111,830. It is extremely rugged, mountainous in all parts, covered in some places with forests of sandal and other woods, but in many others overrun with jungle. The most noteworthy feature of the district is the artificial fortifications, the country being intersected by ramparts 15 to 25 ft. in height, and ditches 10 ft. deep and 8 ft. wide. These works are supposed to be very ancient, and in some places they are crowned with enormous trees. The soil is fertile; rice is cultivated for exportation, pepper, cardamoms, and other spices are produced, and great attention is paid to cattle-raising. The climate is temperate, and generally healthy. The inhabitants are Brahmans. It is the custom for brothers of the same family to have their wives in common. There are no manufactures except of coarse cloths for domestic wear. Mercara is the capital. Coorg was formerly an independent principality, and considerably larger than the present district known by that name. It was seized by Hyder Ali in 1773, and parcelled out among many petty chieftains; but in 1787 the son of the deposed rajah succeeded in expelling the invaders. In 1834 the territory was added to the possessions of the East India company. The chief commissioner of Mysore has also charge of the district of Coorg.

COÖS. I. The N. county of New Hampshire, bounded N. by Canada, E. by Maine, and W. by Vermont and Canada, and intersected in the E. part by the Androscoggin river; area, 1,950 sq. m.; pop. in 1870, 14,932. The White mountains occupy the southern part. Among these mountains the Saco river takes its rise, and in the extreme north are the sources of the Connecticut. Near the banks of this stream the soil is tolerably fertile. In the vicinity of some other smaller rivers the land is also cultivated, but the greater portion of the surface is hilly and unproductive. Its name is an Indian word signifying pines, with which a large part is covered. It is traversed by the Portland branch of the Grand Trunk railway of Canada, and the White Mountain railroad runs to the county seat. The chief productions in 1870 were 19,227 bushels of Indian corn, 185,674 of oats, 55,801 of buckwheat, 811,569 of potatoes, 40,795 tons of hay, 419,462 lbs. of butter, 63,666 of wool, and 208,574 of maple sugar. There were 3,147 horses, 5,119 milch cows, 2,259 working oxen, 6,360 other cattle, 14,766 sheep, and 1,463 swine; 39 saw mills, 4 tanneries, 12 manufactories of carriages and wagons, 1 of machinery, 2 of paper, 12 of saddlery and harness, 4 of sashes, doors, and blinds, 1 of shoe pegs, 40 of potato starch, and 3 of tin, copper, and sheet-iron ware. Capital, Lancaster. **II.** A S. W. county of Oregon, bounded W. by the Pacific; area, 1,500 sq. m.; pop. in 1870, 1,644, of whom 13 were Chinese. It is watered by Coös and Coquilla rivers. The Umpqua mountains are on the E. border. Coal and veins of gold and copper have been found. Coös bay furnishes a good harbor. A railroad is in progress from the bay to Roseburg, in the adjoining county. The soil is good, but lumber is the chief staple. The chief productions in 1870 were 2,802 bushels of wheat, 1,859 of Indian corn, 3,386 of oats, 1,182 of barley, 2,044 of peas and beans, 1,165 of potatoes, and 644 tons of hay. There were 347 horses, 949 milch cows, and 1,412 swine. Capital, Empire City.

COOSA, a central county of Alabamá, bounded S. W. by Coosa river; the former area was 860 sq. m., but a portion has recently been taken to form Elmore county; pop. in 1870, 11,945, of whom 3,394 were colored. The surface is hilly, and the soil very productive. The pasture lands are excellent, and perennial springs are found in almost all parts. Numerous small streams afford an abundance of water power. Lead and iron mines have been opened; statuary granite of very superior quality is found. In the northern part is an immense quarry of beautiful marble, extending through Coosa and Talladega into Calhoun county. The chief productions in 1870 were 36,066 bushels of wheat, 262,638 of Indian corn, 20,513 of oats, 30,508 of sweet potatoes, 3,893 bales of cotton, and 91,961 lbs. of butter. There were 1,406 horses, 1,184 mules and asses, 3,779 milch cows, 528 other cattle, 4,546 sheep, and 12,689 swine; 1 cotton mill, several flour and saw mills. Capital, Rockford.

COOSA, a river of Georgia and Alabama, 350 m. long. It is formed by the union of the Etowah and Oostenaula at Rome, Ga., flows S. W., and after passing the Ten islands in Alabama turns S. and S. E., and joins the Tallapoosa to form the Alabama in Elmore co., between Wetumpka and Montgomery. From Rome to the Ten islands in Alabama, and below Wetumpka, it is navigable by steamboats. Between the Ten islands and Wetumpka the shoals which obstruct the channel at short intervals prevent the passage of any vessels except flat-boats.

COOT, a lobe-footed bird of the order *grallatores*, family *scolopacidæ*, and genus *fulica*. In this genus the bill is shorter than the head, strong, straight, and elevated, forming a broad shield on the forehead; the wings are short;

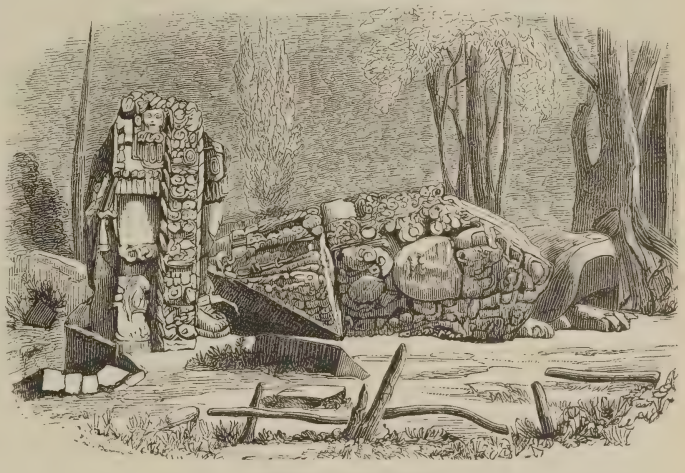
American Coot (Fulica Americana).

the tail is very short and rounded; the tarsi are shorter than the middle toe; the toes are long, united at the base, lobed on each side, the inner toe with two, the middle with three, and the outer with four rounded membranous lobes; the hind toe is lobed its whole length. There are about a dozen species of the genus, scattered over the world, migrating from north to south in winter. The American or cinereous coot (*F. Americana*, Gmel.) is about 14 inches long, with an extent of wing of 25 inches; bill long, the back 1⅓ inch; weight about 1 lb. The head is small, neck slender, body rather full; feet strong, tibia bare a little above the joint; the plumage is soft and blended. The bill is grayish white, with a dusky spot near the end; the general color of the upper parts is deep bluish gray, blackish on the head and neck, and olivaceous on the shoulders; the quills are grayish brown, with darker tips; edge of the wings, outer margin of first quill, tips of outer secondaries, and lower tail coverts, white; tail brownish black; under parts light bluish gray. They are found throughout North America, and in New England in the autumn, retiring south about November. Their favorite resorts are the borders of ponds and rivers lined with thick reeds, to which they can fly on the approach of danger; they swim, dive, fly, and run well; they rise, however, with difficulty, fluttering the wings and striking with the feet to assist; they fly high, with quick motion of the wings. They feed, especially in the morning and evening, near the edge of the water and in the open lands bordering on the streams and lakes. The food consists of aquatic insects and plants, mollusks, small fish, worms, seeds, and even tender grass and leaves. In the south they are seen in flocks of several hundred. They probably breed in the northern states; the nest, built of decayed vegetable matter and sticks, is placed near the water among the reeds; it is sometimes carried away by inundations, when it floats without injury to the eggs or displacing the female; the eggs are from seven to ten in number, ash-gray in color, spotted minutely with black, and the young take to the water as soon as hatched. A common name for this species is the mud hen. They are abundant in the New Orleans market in winter, and are much used as food by the poorer classes, who skin instead of plucking them.—In New England the name is improperly given to several species of duck, especially to those of the genus *oidemia;* among the species thus named are the scoter duck (*O. Americana*, Swains.), white-winged or velvet duck (*O. fusca*, Swains.), and black or surf duck (*O. perspicillata*, Flem.).

COPAIBA. See Balsams.

COPAIS, or **Topolias,** a celebrated lake in Bœotia, the largest in Greece, 47 m. in circumference. It is formed by the Cephissus and the numerous small streams which descend from the surrounding hills. Its waters empty into the Euripus through subterraneous passages in the surrounding limestone. (See Bœotia.)

COPAL, the resinous juice of the *rhus copallina* of Mexico and the *elæocarpus copalifer*



Copal (Rhus copallina).

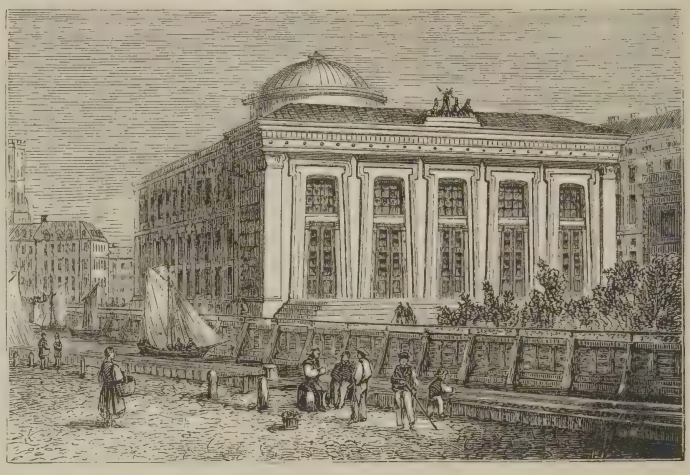
of India. It is obtained by the natives by cutting a notch in the tree, in which it collects.

Another variety of the copal tree is found on the coast of Guinea, where lumps of the resin are gathered from the sands by the negroes. Copal is of various colors, from a pale yellow hue to a dark brown, and of different degrees of transparency. It often includes insects and animal remains. It is harder than other gums, breaks with a conchoidal fracture, and has neither odor nor taste. An excellent and durable varnish is prepared from it. It melts with the heat of a spirit lamp, giving out an oily substance, and becoming deeper in color until it is converted into charcoal. Copal is not easily soluble in alcohol, the greater part merely swelling up and softening; but pulverized and then dried at a moderate heat, it dissolves in alcohol of 96 per cent. Camphor first dissolved in the alcohol increases its power of taking up the copal. It is much more soluble in ether, and the solution may be diluted with alcohol without the copal precipitating. Different kinds of copal are differently affected by ether; some dissolve readily, others with great difficulty. Varnishes of different qualities may be thus obtained by the same solvent. After ether, some of the volatile oils are the best solvents of copal, as the oils of rosemary, lavender, and spruce. The oils of petroleum and turpentine have little action on crude copal. When fused, it dissolves more easily, but produces inferior qualities of varnish. Its composition, according to Dr. Ure, is carbon 79·87, hydrogen 9, oxygen 11·1; being of hydrogen 7·6 in excess above the quantity necessary to form water with the oxygen. An excellent recipe for varnish is the following given by Böttger: 1 part of camphor is dissolved in 12 parts of ether; 4 of copal are then added, and allowed to swell in it, when 4 parts of anhydrous alcohol and $\frac{1}{4}$ part of rectified oil of turpentine are added. It is stated by Dr. Wight that on the Malabar coast a variety of this resin, called *piney dammar*, is made into candles which diffuse an agreeable fragrance, give a clear light with little smoke, and consume the wick without requiring snuffing.—A fossil copal is described in the books of mineralogy, which resembles the resin in its hardness, color, lustre, transparency, and difficult solubility in alcohol. It is found in the blue clay near London, and is called Highgate resin; and also in flattened drops on calc spar on the walls of a trap dike at an old lead mine in Northumberland. A similar fossil has been also obtained in the East Indies. The composition of the mineral is carbon 85·41, hydrogen 11·78, oxygen 2·67, ashes 0·136.

COPAN, a small town of Honduras, Central America, in the department of Gracias, 120 m. W. by N. of Comayagua, on a river of the same name, an affluent of the Motagua. It gives its name to the wonderful ruins in its vicinity, the remains of an ancient city, which cover a densely wooded tract more than 2 m. in length along the banks of the stream.

A Fallen Idol at Copan.

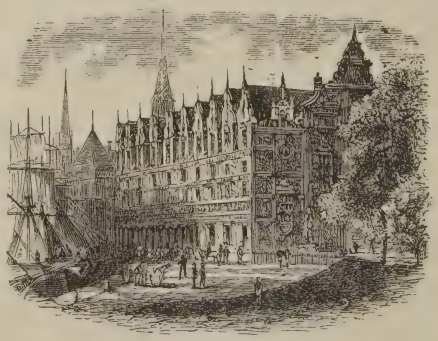
Among them are the walls of a vast building, 624 ft. long, supposed to have been a temple, a plaza paved with well squared stones, a tower or terrace with a grand stairway of many steps descending to the river, colossal monolithic statues elaborately carved, and other sculptures. These ruins excited the wonder of the Spanish conquerors, who sought in vain to learn something of their origin from the natives. They were described with great accuracy in 1576 by the licentiate Palacios. A full account of them is given in Stephens's "Central America." (See American Antiquities.)



COPARTNERSHIP. See Partnership.

COPE, Charles West, an English painter, born in Leeds in 1811. He is the son of an artist, studied in the royal academy, and in 1831 exhibited his first picture, the "Holy Family," which was purchased by Mr. Beckford. In 1843 his cartoon of the "First Trial by Jury" gained a prize of £300 in the Westminster hall competition; and in the succeeding year he obtained a commission to paint one of the six frescoes for the new house of lords. In 1844 he was elected an associate, and in 1848 a member of the royal academy. He also received commissions to execute additional designs for the new palace, illustrative of incidents in the history of England. His eight frescoes in the peer's corridor illustrate the historical incidents of the reign of Charles I.

Among his later productions are: "Parting of Lord and Lady Russell" (1861), "Convalescent," and "Scholar's Mate" (1862). He is equally successful in painting historical and domestic scenes.



COPE, Edward Drinker, an American naturalist and comparative anatomist, born in Philadelphia in 1840. He became professor of natural science in Haverford college, Pa., in 1864, and resigned from ill health in 1867, and devoted himself to zoölogy and geology. Since 1859 he has contributed to scientific journals more than 100 papers, among which are contributions to the herpetology of tropical countries; monographs of the ichthyology of Pennsylvania, Virginia, North Carolina, Michigan, &c.; "Primary Groups of Batrachia Anura" (1865); "On the Arciferous Anura" (1866); reports on the reptilia of the several exploring expeditions (1862–'8); "History of the Cetacea of the Eastern North American Coast" (1866); "Synopsis of the Extinct Cetacea of the United States" (1867–'8); "Systematic Arrangement of the Lacertilia and Ophidia" (1864), and "of the Class Reptilia" (1870); and "Origin of Genera" (1868). In 1868–'9 he investigated the greensand of the cretaceous formation of New Jersey, and discovered several new genera and species, which he described in "A Synopsis of the Extinct Batrachia, Reptilia, and Aves of North America" (4to, Philadelphia, 1869; published also in vol. xiv. of the "Transactions of the American Philosophical Society"). His paper on the "Systematic Relations of the Fishes," in the annual volume for 1871 of the American association for the advancement of science, is founded on the study of 1,000 skeletons, 800 of which were collected by the anatomist Prof. Joseph Hyrtl of Vienna, and are now in Prof. Cope's museum. His paper "On the Hypothesis of Evolution, Physical and Metaphysical," appeared in "Lippincott's Magazine" for July, August, and September, 1870, and is No. 4 of the "University Series of Valuable Lectures and Essays" (New Haven, 1871). In August, 1871, he read a paper before the American association for the advancement of science "On the Method of Creation, or the Laws of Organic Development," which he expanded in a series of four articles in "The Penn Monthly Magazine" for 1872. Besides the above, and other scientific papers, he has written reports on the "Extinct Vertebrates of the Eocene of Wyoming and Nevada" (1872), and on "New Vertebrata from the Tertiary of Colorado" (1873).

COPENHAGEN (Danish, *Kjöbenhavn*, merchants' harbor; Lat. *Hafnia*), the capital of Denmark, situated partly on the island of Seeland in the Baltic, and partly on the island of Amager; lat. 55° 41′ N., lon. 12° 34′ E.; pop.

The Thorwaldsen Museum.

in 1871, 181,291, all Lutheran, with the exception of 3,000 Jews, 1,100 Catholics, and about 1,000 of other sects. Besides several suburbs, it consists of three principal divisions, viz.: the old city or West End, the new city or Frederiksborg, on the island of Seeland, and Christianshavn, on the island of Amager. The city is protected by the fortress of Frederikshavn. The channel between the main island and Amager constitutes the harbor, which is very capacious. The city contains numerous public squares, churches, and hospitals, several theatres, an arsenal, exchange, and four royal palaces. The centre of the city is formed by the Kongens Nytorv, a large and handsome square, from which issue the

Exchange.

principal thoroughfares, the finest street being the Bredgade (broad street), which leads directly to the esplanade of the citadel. The castle or palace of Rosenborg, partly surrounded by a public garden, was commenced in 1604, but has long ceased to be a royal residence, and is devoted to the chronological collection of the Danish kings, one or more rooms being devoted to the reign of each, commencing with Christian IV. (1588–1648). The old palace of Christiansborg was at the time of its destruction by fire in 1794 one of the handsomest palaces in Europe. The new palace, opened in 1828, when partly finished, has never been used as a permanent residence, being reserved mainly for festivities and for the use of the *Things* or houses of parliament. It is situated on a little island bounded by the harbor and by canals, crossed by several bridges, and is the most conspicuous structure in the city. It contains a splendid banqueting hall, the façade being ornamented by four colossal bronze statues by Thorwaldsen, representing Hercules, Minerva, Nemesis, and Æsculapius. The intention was that the four should symbolize strength, wisdom, justice, and truth; but when the order reached the sculptor at Rome, instead of *Sandhed*, truth, he read it *Sundhed*, health, and so Æsculapius came to be one of the four. There are other famous works by Thorwaldsen, and the palace is also temporarily used for the royal picture gallery. The former palace of Frederiksborg, with a fine park, is used as a military academy. Amalienborg, the principal royal residence, near the Kongens Nytorv, consists of four palaces, erected by different nobles and purchased by the king after the destruction of Christiansborg. One of these is occupied by the king, one by the queen dowager, one by the crown prince, and the last by the foreign office. The former royal palace of Charlottenborg, on the principal square, is occupied by the academy of fine arts. The principal church is that of Our Lady (*Vor Frue Kirke*), in which are several celebrated works of Thorwaldsen, including the original marble statues of the twelve apostles. The original church, built before the 12th century, was destroyed by the great fire of 1728; the second one was destroyed in the bombardment by the English in 1807; the present structure was finished in 1829. Trinity church has a remarkable round tower, originally intended as an observatory, and occupied for that purpose for about 200 years. Our Saviour's church has a beautifully sculptured alabaster font, and a spire with an external staircase terminating under a ball which will contain 12 persons. The so-called marble church was begun in 1746, but the cost of construction so far exceeded the means that the undertaking was abandoned, and it is now a mere ruin. Thorwaldsen's museum was erected by the city (1838–'48) to contain the collection of his works and other objects which he had bequeathed to the public, and also to serve as his mausoleum. The museum of northern antiquities, founded in 1807, and for 50 years (1815–'65) under the charge of one director, Mr. C. Thomsen, was the first in which a systematic effort was made to show the three stages of civilization characterized respectively by the use of stone, bronze, and iron for implements. It is in this respect by far the best in Europe; it is also without a rival in its collection of gold ornaments. The university, founded in 1478, has about 1,200 students, and has become noted for the ability of several of its professors. Connected with it are an observatory, botanical garden, surgical academy, polytechnic institute, and museum of natural history; the library contains 200,000 volumes and 4,000 rare MSS. The royal library ranks among the largest in Europe, having more than 500,000 volumes and 20,000 MSS. The Classen scientific library, deriving its name from two brothers who founded it, has about 30,000 volumes. The ethnographic museum is among the largest and best arranged of its kind. Its object is to illustrate the civilization of non-Scandinavian peoples anterior to the classic period, and its development as compared with that of existing savage tribes. There are many other educational, scientific, literary, and musical institutions. Among the benevolent institutions, besides the hospitals, are the *Varton*, a large red brick building, and four structures containing tenement apartments for workmen of different trades, with infant nurseries, and a large and well arranged institution for the blind. Among the places of amusement are the royal or national theatre on the Kongens Nytorv, which enjoys a considerable subvention from the government; the Tivoli, a kind of public garden, frequented by all classes, where the concerts are very good; and the Alhambra, a similar but smaller establishment. There are several pleasant promenades, the best of which is the Langlinie overlooking the entrance of the harbor. The walk around the ramparts is fine, but those of the citadel are only accessible to the holders of annual tickets. Among the public buildings recently erected are the national bank (1866–'9), the freemasons' lodge (1869–'70), and the palace of the industrial exhibition (1870–'72).—The city is connected by railway with the ports of Elsinore, 20 m. N., and with Korsör, 60 m. S. W. There is regular steamboat communication with foreign ports, and in 1870 nearly 8,000 emigrants sailed from the port for the United States. Street railways and omnibuses traverse the principal thoroughfares. Copenhagen is the centre of the entire commerce of Denmark. Its trade suffered much during the Schleswig-Holstein war, but has since revived. At the beginning of 1872 there were owned here 382 merchant vessels, of which 48 were steamers, with an aggregate tonnage of 49,771. The principal imports are timber, pitch, and tar from Sweden and Norway; flax, hemp,

masts, sail cloth, and cordage from Russia; sugar, chiefly from the West Indies and South America; coffee and tobacco from America; wines and brandy from France; coal, iron, machinery, hardware, tea, and cotton twists from England. The principal exports are corn, rape seed, butter, cheese, beef, pork, horses, cattle, wool, hides, skins, and bones. The principal manufacture is that of porcelain; but the watches and chronometers of Jules Jurgensen are famous, being among the best in the world. The ship building is of considerable importance.—Copenhagen was founded probably in the 11th century. It was originally a fishing village, but as early as the close of the 12th century it became a busy trading town, and owed its first prosperity to the famous bishop Absalon. In 1204 it obtained a city charter, and in 1443 was made the seat of government. During the wars of the Hanse towns it was frequently besieged and suffered heavily. It was several times partly destroyed by fire, and over 22,000 persons died in 1711 from the plague. In 1801 (April 2) the great naval action in which Nelson defeated the Danes was fought near Copenhagen. In 1807 the city was bombarded by the British under Lord Cathcart for three days (Sept. 2–5), when 350 buildings were destroyed entirely, 2,000 more rendered uninhabitable, and 2,000 persons killed. In 1853 the cholera carried off nearly 5,000 persons.

COPERNICUS (Polish, KOPERNIK), **Nikolaus,** a Polish or German astronomer, discoverer of the system of planetary revolutions, born at Thorn, in Prussia, Feb. 19, 1473, a few years after the annexation of the town to Poland, died at Frauenburg, May 24 (according to others, June 11), 1543. After receiving the rudiments of a classical and scientific education in his father's house, he studied medicine and received his doctor's diploma at the university of Cracow, and also devoted himself to mathematics and astronomy, to which he was incited especially by the example of Regiomontanus. He subsequently spent several years in Italy, studying astronomy under Domenico Maria at Bologna, and afterward at Rome, where he gained a reputation rivalling that of Regiomontanus. He taught mathematics at Rome with eminent success, and about 1503 returned to Prussia, having previously been made canon of Frauenburg by his uncle the bishop of Ermeland. Having overcome the opposition which was made to his settlement by the conflicting claims of others, he not only attended faithfully to the duties of his clerical office, but also gave free medical advice to the poor, and at the same time prosecuted astronomical labors. Struck with the complexity of the Ptolemaic system of the universe, he sought to explain the planetary motions upon a more rational principle. After extending his researches over all the then known systems, he came to the following conclusions: The sun and stars are stationary; the moon alone revolves about the earth; the earth is a planet whose orbit is between Venus and Mars; the planets revolve about the sun; and the apparent revolution of the heavens is caused by the rotation of the earth on its axis. His discoveries had attracted the attention of astronomers, who were eager to see the data and proofs, while Copernicus, though he had already finished the composition of a work relating to his theories, hesitated to publish it till the most thorough investigations had satisfied him as to the perfect accuracy of its principles and details. His six books *De Orbium Cœlestium Revolutionibus* were printed at Nuremberg in 1543 (later editions, Basel, 1566, and Amsterdam, 1617 and 1640), under the care of Rheticus, one of his disciples; and the first copy of the work was placed in the hands of Copernicus on the very day of his death. Besides his principal work, he published minor treatises on morals, trigonometry, and coinage. The tower from which he made his observations, and the ruins of a hydraulic machine constructed by him, still exist at Frauenburg. Monuments were raised to his memory at Cracow in 1822, with the appropriate inscription, *Sta, Sol, ne moveare,* and at Thorn in 1853; and a colossal statue by Thorwaldsen at Warsaw in 1829, Poland claiming Copernicus as one of her sons. His life has been written by Gassendi (Paris, 1654), Westphal (Constance, 1822), Czynski (Paris, 1846), and Prowe (1853). In 1872 a prize of 500 thalers was offered for the best biography of him. The 400th anniversary of his birth was celebrated at Posen, Feb. 19, 1873.

COPIAH, a S. W. county of Mississippi, lying W. of Pearl river, which at times is navigable thus far for small boats; former area, 960 sq. m., but in 1870 a portion was taken off to form Lincoln county; pop. in 1870, 20,608, of whom 10,370 were colored. It is watered by bayou Pierre. The New Orleans, Jackson, and Great Northern railroad passes through it. The name in the Indian language means screech owl. The chief productions in 1870 were 408,003 bushels of Indian corn, 17,864 of peas and beans, 55,725 of sweet potatoes, and 15,653 bales of cotton. There were 2,677 horses, 2,049 mules and asses, 4,189 milch cows, 8,492 other cattle, 5,845 sheep, and 20,622 swine; 12 saw mills, 1 tannery, 1 cotton mill, 1 woollen mill, 6 carriage factories, and 1 turning and carving establishment. Capital, Gallatin.

COPIAPÓ, a city of Chili, capital of the province of Atacama, on the right bank of a river of the same name, about 30 m. from its mouth, 425 m. N. of Santiago; pop. about 15,000. It is the centre of the most important mining district of Chili. The town is regularly laid out, with a large plaza, four long streets and about 20 smaller ones crossing at right angles. At the E. end is a suburb occupied by the poorer classes, and the W. end is composed of elegant villas with beautiful gardens. In consequence of the frequency of earthquakes, the houses are of slight construction, being built mostly of wood

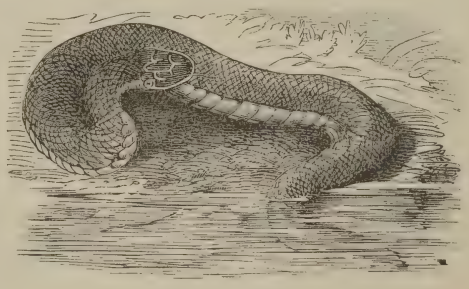
covered with mud and lime. So little rain falls that this is sufficient for protection, and even the principal church is built in this way. The only solid edifice in the city is an old church, the massive walls of which have enabled it to withstand the most violent earthquakes. In the plaza is a bronze statue of Juan Godoy, who discovered the celebrated silver mines of Chañarcillo in 1832. Copiapó has a college and several convents. Among its industrial establishments are a number of works for the reduction of silver ore, iron founderies, and factories for the making of crushing mills and other machinery used in connection with the mines. It has a considerable trade through its port, Caldera, with which it is connected by railway. Its old port, the village of Copiapó, at the mouth of the river, lat. 27° 20′ S., and lon. 71° 2′ W., is now little used.

COPLAND, James, an English physician, born at Deerness, in the Orkney islands, in 1792, died July 12, 1870. He studied medicine at Edinburgh, visited the principal hospitals of Europe, and spent some time in Africa, investigating diseases peculiar to that continent. In 1820, after his return to London, he became a member of the royal college of physicians. From 1822 to 1828 he was editor of the London "Medical Repository," and from 1824 to 1842 a lecturer on pathology and the practice of medicine, first at the Windmill school, and next at the school of the Middlesex hospital. He published "Outlines of Pathology and Practical Medicine," "Elements of Physiology," and a "Dictionary of Practical Medicine," in four volumes, which was reprinted in the United States and translated into German. In 1850 he published an essay on palsy and apoplexy.

COPLESTON, Edward, D. D., an English bishop, born at Offwell, Devonshire, Feb. 2, 1776, died near Chepstow, Oct. 14, 1849. He was educated at Oxford, in 1802 was appointed professor of poetry there, and in 1813 published his lectures under the title of *Prælectiones Academicæ*. In 1814 he became provost of Oriel college, in 1826 dean of Chester, and in 1827 bishop of Llandaff and dean of St. Paul's, London. He contributed to the "Quarterly Review," and wrote an "Inquiry into the Doctrines of Necessity and Predestination" (1821).

COPLEY, John Singleton, an American painter, born in Boston, July 3, 1737, died in London in September, 1815. Without the aid of instructors, and before seeing any tolerable picture, he painted pieces which were highly admired. In his 17th year he adopted painting as a profession, and in 1760 he sent to the royal academy a picture of a "Boy and Tame Squirrel," the coloring of which was deemed exquisite. He obtained a considerable income as a portrait painter, till in 1774 he visited Italy, where he studied especially the works of Titian and Correggio. In 1775 he established himself in London, and in 1783 was chosen a member of the royal academy. The most celebrated of his works is the "Death of Lord Chatham," now in the national gallery, representing the orator falling after his speech in opposition to the American war, and containing also portraits of the most distinguished peers. It was engraved by Bartolozzi on a plate of 30 inches by 22, and impressions were sent by the painter to Washington and John Adams. In 1790 he was commissioned to paint the large picture, now in the council chamber of the Guildhall, of the "Siege and Relief of Gibraltar." Some of his most esteemed paintings are portraits of several members of the royal family, "Major Pierson's Death on the Isle of Jersey," "Charles I. demanding the five Impeached Members in the House of Commons," and the "Surrender of Admiral de Winter to Lord Duncan." They are remarkable for correctness of drawing and brilliancy of coloring. His best works were collected by his son Lord Lyndhurst, and many of them have been engraved. A sketch of his life and works, by A. T. Perkins, was published in Boston in 1873.

COPPER (Lat. *cuprum*, from Cyprus the island, in which the ores of this metal were mined by the ancient Greeks), one of the first metals known to man. Tubal Cain, the seventh in descent from Adam, we are told, was "an instructor of every artificer in brass and in iron." In the book of Job we read that "copper is molten out of the stone." Cheops, an Egyptian king of the fourth dynasty, it is recorded, worked a copper mine in the peninsula of Sinai. The ancient Egyptians employed an alloy of it for working hard stones, and Wilkinson suggests that they may have had the art of hardening it. The Syrians and Phœnicians, as also the Greeks and Romans, consumed the metal largely in the manufacture of monuments and statues of bronze. The single colossus of Rhodes, after having lain in fragments for nine centuries, is said to have required 900 camels to convey its pieces away. The ores seem, therefore, not only to have been worked extensively by the ancients, but the skill and facilities for producing large castings appear to have been quite equal to those possessed by the moderns. Besides its use as an alloy in the manufacture of bronze, it was also employed in coin in the pure state. The metal itself was probably first discovered, as it is now found, in a native state, and by the melting of this the nature of the rich ores associated with it came to be known. The obscure races that inhabited this continent prior to the Indians possessed an acquaintance with it, as appears from the various small utensils of copper found in the ancient mounds of the western country; and the extensive mining works, probably of the same people, at Lake Superior (see Copper Mines), testify to the knowledge of it possessed by some ancient race of greater skill than the Indians. The Aztecs of Mexico made use of chisels and axes of copper, some of which are found with the large half-finished blocks of granite in the quarries of Mitla; and these



naturally suggest the possibility of these people having had the art of giving to the metal hardness adapted to its use for quarry tools. Prescott points out other resemblances in their works to those of the Egyptians. The Peruvians, too, used copper for the same purposes; and Humboldt gives the composition of a chisel found in a silver mine opened by the incas near Cuzco, viz., 94 per cent. copper and 6 per cent. tin. This is almost identical with the composition of the chisel found by Wilkinson at Thebes, which was 94 per cent. copper, 5·9 per cent. tin, and 0·1 per cent. iron. The Scandinavian tumuli, in Denmark, have afforded similar collections of copper utensils of very remote antiquity, many of which are preserved in the museum of Copenhagen; among them are knives, daggers, chisels, hammers, wedges, axes, &c. There are swords and knives with blades of gold and cutting edges of iron; some are of copper, also similarly faced, the iron appearing to be the rare and choice metal. In the work of J. Arthur Phillips and John Darlington, "Records of Mining and Metallurgy," are given many analyses made by Mr. Phillips of coins and sword blades, some of the former dating back as far as 500 B. C. In the most ancient coins the alloy is, copper 62 to 72 per cent., tin about 7, and lead from 19½ to 29·32 per cent. Tin is almost invariably present. Zinc first appears in specimens about the commencement of the Christian era. The cutting instruments are uniformly composed of copper and tin, generally about one part of the latter in ten, and sometimes lead forms a small part of the alloy. During the middle ages there is little recorded concerning the working of copper mines and the use of the metal. Copper has been obtained in recent times from the mine of Rammelsberg, near Goslar, in the Hartz mountains, which was worked in the 10th century. The Swedish mine of Fahlun competed with the above in the production of copper in the 12th century; and in the next century the mines of Thuringia were worked. In Great Britain, the Parys mine in Anglesea, it is believed, was worked by the Romans. This was very productive in the latter part of the 18th century, causing by the abundance of its ores the price of the metal to be considerably reduced. In 1799, when it was nearly exhausted, the price of copper rose again to £128 per ton. The rich veins at Newlands near Keswick were worked in 1250; and in 1470, as appears by a charter granted by Edward IV., the business was extensively carried on. The metal was obtained at Ecton hill in Staffordshire previous to its discovery in Cornwall. The mines of Cornwall, worked for tin at very early periods, appear to have been little regarded for the copper ores they contained before the middle of the 18th century.—Copper is a metal remarkable for its fine red color bordering upon yellow, and for its peculiar and disagreeable taste and smell when rubbed. Obtained in very thin films on the surface of glass, by precipitation from its solution in ammonia by the aid of a ferrous salt, it is transparent, and by the light transmitted through it appears green, but by reflected light red. Its specific gravity is from 8·8 to 8·96, varying according to the method of its manufacture. Its hardness is from 2·5 to 3, being about the same as that of gold and silver. It is so ductile that it is hammered into very thin sheets and drawn out into fine wire. In tenacity it ranks next to iron, a wire $\frac{1}{13}$ inch in diameter sustaining a weight of 300 lbs. Its power of conducting heat is 2½ times that of iron. It expands, when heated from 32° to 212° F., $\frac{1}{518}$ of its length. It is a ready conductor of heat, and one of the best conductors of electricity. It melts at a full red heat, estimated at from 2,200° to 2,500° F., and at a white heat the vapors passing from it burn with a green flame. The equivalent weight of copper is 31·7, and its symbol is Cu. It crystallizes in forms of the isometric or tesseral system. Copper undergoes no change in dry air, but when exposed to moist air it becomes slowly covered with a greenish coating, which is a hydrous carbonated oxide of the metal. When heated to redness in contact with the air, it becomes covered with a reddish scale, which is a peculiar oxide, to be noticed further on. Copper is readily attacked and dissolved by nitric acid, with the evolution of nitric oxide gas, and the formation of a blue solution of nitrate of copper. Hydrochloric acid does not attack the metal unless the air has access, when it dissolves, forming a chloride. Dilute sulphuric acid has no action on copper, but it decomposes the concentrated acid with the aid of heat, with the evolution of sulphurous acid and the production of sulphate of copper.—Copper forms two principal compounds with oxygen, the black or cupric oxide, often called protoxide, CuO, and the red or cuprous oxide, called also suboxide or dinoxide, Cu_2O. Both of these are found in nature constituting ores of copper, and may also be obtained artificially. The protoxide dissolves readily in acids, giving rise to salts white and blue or green in color; and the oxide itself, though black when anhydrous, is blue when combined with water. The red or suboxide, which is ruby or vermilion red in color, yields a yellow hydrate, which readily absorbs oxygen from the air and passes to the state of protoxide. By most acids it is converted into a salt of the protoxide with the separation of one half its copper in the metallic state, but by the action of hydrochloric acid is changed into a white subchloride or dichloride, Cu_2Cl, which is insoluble in water, though soluble in strong solutions of common salt and other chlorides. The black oxide, on the contrary, yields with hydrochloric acid a very soluble protochloride, CuCl, which is green in solution, but brown when deprived of water. —Certain salts of copper are of use in the arts, and may here be briefly noticed. Sulphate of

copper, or blue vitriol, is best prepared by dissolving the oxide in dilute sulphuric acid, or by oxidizing at a low red heat the native compounds of sulphur and copper, as is done in the roasting of copper ores, which after this process give to water a solution of sulphate. This salt crystallizes in large blue prismatic crystals, which have the composition $CuO, SO_3 + {}_5HO$, and contain almost exactly one fourth their weight of metallic copper. Besides its use in medicine, noticed hereafter, considerable quantities of sulphate of copper are consumed as an application to seed wheat to destroy the germs of the fungus known as smut. For this purpose the grain is soaked in a solution of the salt. It is also largely consumed in dyeing, and in the preparation of various pigments, among which are Scheele's green and Schweinfurt green, both very beautiful but poisonous colors, in which oxide of copper is combined with arsenic; Brunswick green, which is an oxychloride of copper; and verditer, a carbonate of copper. Verdigris is the name given to various acetates of copper. A pure crystallized acetate is prepared by dissolving oxide of copper in acetic acid; but the pigment known under that name is a mixture of several basic acetates or compounds of acetate and hydrous oxide of copper, prepared by parting sheets of copper in layers with the refuse of the grape from which the juice has been expressed, when a greenish layer of verdigris forms, and after some weeks is scraped off.—The sources of copper are the native metal and the oxidized and the sulphuretted ores. Mention will be made of the latter in treating of copper mines. The ores in which the metal occurs in an oxidized form are as follows: red oxide, or ruby copper, which is the suboxide already noticed, and occurs both massive and crystallized in isometric forms; in its pure state it consists of 88·8 parts of copper and 11·2 of oxygen. The black oxide is less abundant in nature, and generally occurs in an earthy uncrystalline form, but in 1846 a vein of massive and crystalline black oxide was found at Copper Harbor, Lake Superior, which yielded about 20 tons of the ore. The native carbonates of copper are two in number. The one is called azurite, and occurs in beautiful transparent blue crystals in certain copper mines, but is rarely abundant. The other, known as malachite, is sometimes crystallized, but more often occurs in concretionary masses of various shades of green, which are generally banded or arranged in such a manner that the mineral, which takes a fine polish, is much prized as an ornamental stone. Great quantities of it are found in the Siberian mines, and many beautiful objects are manufactured from it. Both of these carbonates contain water and an excess of oxide, constituting what are called basic carbonates. Malachite, from the large quantities in which it is sometimes found, is a valuable ore of copper. Chrysocolla is the name given to a green hydrated silicate of copper which sometimes accompanies the other oxidized ores of this metal, while atacamite is a green oxychloride of copper which occurs in considerable quantities in some South American mines. The white dichloride of copper has also been met with in a Chilian copper mine. All of these ores probably result from the oxidation of the native metal, or of the sulphuretted compounds of copper from which by far the greater part of the supplies of this metal are derived. Sulphur combines with copper in two proportions, corresponding to the two oxides already noticed. The protosulphide, CuS, is known as indigo copper, and is comparatively rare; but the disulphide, called also copper glance or vitreous copper ore, is more abundant, and constitutes a very rich ore. It is soft, leaden gray in color, and contains about 80 per cent. of copper. These ores are, however, less frequent than the double sulphides of copper and iron, one of which is known by the names of bornite, erubescite, variegated copper ore, purple, peacock, or horse-flesh ore, epithets suggested by the various shades of color which it presents upon its fresh or partially tarnished surfaces. Its composition varies slightly, the analyses of different varieties yielding from 56 to 63 per cent. of copper, 21 to 28 of sulphur, and 7 to 14 of iron. A less common ore is the so-called tetrahedrite, fahlerz, or gray copper, which is a complex sulphide, containing, besides copper, portions of arsenic or antimony, and more or less zinc and iron, often with silver or mercury. The most abundant ore of copper is the so-called yellow copper ore, pyritous copper, copper pyrites, or chalcopyrite, which is of a brass-yellow color, brittle, and, like the other sulphuretted copper ores, so soft as to be cut by a knife. It contains in its purest form 34·6 per cent. of copper, 34·9 of sulphur, and 30·5 of iron, but very generally occurs mechanically intermixed with more or less iron pyrites. Arsenides of copper are met with in nature, but have no importance as ores of the metal.—The uses of copper in the arts are very various, from its toughness, malleability, ductility, and resistance to oxidation; and moreover, from its great power of conducting both heat and electricity, it is adapted to very many useful purposes. Among these are the construction of boilers and vessels for distilling, and various chemical and culinary purposes; for submerged electric cables; for coinage; and for the engraver's art. In the construction of ships it is largely used for sheathing; and from the poisonous quality of the products of its slow oxidation in sea water it prevents the adhesion of barnacles and other shell fish, which would otherwise fix themselves upon the surface of the vessel and greatly impede its movements. Unlike iron, the results of its oxidation do not exert a corrosive and destroying action on wood, and for this reason copper replaces iron for the construction of the nails, bolts, and fastenings of ships. For many of these and other purposes, it is found

advantageous or economical to alloy copper with other metals. Thus, with zinc it forms brass; with tin, bronze and bell metal; and with zinc and nickel, German silver. An alloy of copper with from 5 to 10 per cent. of aluminum is known by the name of aluminum bronze, and from its golden yellow color, its great hardness and elasticity, and its resistance to oxidation, is susceptible of very many applications both useful and ornamental in the arts. It has lately been found that the union with copper of small portions of phosphorus imparts to this metal great hardness and great strength, so that it has been proposed to use the new phosphorus bronze, as it is called, for the manufacture of large guns. Small quantities of copper are alloyed with gold and with silver to harden these metals, both for the purposes of coinage and for various articles of manufacture.—A minute portion of copper has been found in the human body, and is considered a normal constituent. Sulphate of copper (but not copper itself) is used in medicine as an emetic in the dose of about two grains, acting rapidly and safely. In smaller doses it is an astringent. Externally it is applied to chronic granulating surfaces as an astringent and stimulant. In appropriate cases it is better than the nitrate of silver. When poisoning has taken place from this or other soluble salts of copper, the symptoms are chiefly those of gastro-intestinal irritation. Under these circumstances, milk and eggs should be administered, by which less soluble combinations of the metal are formed with the caseine and albumen they contain. The best antidote is ferrocyanide of potassium, which forms with the poison an insoluble ferrocyanide of copper. The existence of a form of chronic poisoning due to the gradual absorption of copper compounds, and analogous to lead poisoning, has not been satisfactorily established. — See Copper Mines, and Copper Smelting.

COPPERAS (Fr. *couperose*), a metallic salt, known also as green vitriol. It is a hydrous ferrous sulphate or protosulphate of iron, and is represented by the formula $Fe,SO_4,7HO$. It forms pale green transparent prismatic crystals, which are very soluble in water. When exposed to a gentle heat they lose their water of crystallization and are converted into a whitish pulverulent mass. Copperas slowly absorbs oxygen from the air, with the formation of a basic sulphate of peroxide of iron, of a rusty reddish yellow color; this change takes place more rapidly when it is dissolved in water. Copperas has a peculiar metallic styptic taste, which belongs to the other protosalts of iron. It is largely used in the arts for dyeing black, and in the manufacture of ordinary black writing ink. It is also employed in photography as a reducing agent, and in many other chemical processes. Pure copperas may be obtained by dissolving metallic iron in dilute sulphuric acid; hydrogen gas is evolved, and a green solution is obtained, from which crystals are got by concentration and cooling. In this way considerable quantities of copperas are manufactured from the refuse sulphuric acid which has been employed in the refining of petroleum. The chief supply of copperas is however obtained from the oxidation of the native sulphides of iron, some of which spontaneously absorb oxygen from moist air, and become covered with an efflorescence of copperas. In the case of other varieties of pyrites, which are less readily oxidable, they are first subjected to a partial calcination, by which a part of the combined sulphur is expelled, and then piled up in heaps, which are frequently moistened and lixiviated with water from time to time. The solutions thus obtained are concentrated by evaporation over a fire in lead or iron tanks, and then led into crystallizing vats, where the copperas separates on cooling in large masses of fine green crystals. The process of oxidizing a large quantity of pyrites is very slow, and requires many months or even years for its completion. Large quantities of copperas are manufactured by this method at Stratford in Vermont.

COPPERHEAD (*trigonocephalus contortrix*, Linn.; genus *agkistrodon*, Bd. and Gd.), a North American venomous serpent, the most dangerous after the rattlesnake. The head is thick and triangular; it has a pit between the eye and the nostril; the upper jaw furnished with poisonous fangs; the eyes large, and the orbital plates projecting; the iris is bright golden with a reddish tinge. The neck is contracted, and its scales are smooth; the body long, thick to near the tail, and covered above with rhomboidal carinated scales, except the lower rows, which are smoother; the last abdominal plate is very large; there are no rattles, the tail being short and conical, ending in a horny tip. The general color above is a light nut-brown, with transverse bars of dark brown, narrowest in the middle, broad and bifurcated on the sides; the under parts are flesh-colored, freckled with minute dark brown spots; near the flanks are rounded dark blotches, corresponding to the bifurcations of the dorsal bars. In a specimen 26 inches long, the head measured a little more than an inch in length by 11 lines in width; length of body 21 inches,

Copperhead.

and of tail 3½ inches; greatest circumference 3¾ inches; the abdominal plates were 150, and the subcaudal 42, with 4 pairs of bifid scales near the apex. It prefers dark and moist places, and feeds upon lizards, frogs, mice, and small birds. It is more dreaded than the rattlesnake, as it gives no warning of its proximity; it never attacks man except in its own defence; as with other venomous snakes, a very slight blow is sufficient to kill it. From its thick body and short tail, it is slow and clumsy in its motions, and it cannot ascend trees. It is also called "chunkhead" and "deaf adder." According to Dr. Holbrook, it is found from western New England to Florida, and from the Atlantic to the borders of the Alleghanies.

COPPERMINE RIVER, in British America, rises in Lake Providence, about lat. 65° N., lon. 112° W., flows a little W. of N. to just beyond the Arctic circle, when it bends abruptly W., after which its course is a little E. of N. to its mouth in the Duke of York's archipelago, an inlet of the Arctic ocean, at lat. 67° 40′ N., lon. 115° 37′ W. It flows through a very uneven region, and forms several lakes and many rapids and cataracts, but is navigable by canoes and boats. Its length is about 300 m. Fur-bearing animals, such as the bear, the fox, and the ermine, abound along its banks. The river derives its name from a copper mine discovered near its mouth. The region through which the Coppermine flows was first explored in 1821 by Sir John Franklin. Its mouth was the first point on the Arctic coast of America visited by Europeans.

COPPER MINES. Copper occurs in nature both in the metallic state, when it is known as native copper, and mineralized or combined with oxygen, sulphur, and various other foreign substances, constituting what are called the ores of copper. (See Copper.) This metal and its ores occur, like most other metals, both disseminated in beds of various kinds of rock, and in veins or lodes, which are deposits in fissures intersecting previously formed rocks. Copper and copper ores are found in rocks of very various geological ages. The crystalline schists of the eozoic age contain in many places both interstratified ore beds and lodes carrying the ores of this metal. This is true of the rocks of the great Appalachian system, which abound in deposits of copper ores in various localities, from Newfoundland through Quebec and Vermont into Virginia, the Carolinas, Tennessee, and Georgia. The copper ores of the Rocky mountains and those of Cuba and Chili are also in crystalline rocks; and the same is true of those of the Ural, of Norway, Sweden, Cornwall, and Devonshire. The great deposits of native copper found on the shores of Lake Superior, however, belong to a series of sandstones and conglomerates, interstratified with contemporaneous bedded trappean rocks, which rest upon the crystalline Huronian schists, and, being overlaid by the upper Cambrian rocks of the New York system, may be regarded as of the lower Cambrian age. Rich ores of copper occur in the palæozoic series in the so-called Shawangunk grit of Ulster co., New York. In Connecticut, New Jersey, and Pennsylvania, deposits of copper ores are found in sandstones of the mesozoic age, and somewhat similar deposits occur in various parts of Europe. The well known mines of Mansfeld in Germany, in which a sulphuretted ore is finely disseminated through black bituminous schists, are examples. There are important mines in Siberia and the Ural mountains. The product of Russia is estimated at 4,660 tons a year. The Swedish copper mine of Fahlun, in Dalecarlia, is supposed to have been worked for nearly 1,000 years. It was long extremely productive, yielding in the beginning of the 17th century nearly 4,000 tons annually, but it has since greatly declined. There are mines in other parts of Sweden, where in 1855 there were 15 smelting works, producing 1,990 metric tons (2,205 lbs.) of pig copper; in 1863, 16 works, producing 2,222½ tons; in 1868, 12, producing 2,410 tons. The product for 1869 was 2,600 tons; for 1870, 2,193 tons. The exports of crude copper in 1867 amounted to 1,928 tons; in 1868, 2,320; in 1869, 2,076; and in 1870, 1,957. From Norway there were imported into Great Britain, in 1867, 6,007 tons of ore, worth £34,209, and 193 of unwrought or partly wrought copper; in 1868, 6,871 tons of ore, worth £66,995, and 216 of copper; in 1869, 6,589 of ore, worth £154,508, and 105 of copper; in 1870, 1,911 of ore, worth £9,110, and 100 of copper; in 1871, 4,299 tons of ore, worth £26,520, and 97 of copper.—In the German empire copper is mined at Holzappel and elsewhere in Nassau; in the Eifel mountains, and at Eschweiler and Stolberg, near Aix-la-Chapelle; in Westphalia, and in the Hartz mountains, as well as at Mansfeld, in Prussian Saxony. In 1869, 217,415 metric tons of ore were obtained in the Zollverein, valued at about $1,300,000; in 1870, 207,381 tons, worth $1,250,000. The product of the smelting works in 1869 was 5,129 tons of copper, valued at over $2,000,000, and 4,730 tons of brass of about the same value; in 1870, 4,797 tons of copper, worth about $1,800,000, and 4,411 of brass, of about the same value. The value of sulphate of copper in 1869 was about $270,000, and in 1870 about $285,000. In 1869 the imports of copper and manufactures of the same amounted to 12,240 tons; the exports were 7,413 tons. In Prussia alone 156 copper mines were in operation in 1869, employing 6,691 miners, and producing 214,507 tons of ore, valued at about $1,275,000; 13 smelting works, employing 1,408 hands, and producing 4,448 tons of crude copper, worth about $1,750,000; 23 establishments, with 658 hands, producing 3,713 tons of copper manufactures, valued at $1,775,000; 77 establishments, with 1,381 hands, producing 4,722 tons of brass, worth about $2,025,000; and 2 manufactories

of sulphate of copper, employing 47 hands, and producing 945 tons, valued at $110,000. The most important mines of the Austrian empire are in Hungary, though the metal is also found in Bohemia. The product of ore, metal, and sulphate, with the value of each, from 1863 to 1867, is shown in the following table:

Years.	Ore, tons.	Value.	Copper, tons.	Value.	Sulphate, lbs.	Value.
1863..	58,037	$751,605	2,336	$1,326,861	409,173	$29,053
1864..	66,255	940,682	2,542	1,411,658	323,084	23,545
1865..	44,763	780,222	2,380	1,209,485	390,544	30,573
1866..	50,825	761,937	2,387	1,180,398	508,931	40,522
1867..	53,266	781,864	2,601	1,301,286	1,024,698	60,165

The product of copper for 1869 was 2,698 metric tons.—In Italy copper is found in the mountains bordering the gulf of Genoa, and in Sardinia, and there are mines in the mountains of Modena, and in central and southern Tuscany. In 1865 there were 34 mines in Italy, employing 2,412 hands, and producing 16,075 metric tons of ore, valued at $318,725; and 21 smelting works, with 287 hands, producing 1,032½ tons of copper, worth $552,915. The average production during the period 1867–'70 was 25,500 tons of ore and 550 tons of pig copper.—In France there are copper mines at Chessy and St. Bel near Lyons, but the product is not large. Considerable quantities of ore and crude metal, however, are imported, and smelted in that country. The product of the mines and smelting works for different periods has been as follows:

YEARS.	MINES.		SMELTING WORKS.	
	Copper, tons.	Value.	Copper, tons.	Value.
1855	99	$64,400	7,190	$4,359,400
1861	465	255,400	11,410	5,406,400
1867	755	339,429	20,016	9,301,454
1868	811	340,238	22,422	10,160,900

The imports into France from 1857 to 1868 are shown by the following table:

YEARS.	ORE.		CRUDE COPPER.	
	Tons.	Value.	Tons.	Value.
1857	4,861	$972,173	12,345	$8,024,568
1858	4,347	869,462	11,199	6,383,605
1859	6,582	1,316,439	12,770	6,640,545
1860	4,135	827,006	13,350	7,209,162
1861	5,827	1,165,400	13,959	6,700,489
1862	8,862	1,772,492	13,301	6,384,313
1863	8,976	1,795,292	16,175	7,440,736
1864	7,950	1,589,928	17,827	8,735,173
1865	6,392	1,278,461	15,610	7,492,963
1866	4,217	843,423	20,576	9,341,631
1867	3,806	721,192	18,900	7,370,956
1868	5,742	1,091,074	19,310	6,951,605

Of the 71,697 tons of ore imported into France during that period, 22,119 were from Peru and 7,870 from Algeria. The value of manufactured, alloyed, and old copper imported in 1868 was $1,348,014. The exports in 1867 were 3,454 metric tons of ore and 2,647 of crude copper; in 1868, 2,976 tons of ore, 3,812 of crude copper, and $1,380,861 worth of manufactured copper.—Spain is one of the chief copper-producing countries, and its mines have long been famous. The most important are those of Huelva, near the Rio Tinto, in Andalusia. The quantity of ore raised has been as follows: in 1864, 294,079 metric tons; in 1866, 347,257; in 1868, 284,184. The amount worked at the government mine of Tinto in 1864 was 64,756 tons, producing 1,046½ tons of copper; in 1866, 67,608 tons, producing 1,135 tons of copper; in 1868, 56,453 tons, producing 1,124 tons of copper. The average fineness was 1¾ per cent. At the same rate the total copper product of the kingdom for 1864 would be 5,146 tons; in 1866, 6,077 tons; in 1868, 4,973 tons. From Portugal were exported to Great Britain, in 1868, 1,774 tons of ore, worth $125,830; in 1869, 4,214 tons, worth $308,840; in 1870, 2,592 tons, worth $152,275; in 1871, 2,895 tons, worth $287,755.—In England, the mines of Cornwall and Devonshire were formerly the most productive known, but they have greatly declined. There are also some mines in Cumberland, Wales, and Ireland. In 1757 the mine called Huel Virgin, in Cornwall (now a part of the consolidated mines), produced in two weeks, at a cost of £100, copper ores which sold for £5,700; and in the next 23 days the product, obtained at about the same proportional cost, sold for £9,600. From 1744 to 1758 the average annual value of the copper product of Cornwall is stated at from £100,000 to £160,000. The production continued rapidly to increase, until in 1800 it amounted to 55,981 tons of ore, which produced 5,187 tons of metal, worth £550,925. In 1805, 78,452 tons of ore produced 6,234 tons of copper, worth £862,510; and though in subsequent years larger quantities of equally rich ore were produced, the same value was not reached till 1834, when 143,296 tons of ore produced 11,224 tons of copper, worth £887,502. The product of the mines of the United Kingdom since 1847 has been as follows:

YEARS.	Copper, tons.	Value.	YEARS.	Copper, tons.	Value.
1847...	14,139	£996,199	1860...	15,968	£1,706,261
1848...	13,608	795,582	1861...	15,381	1,572,480
1849...	12,670	836,552	1862...	14,843	1,493,241
1850...	13,314	954,949	1863...	14,247	1,409,608
1851...	12,914	866,080	1864...	13,302	1,350,699
1852...	12,868	1,076,883	1865...	11,888	1,134,664
1853...	13,137	1,281,410	1866...	11,153	1,019,168
1854...	13,113	1,322,903	1867...	10,233	831,761
1855...	13,854	1,400,657	1868...	9,817	761,602
1856...	13,275	1,283,639	1869...	8,291	644,065
1857...	17,375	2,154,500	1870...	7,175	551,309
1858...	14,456	1,562,693	1871...	6,280	471,000
1859...	15,770	1,734,700	1872...	6,000	450,000

The product for 1856 includes that of Cornwall and Devon only; that for 1872 is estimated. In addition to the above, considerable quantities of copper are obtained from pyrites mined in the kingdom. The amount for 1867 was 2,338 tons; 1868, 1,530; 1869, 1,519; 1870 and 1871,

about 1,500 tons each. The separate product of Wales in 1866 was about 650 tons; of Ireland, 1,335 tons. The number of mines in the United Kingdom in 1862 was 228; 1863, 222; 1864, 201; 1865, 203; 1866, 173. The average yield of the ore is 7 or 8 per cent. The following tables exhibit the British trade in copper from 1857 to 1871:

YEARS.	Imports.				Exports (foreign and colonial products).	
	Ore and regulus.	Value.	Copper, all kinds.	Value.	Copper, all kinds.	Value.
	Tons.		Tons.		Tons.	
1858	97,099	£2,138,880	7,366	£734,779	2,317	£234,149
1859	84,455	1,812,023	11,829	1,218,781	2,409	251,701
1860	97,317	2,011,558	12,649	1,221,302	3,682	355,706
1861	94,480	2,008,226	16,224½	1,448,899	3,923	356,705
1862	117,438	2,631,056	13,644	1,223,543	8,679	786,912
1863	102,099	2,000,473	12,698	1,140,861	6,289	574,380
1864	93,304	2,054,674	25,388	2,314,444	9,023	854,168
1865	122,248	£269,864	22,144	£1,978,576	9,347	£852,714
1866	129,547	2,440,754	21,409	1,687,567	14,092	1,133,284
1867	102,782	1,801,155	30,013	2,201,584	14,160	1,050,675
1868	114,036	2,069,873	35,535	2,550,712	20,851	1,498,425
1869	110,968	1,999,285	31,885	2,229,513	12,140	849,904
1870	106,632	2,015,128	29,964	2,019,544	14,519	972,158
1871	78,691	1,777,551	32,542	2,157,425	17,253	1,181,328

The relative amounts of ore and regulus imported have been as follows: 1868, 83,334 tons of ore and 30,702 of regulus; 1869, 72,199 and 38,769; 1870, 62,104 and 44,528; 1871, 48,215 and 30,476. Nearly all the regulus and the greater part of the unwrought copper are brought from Chili, while the ore is furnished by various copper-producing countries.

EXPORTS (DOMESTIC PRODUCE).

YEARS.	Unwrought copper, tons.	Value.	Mixed or yellow metal, tons.	Value.	Other sorts of wrought copper, tons.	Value.	Brass, tons.	Value.
1857	7,146	£852,055	6,327	£712,643	10,670	£1,415,398	1,098	£143,953

The exports are to every quarter of the globe, but perhaps India is the most important market.—The most important copper mines in the United States are those on the south shore of Lake Superior, where the metal occurs in the bedded trappean rocks, with interstratified sandstones and conglomerates, which are developed to a greater or less extent in various localities along both sides of the lake, and are everywhere copper-bearing. The copper is almost wholly in the native or metallic state, and occurs in veins cutting the strata, associated with quartz and various spars and crystalline minerals; and also disseminated in the beds of rock, in which the richest and most productive mines of all are now wrought. While in some of the veins masses of pure copper weighing many tons are met with, the copper in the beds is generally in smaller masses or grains. In this state it occurs in the layers of soft amygdaloidal trap, locally known as ash beds; while in other cases the pure metal appears as the cementing material of conglomerates or breccias made up of the ruins of red feldspar porphyry rocks belonging to an older formation. Remarkable examples of this latter mode of occurrence are seen in the Boston and Albany mine and the Calumet and Hecla mine, the latter of which yielded in 1872 the enormous amount of 8,000 tons of fine copper, or about one tenth of the entire product of the globe. The working of these mines of Lake Superior commenced in 1845, and from that period up to 1858 the entire production of the whole region amounted to a little over 16,000 tons. The copper is extracted by crushing and washing the rock, and is then in a nearly pure state, requiring only to be melted down to ingot copper. There are evidences that mines were worked in this region ages since by a primitive people who had only stone tools for their work. A copper region of great importance occurs in adjacent parts of the states of Virginia, North Carolina, Tennessee, and Georgia, where sulphuretted ores are found in crystalline schists. For several years previous to 1861 the numerous mines in these regions were wrought in an imperfect manner; but the civil war, together with the great depression in the price of copper which followed up to 1871, has caused these mines to be for the most part abandoned, with the exception of those of Ducktown, Tennessee, which yield large quantities of ores that are smelted on the spot. With the

present augmented price of copper, and with the aid of improved processes for extraction of the metal from its ores, this region may become a second Cornwall. The deposits of copper ore in the mesozoic sandstones of Connecticut and New Jersey were formerly worked to a considerable extent. From those of Belleville, in the latter state, large quantities of ore were shipped to England as early as 1731. From the irregularity of these deposits, and from the fact that part of the metal is disseminated through the sandstones in an oxidized condition, and not easily extracted by the ordinary smelting processes, these mines have been abandoned. Very lately, however, rich deposits of valuable copper ore have been opened in these sandstones in Chester co., Pa. According to the census of 1870, there were in the United States 40 copper-mining establishments, with 93 steam engines of 6,318 horse power, 3 water wheels of 70 horse power, and 5,404 hands, of whom 2,157 were employed above ground, and 3,247 under ground; capital invested, $7,789,374; wages paid, $2,706,264; value of materials, $586,844; value of product, $5,201,312. The mines were distributed as follows:

STATES.	Number.	Steam engines.	Horse power.	Hands.	Capital.	Value of product.
Arizona	2	....	....	25	$2,500	$7,000
Maryland	2	2	85	72	157,000	71,500
Michigan	27	86	5,943	4,188	5,866,374	4,312,167
Nevada	1	....	....	20	3,000	30,000
North Carolina	1	1	80	105	80,000	96,000
Pennsylvania	2	....	....	7	30,500	7,800
Tennessee	2	*2	120	620	550,000	310,000
Vermont	2	1	50	355	1,000,000	358,845
Virginia	1	1	40	12	100,000	8,000

The more important of the Maryland mines is in Frederick co.; the other is in Carroll co. The Nevada mine is in Humboldt co., the North Carolina mine in Chatham co., the Tennessee mines in Polk co., and the Vermont mines in Orange co. Of the Michigan mines, 11 are in Houghton co., product $3,231,888; 6 in Keweenaw co., product $823,477; and 10 in Ontonagon co., product $256,802. The following table exhibits the product of the Lake Superior mines since 1858, in tons of 2,000 lbs.:

YEARS.	Copper.	YEARS.	Copper.	YEARS.	Copper.
1858	4,100	1863	6,500	1868	9,987½
1859	4,200	1864	6,500	1869	12,250
1860	6,000	1865	7,000	1870	12,950
1861	7,500	1866	7,000	1871	12,850
1862	6,300	1867	8,250	1872	12,125

The product of Vermont for 1872 was between 400 and 500 tons; of Tennessee, about 750; and of the United States, nearly 14,000. The imports of copper ore for the year ending June 30, 1872, amounted to 1,355½ tons (2,240 lbs.) valued at $85,622; of unmanufactured copper, 2,280 tons, worth $1,040,458; the manufactures of copper imported were valued at $800,478. Of the ore, 1,091 tons were from Chili, and 248½ from Canada; of the copper, 1,671 tons came from England, 290 from Cuba, 123 from the British West Indies, and 115 from Chili. The exports of domestic ore were 1,778 tons, worth $101,752; of domestic copper, 120 tons, worth $64,844; the value of domestic manufactures of copper exported was $121,139. The exports of foreign copper and ore were valued at $7,406. The imports of brass and brass manufactures were valued at $173,515; domestic exports, $229,458; foreign exports, $1,966. The production of Canada and Newfoundland may be seen from the imports of ore and regulus into Great Britain from those colonies. The imports from the Dominion of Canada in 1867 were 1,062 tons, worth $51,155; in 1868, 5,270 tons, worth $277,435; in 1869, 3,152 tons, worth $97,335; in 1870, 2,907 tons, worth $191,830; in 1871, 2,083 tons, worth $153,670. From Newfoundland were imported in 1867, 4,120 tons, worth $189,849; in 1868, 8,061 tons, worth $254,325; in 1869, 6,237 tons, worth $159,220; in 1870, 4,162 tons, worth $259,570; in 1871, 1,887 tons, worth $91,375.—There are important copper mines near Santiago in Cuba, from which about 25,000 tons of ore, averaging 16 per cent. of metal, were shipped to England in 1850. The shipments of ore and regulus in 1867 were 7,257 tons, worth $477,150; in 1868, 10,861 tons, worth $744,445; in 1869, 3,869 tons, worth $298,645. The working of the mines was interrupted by the insurrection, and in 1870 and 1871 the shipments amounted to only a few hundred tons.—Chili is the chief copper-producing country of the world. In 1853 the total copper product was 55,700 tons, of which Chili yielded 14,000 tons, or 25 per cent.; while at present that country produces about one half of all the copper mined on the globe. The exports of copper from Chili for a series of years have been:

YEARS.	Tons.	YEARS.	Tons.	YEARS.	Tons.
1862	43,109	1866	44,820	1870	49,139
1863	32,540	1867	44,654	1871	41,200
1864	47,500	1868	43,669	1872	40,000
1865	48,372	1869	54,867		

The value of the exports in 1870 was: bars, $8,067,178; regulus, $4,250,898; ore, $204,967; total, $12,523,043. The total product of the country is estimated as follows: in 1868, 46,500 tons; 1869, 55,000; 1870, 48,600; 1871, 44,900; 1872, 40,500. The mines at Corocoro, 15 leagues S. W. of La Paz, in Bolivia, yield abundantly, though without machinery for drainage or working. The native copper of the deposit, disseminated in sandstone, is extracted by crushing and washing. The product, known in commerce as barilla, was in 1869 from 3,000 to 3,500 tons of ore. Small quantities of copper are shipped from Peru to Great Britain.—The most productive mines of Australia are in South Australia, the largest being the Moonta and

* Also 3 water wheels of 70 horse power.

Wallaroo mines, on Yorke peninsula, which employ from 2,000 to 3,000 miners, and the Burra-Burra mine, employing about 1,000 hands. The exports from the colony of fine copper and ore from 1862 to 1871 were:

YEARS.	Fine copper, tons.	Ore, tons.	YEARS.	Fine copper, tons.	Ore, tons.
1862...	4,294	6,213	1867...	8,036	10,681
1863...	4,802	5,323	1868...	5,211	20,854
1864...	6,702	4,540	1869...	4,639	26,814
1865...	5,010	16,180	1870...	5,471	20,886
1866...	6,270	16,870	1871...	6,395	20,127

The value of the copper exports in 1871 was £648,569. In New South Wales in 1872 there were 18 copper mines, with a nominal capital of £831,000, and a subscribed capital of £460,240. The product of 1871 was 667 tons of copper, valued at £44,123; exports, 1,350 tons of raw copper, worth £87,575, and 1,370 tons of ore, worth £14,264. The imports into Great Britain from Victoria from 1867 to 1871 were:

	1867.	1868.	1869.	1870.	1871.
Ore and regulus, tons....	5,477	8,488	6,666	8,125	3,522
Value.....	£59,193	£84,630	£64,545	£91,813	£37,698
Unwrought and partly wrought copper, tons....	763	281	1,085	445	1,202
Value.....	£258,685	£20,160	£73,066	£27,700	£92,668

Small quantities of copper are also produced in West Australia.—There are copper mines in the Taurus, in Persia, India, Cochin China, and Japan. From the last named country considerable quantities are shipped to China and elsewhere in the East, the exports in 1870 from Hiogo and Osaka amounting to 1,290 tons, worth $426,375. Copper is likewise found in Morocco, in South Africa, and on the W. coast of that continent. The imports of ore and regulus into Great Britain from the Cape of Good Hope in 1867 were 5,935 tons, worth £108,534; in 1868, 2,843 tons, worth £62,407; in 1869, 4,628 tons, worth £92,155; in 1870, 6,926 tons, worth £118,155; in 1871, 6,414 tons, worth £143,812.—The total production of the world at different periods has been estimated as follows: in 1830, 25,500 tons; in 1840, 41,000 tons; in 1850, 54,700 tons. Simonin, in his "Underground Life," calculates the yield in 1865 to have been 65,000 tons, worth $500 a ton.

COPPERPLATE. See ENGRAVING.

COPPER SMELTING. With the exception of the native copper from Lake Superior, and smaller quantities from Peru and Bolivia, nearly all the copper of the world is obtained from sulphuretted or oxidized ores, which require for the separation of the pure metal a long and somewhat costly process. This is effected either in the dry or the wet way; that is to say, by operations in the furnace, or by processes which allow the copper to be separated in a dissolved form in watery solution, and subsequently precipitated therefrom. The term smelting applies more properly to the first process, but we shall briefly describe both the dry and wet methods.—The treatment of the native oxides and carbonates is extremely simple, requiring only their fusion with charcoal and a proper flux in a small blast furnace, by which metallic copper is at once obtained. In the case of the sulphuretted ores, which generally contain more or less iron and other foreign metals, the treatment is much more complicated, and depends upon the fact that the copper has a greater affinity for sulphur than the associated metals; so that if a double sulphuret of copper and iron be partially oxidized by roasting in the open air, and then melted in a furnace, the iron in an oxidized condition unites with the foreign matters to form a more or less fusible cinder or slag, while the copper, still retaining its sulphur, separates in the shape of a dense brittle mass known as regulus or matt. To facilitate this process, various ores are often mixed together in order to secure greater fusibility, and oxidized ores are sometimes mixed with highly sulphuretted ones, by which means the copper of both is got in the form of regulus. In some districts low-grade ores, of perhaps 4 or 5 per cent., are thus converted into a regulus of 30 per cent. or more, which is then shipped to some other place for further treatment. This regulus holds also any gold or silver which may have been in the ore, and hence the copper ores of Colorado, rich in precious metals, are there converted into regulus, which is sent elsewhere for further treatment. The regulus or concentrated copper ore thus obtained, still containing a portion of iron and sulphur, is again roasted and fused with some flux, whereby a richer regulus is obtained; and this operation is repeated until a nearly pure disulphide of copper results. For the extraction of the copper from this two plans are adopted. The first, still followed in Wales and in most European works, consists in partially roasting the refined regulus, by which a part of the sulphur is removed as sulphurous acid, and the combined copper is converted into oxide; and then causing the latter to react upon the yet unoxidized portion, the sulphur of which fixes upon the oxygen of the oxide to form sulphurous acid, while the copper of both is left in the metallic state. The reaction may be thus represented: $Cu_2S+2Cu_2O=Cu_6+SO_2$. The second plan consists in continuing the roasting and oxidation of the purified and pulverized regulus until the whole of the sulphur is expelled. The copper, being then in the condition of oxide or suboxide, is treated directly with charcoal in the same way as the native oxides and carbonates. The latter method, known from its inventor as Napier's, is now generally pursued in Chili, and is said to offer great advantages on the score of economy of fuel and labor over the older system. The copper ob-

tained by either of these processes is still somewhat impure, from the presence of small quantities of sulphur and foreign metals, chiefly arsenic, tin, iron, and sometimes nickel. To remove these it is fused in contact with the air, by which these are oxidized and the fixed oxides combine with the silicious matters of the hearth. In this process, however, the copper absorbs a portion of oxygen and holds in solution a quantity of suboxide, which impairs its malleability. This is removed by covering the surface of the melted metal with anthracite or charcoal, and stirring it with wooden poles, which by giving off reducing gases deoxidize the metal and give it the toughness of pure copper, after which it is cast into ingots. The details of these processes vary considerably with different ores and in different localities. The consumption of fuel in the treatment of copper ores is very great. Thus in the old Welsh process it is said that as much as 15 tons of coal is used in extracting one ton of copper from the low-grade ores of Cornwall. In Chili, however, owing to the great improvements introduced there, a ton of ingot copper is now made from ores of 13 per cent. with the aid of five tons of coal.—The extraction of copper from its ores by solution has been long known. The spontaneous oxidation of the sulphuretted ores in certain mines gives rise to solutions of sulphate of copper, which when brought in contact with metallic iron yield their copper in a metallic state, while the iron is dissolved. The copper thus obtained is in a granular, more or less crystalline form, and is known as cement copper. By the artificial oxidation, by roasting in furnaces or in heaps with burning wood, of sulphuretted ores, a large proportion of the metal is converted into sulphate, and may then be dissolved out by water. From the solutions thus obtained the copper is either thrown down by iron in the metallic state, or in some cases by lime as an oxide, or by sulphuretted hydrogen gas as a sulphide, to be subjected to further treatment. Other methods of rendering the copper soluble have been devised. Thus, in some cases, the naturally or artificially oxidized ores are directly treated with sulphuric or hydrochloric acid, by which the copper is dissolved as sulphate or chloride, and then precipitated by metallic iron. Another plan consists in calcining the ores with a portion of common salt, by which, with the aid of the oxidized sulphur, sulphate of soda and chloride of copper are formed. This is known as Longmaid's process, and has been extensively applied by Henderson in England to the treatment of the pyritous ores from Spain, of which several hundred thousand tons are annually imported into England and calcined in proper kilns for the extraction of the large amount of sulphur which they contain, which is used for the manufacture of sulphuric acid. The residues, still containing a little sulphur and from one to four per cent. of copper, are calcined with salt as above described, and give up to water, with the help of a little hydrochloric acid, the whole of their copper. The consumption of iron by these processes is considerable, amounting to from one and a quarter to two tons for each ton of copper produced. When the copper is present as sulphate, the resulting sulphate of iron is a valuable by-product. The protochloride of iron obtained when the copper is precipitated from its chloride has been converted by exposure to air or by chlorine gas into perchloride, and used to dissolve oxide of copper from oxidized ores. The occurrence of large quantities of low-grade copper ores in localities remote from cheap supplies of fuel has caused increased attention to be given to wet processes for the extraction of copper from its ores, and two newly devised methods have been brought forward and patented. The one, known as Monnier's, differs from that of Longmaid in substituting sulphate of soda for chloride of sodium in the calcining furnace. By this means it is possible to convert the whole of the copper in a sulphuretted ore into sulphate, which is then decomposed by metallic iron, or, as has been lately proposed, is partially separated by a process of concentration from the sulphate of soda, and then decomposed by calcination with charcoal. The other, known as the Hunt and Douglas process, is based on a new principle, and applied either to native oxides and carbonates or to the artificially prepared oxides resulting from the roasting of sulphuretted ores. Protoxide of copper reacts with protochloride of iron to form peroxide of iron and a mixture of protochloride and dichloride of copper: $3CuO + 2FeCl = Fe_2O_3 + Cu_2Cl + CuCl$. The dichloride is insoluble in water, but readily soluble in hot and concentrated brine; and from the solution holding the two chlorides of copper, the metal is readily thrown down by metallic iron, regenerating the protochloride of iron, with a consumption of about two thirds of a ton of iron for a ton of metallic copper. In practice the ores (oxidized if necessary by roasting) are digested with a hot brine mixed with protochloride of iron; and the resulting solution, being brought in contact with metallic iron, gives up its copper, and is then ready for the treatment of a fresh portion of ore. The cement copper thus obtained is very pure, and is readily melted down into ingot copper. The small quantities of silver very often present in copper ores are dissolved in the form of chlorides in the Hunt and Douglas and Longmaid processes, and may be economically separated therefrom by the ingenious process of Claudet, which consists in precipitating the silver in combination with iodine.—Swansea in Wales, which is in a coal district, has been for a long time one of the great copper-smelting centres, and receives the ores and regulus not only of Cornwall, but from many other parts of the globe. In former years much of the copper ore from Chili was carried to England for smelting, but

it is now in great part smelted at home, although in 1870 two thirds of the copper produce of that country was sent to Swansea in the shape of regulus. Large quantities of ores from Australia, South Africa, Cuba, and British North America are shipped to England for treatment. The smelting works of Great Britain are the most extensive on the globe. In 1871 there were 24 copper mills, employing 3,525 hands; of which 13 were in Glamorganshire, 3 in Carmarthenshire, 3 in Surrey, 2 in Staffordshire, 2 in Worcestershire, and 1 in Anglesey. According to the census of 1870, the United States contained 27 establishments for milling and smelting copper, with 43 steam engines of 3,244 horse power, 1 water wheel of 39 horse power, and 1,082 hands; capital, $3,158,500; wages paid, $577,129; value of materials, $10,715,400; value of product, $11,684,123. They were thus distributed:

STATES.	Establishments.	Hands.	Capital.	Value of products.
Maryland	1	127	$800,000	$1,016,590
Massachusetts	1	97	500,000	544,850
Michigan	19	636	1,591,000	9,260,976
Rhode Island	1	25	65,000	335,920
Tennessee	2*	188	130,000	510,677

The other 3 (1 in Arizona and 2 in California) were unimportant. The Maryland works are in Baltimore co., the Massachusetts works in Bristol co., the Rhode Island works in Newport co., and the Tennessee works in Polk co. Of the Michigan works 12, employing 511 hands, and producing $6,752,228, were in Houghton co.; 1, with 62 hands, producing $2,003,760, was in Wayne co.; and 6 (quartz mills), with 63 hands, producing $504,988, were in Keweenaw county.

COPPET, a village of the canton of Vaud, Switzerland, on the lake and 9 m. N. of the city of Geneva; pop. 500. In the château of Coppet the philosopher Bayle was at one time a teacher in the family of Count Dohna. The château was afterward the residence of M. Necker and of his daughter Mme. de Staël; and it is at present a summer residence of Baron Rothschild.

COPROLITES (Gr. *κόπρος*, dung, and *λίθος*, a stone), the fossil excrements of various kinds of fishes and saurians, first recognized as such by Buckland. They are found, sometimes in enormous quantities, in several geological formations, as the tertiary, chalk, oölite, lias, and carboniferous, scattered among the other fossils in these rocks, and sometimes met with enclosed among the ribs of the fossilized ichthyosauri. They occur to some extent in this country in the greensand and coal formations, but in England most abundantly in the lias. They vary greatly in size, some being the product of the largest ichthyosauri, and containing within them scales and bones of fishes and other animals which served as food to these monsters; while some belonged to smaller individuals, and are now seen in stony lumps of only an inch or two in length. Their color is whitish, grayish, and from this to black. On their surface are still impressed the marks of the tortuous wrinkles of the intestines. The animal remains preserved in the coprolites indicate the prey of these fishes and saurians. The larger kinds appear to have fed upon the smaller of their own species; and these, from the bones found in the coprolites of the largest ichthyosauri, could not have been less than 7 ft. in length. A remarkable instance is given by Dr. Buckland of the minute accuracy with which the principles of comparative anatomy are applied to investigations of this nature. A small scale of a fish seen upon one side of a coprolite was shown to Prof. Agassiz, who at once recognized it as belonging to the extinct species *pholidophorus limbatus;* and from a minute tube upon its inner surface, hardly discernible without a microscope, he observed that it must have been on the left side of the body near the head. This tube passed through the scales from the head to the tail of the fish, conveying a lubricating mucus.—Different coprolites differ considerably in chemical composition; those containing much phosphate of lime are very valuable as fertilizers, and are used as such. In the following table the first and fourth columns of figures give the composition of the coprolites of the coast of Suffolk; the second column, those found in the ironstone of Burdiehouse in Scotland; the third, those found in the limestone of Burdiehouse, according to A. Connel; the fifth, those over the lias near Stuttgart, Germany; the sixth, those from Bohemia:

CONSTITUENTS.	1.	2.	3.	4.	5.	6.
Phosphate of lime	56	10	85	16	68	15
Phosphate of iron	14	6	....	14	6	....
Carbonate of lime	21	61	11	40	17	5
Alumina	4	....	....	7	....	....
Silex	2	....	....	10	6	....
Carbonaceous matter	1	4	4	10	1	74
Moisture	2	5	....	2	2	1
Carbonate of magnesia	....	14	.. .	1	....	3
Chloride of sodium	....	....	....	....	...	2

The varying chemical composition of this mineral is to be expected from its origin; the form and color also differ greatly, but the specific gravity is always between 2·6 and 2·8.

COPTIC LANGUAGE (Sahidic, *Mentkyptaion* or *Aspi en Kēmi*, language of Egypt; Ethiopian, *Gbetze;* Arabic, *Keft*, in which also the Coptic people are called *Ghipt*). Some writers, following the Moslems, derive the name Coptic from *κόπτειν*, to cut, to circumcise; Wilkins and Pococke from Koptos, a Thebaic nome on the Nile; others from the Jacobites, a body of heretics who were called Coptes, under Heraclius (A. D. 610–641); this is the prevailing theory of Roman Catholic authorities. Others hold that Copt was the name of the son of

* Quartz mills.

Misraim, the founder of Egypt, and that it has descended from him to all the native race; this is the legend of the convents, and the boast of the Coptic people. But since Renaudot, the most eminent Egyptologists have agreed in deriving it from Αἴγυπτος (according to Brugsch, in ancient Egyptian, *Ha-ka-ptah*, house of the worship of Ptah), whose sacred language was the mother of the Coptic, by which alone we are now enabled to understand the Egyptian monuments. This ancient sacred language coexisted with a vernacular dialect, and out of the two, with a mixture of Greek and Arabic words, arose the Coptic, which may be dated from the time of the Ptolemies in Lower Egypt; the version of the Gospels in it having been read by St. Anthony, who did not know Greek, about the year 271. The language was used in Lower Egypt until the 10th century, and in Upper Egypt until the middle of the 17th, when it altogether gave way to the Arabic, except in the monasteries, where it was still preserved. With Christianity the Copts adopted not only the Greek religious nomenclature, but the Greek alphabet as well, even introducing the forms of such letters as *g*, *d*, *z*, *x*, and *ps*, though these sounds do not occur in genuine Coptic. Thus in the Coptic alphabet there are 32 signs, including these intrusive Greek letters; a numeral sign for 6 inserted after *e;* six Egyptian letters derived from hieroglyphs (and representing two forms of *sh*, *kh*, *h*, *f*, and the English *j*); and a syllabic sign for *ti*. Strictly speaking, however, there are 21 Coptic sounds, viz.: *a*, *e*, *i*, *o*, *u* (which was written *oy*), all pronounced as in Italian, with *y* sounded as a French *u;* *b*, *k*, *l*, *m*, *n*, *p*, *r*, *s*, *t*, *f* (also written *ph*), *h*, the German *ch*, the English *sh* and *th*, and the English *j*. Diacritic signs were used; thus a horizontal line over numerals, over contracted words, and over $\overline{m}$ and $\overline{n}$, which are then to be read *em* and *en*, &c. The language has three dialects, viz.: the Memphitic, or genuine Coptic, which abounds in aspirates, writes *ai* for *ei*, and loves the final *i;* the Sahidic or Theban, which uses the final *e*, and writes *ei* instead of *ai*, and in which the *Pistis Sophia*, a Gnostic work, is written; and the Bashmuric, belonging to the two oases, the poorest of the three in literature, using *a*, *e*, *ē*, and *l* respectively, instead of *o*, *a*, *ĕ*, and *r*. —All simple words are monosyllabic, unless lengthened by additional vowels; *e. g.: ape*, head; *ohi*, to stand; *mash*, to strike; *pēt*, to run; *ro*, mouth, &c. Verbs become passive by a change of their vowel into *ē: kō*, to put; *kē*, to be put. There are doubled roots, as *shorsher*, to destroy (*shor*, to throw away); words inserting a vowel, prefixing *a*, *en*, *sh*, or suffixing *r*, *s*, *f*, *sh;* compounds of two words, as *sek-mōu*, to draw water, *rem-ne-kahi* (man-of-land), inhabitant, *tsa-bo* (*ti*, give, *sbo*, learning), to teach, *ham-she* (man-wood), carpenter, &c.; and compounds with the following prefixes: *at-nay*, invisible, *la-foi*, very hairy, *ment-*(or *met*)*-at-nute* (-ism a-the-), atheism, *ref-sōnt* (-or creat-), creator, *shu-taio*, worthy (of) honor, *shin-nay*, to see; hence nouns by *pi-*, *er-*, as *pi-shin-nay* (-ing see-), vision, *an-* (much, again) *-thba*, myriad, &c. Nouns are formed by prefixing *at*, *ma*, *met;* thus: *ma-nesō* (place-drink), inn; *met-athmu* (-ity immortal-), immortality. Many hieroglyphs are thus compounded: MT-S (Copt. *met-sei*), ornament; MT-KT (*met-kōto*), circuit; MT-STN (*met-suten*), kingdom. The MT expresses our -ment, -dom, -ity, -ism, &c.—There are but two genders. The feminine is often formed from masculine by a vowel change, or by suffixing *e* (*i*, Memphitic), or by an article or adjective; thus: *urō*, queen (from *uro*, king); *hinb-i*, ewe-lamb; *alu-shime*, female child; *alu-hout*, male child. The articles are indefinite, definite, and demonstrative. The former are of common gender; as, *u rōmi*, a man; *han-mui*, some lions. The definite articles are *pe* (*pi*, M.), corresponding to French *le; te* (*ti*), to Fr. *la;* and *ne*, *nei* (*ni*), to Fr. *les;* thus: *pi-son*, *le frère; ti-sōne*, *la sœur; ne-tay*, *les montagnes*. They often drop the final vowel, as *pnute*, *le dieu*. Before initial *h* the corresponding aspirates occur, as in Greek; thus, *th-orasis*, ἡ ὅρασις. In hieroglyphs the prefix P stands for *le*, and N for *les*, but the suffix T for *la;* thus MU-T (Copt. *ti-mau*), *mère la*. The demonstrative articles, either joined or not, are *pei*, Lat. *hic; tei*, Lat. *hæc;* and *nei*, Lat. *hi*, *hæ*, *hæc*. In hieroglyphs and Memphitic, they are PAI, TAI, NAI. Possessive adjectives are formed of the definite article and of the suffixes *a* (to have), and *e* (to be, *être à*, to belong to); thus: *pa*, Fr. *le mien; ta*, Fr. *la mienne; na*, *les miens* and *miennes;* analogous are *pek*, *tek*, *nek*, Lat. *tuus*, *tua*, *tui*, masculine; *pu*, *tu*, *nu*, the same for feminine; *pef*, *tef*, *nef*, his, her, their, masc.; *pes*, *tes*, *nes*, fem.; *pen*, *ten*, *nen*, Lat. *noster*, &c.; *peten*, &c., Lat. *vester*, &c.; *pey* (*pu*), &c., their; *e. g.: pa-nuti*, my God; *pen-hēt*, our heart; *tek-shom*, thy power. The hieroglyph RN-F is for the Copt. *pef-ran*, his name. Foreign and many Coptic nouns are without a plural form; thus: *ni-apostolos*, the apostles; *han-magos*, some magi; Copt. *pei-hou*, the day; *nei-hou*, these days. Many Coptic nouns become plural by suffixing *i* (*e*, Sah.) to consonants, or by lengthening final vowels; as *apey*, heads; *urō-u*, kings; *sbō-ui*, doctrines. Hieroglyphs trebled the noun, or added three lines, or final diphthongs; thus: KM-UI, Egyptians; MR-UI, regions. Some are anomalous; thus: *eiot*, father, *eiōte*, fathers; *hurit*, guardian, *hurate*, guardians; *son*, brother, *sney*, brothers. Others are more dissimilar, as *shime*, woman, *hiōme*, women; *bōk*, servant, *ebiaik*, servants; *iom*, sea, *amaiōu*, seas. The cases of declension are signified both by separate particles and by prefixes. The nominative sign is *enshi* (S. and B.), or *enje;* the genitive, *ente*, *en-*, *em-;* the dative and accusative, *en-*, *em-*, *è-*, *ō-;* vocative, *pe;* the ablative, *ebol*, *hiten*, *en-*, *em-*, *e-*, and many prepositions.

The hieroglyphic genitive is N, NT, M; dat., N, R, L, HR (Copt. *haro*, to); acc., N; abl., M, out from, EM, by, for, MT (Copt. *mut*, to join). Adjectives become names of origin or of quality by means of *en;* thus: *rem-en-Kēmi* (man of Egypt), Egyptian; *rem-en-nuti* (man of God), pious. To form the feminine adjectives, add *i* (*e*) to the masculines, or lengthen the final vowel. The plural of adjectives is formed like that of substantives. Some adjectives receive personal suffixes, as *ter-k*, whole-thou; *naa-s*, great-she. The comparative degree is denoted by *huo*, corresponding to the Gr. *μάλλον*; the superlative by *khen*, in, *ute*, between, *ebol-ute*, before, *emate* (*emastrō*), very, much, and by the Gr. *-ιτος*. In ancient Egyptian, the genitive plural (as king of kings), and *enhme*, *estrate*, and *èhote*, indicated plurality. The numerals are: 1, *ua*, masc., *uei*, fem. (*uai*, *ui*, M.); 2, *snay*, *sente* (*snuti*); 3, *shoment*, *shomte;* 4, *ftou*, *fto;* 5, *tiu*, *tie;* 6, *sou*, *so;* 7, *sashsf;* 8, *shmune;* 9, *psit;* 10, *mēt;* 20, *juōt;* 30, *maa'k;* 40, *hme;* 50, *taiu;* 60, *se;* 70, *shbe;* 80, *hmene;* 90, *pēstaiu;* 100, *she;* 1,000, *sho*, &c. Ordinals: 1st, *ti-aphe* (beginning), *shorp*, &c.; the others are formed by prefixing *mah* (MH) to the cardinals. Distributives are made by doubling the cardinals; multiples by adding *sop* (times); fractions by prefixing *re* (R) with *fre*, part. The personal pronouns are: *anok*, I; *entok*, *ento* (masc. and fem.), thou; *entof*, he; *entos*, she; *anen*, we; *entoten*, you; *entōu*, they. Possessive demonstrative pronouns consist of the article with *ō* (to be) and personal suffixes; thus: *pōi* (the-is-me), my; *pōk*, *pō* (masc. and fem.), they; *pōf*, *pōs*, his, her; *pōn*, our; *pōter*, your; *pōu*, their. The demonstratives *pē*, *tē*, *nē* correspond to the Lat. *ille*, *illa*, *illi*. The relative *et*, who, which, what, is indeclinable. The interrogatives *nim*, *eut*, correspond to Lat. *qualis;* *uer*, to Lat. *quantus*, *quot;* and *u*, to Lat. *quid*. Verbs indicate persons either by suffixes, as *i*, I; *k*, *e* (masc. and fem.), thou; *f*, *s*, he, she; *n*, we; *ten*, you; *sen*, they; or by the prefixes *ti*, *k*, *te*, *f*, *s*, *ten*, *teten*, *se*. Particles of tenses are, for the present, *ei*, Lat. *sum;* *ek*, *ere* (masc. and fem.), Lat. *es;* *ef*, *es*, Lat. *est;* *en*, *sumus;* *ereten*, *estis;* *ey*, *u*, *ere*, *sunt*. The perfect indefinite is *ai* (have-I), Lat. *fui;* *ak*, *fuisti*, &c. The imperfect, *ne* (*venit*), like the Fr. *venir de*, is inflected thus: *nai*, *nak*, *nere*, *nef*, *nes*, &c. *Pe* following denotes simultaneity, as *nai-ke-kahey pe*, I was at the same time naked. The future is indicated by *e-*, *-ē*, *eiè*, *ekè*, &c.; the second future (soon) by *na*, to go, or *ei*, toward, as *ekna*, thou wilt be soon; and the pluperfect by *naina*, Fr. *j'allais*. *Sha* denotes habit; thus: *shai*, *soleo;* *shak*, *soles*, &c. The subjunctive is distinguished by *en-*, that, as *entirashi*, Lat. *gaudeam;* the optative by *marei* (*velle*), I wish, by *ma*, grant, or by *pe*, to be, as *marekōnh*, *utinam*, *vivas;* the imperative is the root alone, or with the prefix *a*, be it, or *ma*, give, as *ajas*, say; the infinitive is the root and used as a substantive; the present participle has the prefix *e* or *et*, who, as *pilaos ethemsi*, the people sitting. Particles are joined to tenses; thus: *entcrei-tōm*, when I close; *shantei-enjoos*, as long as you say. Other particles are *ēnei*, if, *shan*, if so that, and *empati*, before that. Negation is indicated by prefixing *en*, *empe*, *empate*, or by affixing *an*, or by inserting the verb between *en* and *an*. Endings of the sacred dialect are -I, I; -K, -T (masc. and fem.), thou; -F, he; -S, she; -N, we; -TN, you; and -SN, they. Its auxiliary verbs are E-, A-, O-, UON-, to be, and ER-, to do, to make. The prepositions are: *è*, in, of, from; *èbol*, *ebolhiten*, out, through; *èhote*, before, above, on; *nem*, with; *enten*, of; *sha*, till, to; *kha*, under, against; *ha*, under, to; *haten*, near by, with; *hi*, in, on, &c.; which are lengthened by such suffixes as *rat*, *tot*, *rō*, *ma*, *fēt*, *ō*, &c. Adverbs are made by prefixing *è* to nouns; thus: *èphlēu*, in vain, *èpehou* (on the day), daily; or by prepositions, as *khen u rashi* (in a joy), gladly. The most frequent conjunction is *jè* (saying), that, because, whereas. Others are *shantei*, while; *enei*, *eishan*, if; *empati*, before that; and many Greek ones with their own signification, as *de*, *te*, *alla*, *an*, *eti*, *ana*, *kata*, *hina*, &c. The hieroglyphic prepositions are N, Copt. *en;* NT, *ente;* HR, *haro*, to; HT, *hahte*, near; RM, *erem*, with, near, by. The construction is strictly logical, the subject being followed by the verb and this by the regimen. Specimen: *Pen iōt*, *et khen* (*noster pater qui in*) *ni* (article) *phēuì* (*cœlis*): *Maref-tubo* (*utinam sanctum*) *enje* (article) *pek ran* (*tuum nomen*). *Maresì* (*veniat*) *enje pek meturo* (*tuum regnum*), &c.—Translations of portions of the Coptic Scriptures, of Gnostic odes, and inscriptions have been made by Huntington, Pococke, David Wilkins, Tuki, Giorgi, C. G. Woide, F. Münter, Mingarelli, Zoëga, Quatremère, Engelbrecht, H. Tattam, L. Ideler, G. Seyffarth, Schwartze, P. Bötticher, Champollion-Figeac, Mariette, Brugsch, and others. Peiresc was the first European student of Coptic. Saumaise and Scaliger made little progress in it. Athanasius Kircher (1636–'44) devoted some attention to it, but fell into many errors. Waldoni (1653), E. Vinding (1660), Bonjour (1699), Blumberg (1716), Tuki (1778), Scholtz (1778), and Didymus Taurinensis or Valperga (1783) wrote on the grammar and lexicography. The *Opuscula* of Jablonski contain an excellent glossary. Important contributions are furnished by the *Recherches critiques et historiques sur la langue et la littérature de l'Égypte*, by Quatremère (Paris, 1808); the "Grammar of the Egyptian Language," by Tattam (London, 1830), with an appended dictionary by Young; and the grammar and dictionary of Champollion the younger. Rosellini's treatise on the Coptic language (Rome, 1837) was to a large extent copied from Champollion. An excellent survey of the history of the study of Coptic is given by Félix Nève, *Des travaux de l'érudition chrétienne sur les monuments de la langue copte* (Louvain, 1860). Among the latest and

best grammars are those of Peyron (Turin, 1841); of Benfey (Leipsic, 1844), showing the relation of the Coptic to the Semitic languages; of Schwartze, edited after his death by Steinthal (Berlin, 1850); of Uhlmann (Leipsic, 1853); of Seyffarth (Gotha, 1855); and of Schrader (Göttingen, 1860). The best vocabularies are those of Vessière de la Croze (edited by Woide, Oxford, 1775), Rossi (Rome, 1808), Tattam (Oxford, 1835), Peyron (1835), Parthey (Berlin, 1844), and Brugsch (Leipsic, 1867–'8). For a reading book there is the *Pistis Sophia*, published by Petermann (Lat. version by Schwartze, Berlin, 1851), and the *Liber Henoch æthiopice*, edited by A. Dillmann (Leipsic, 1861). Valuable contributions appear from time to time in the monthly periodical edited by Lepsius and Brugsch, *Zeitschrift für ägyptische Sprache und Alterthumskunde*, which has been published at Leipsic since 1864.

COPTIS, gold thread, a genus of the natural order *ranunculaceæ*, which inhabits the northern regions of this continent and of Asia, and is found in Greenland and Iceland. *C. trifolia*, the only native species, is a pretty little evergreen, growing in moist woods, which derives its English name from the bright yellow color of its slender roots. The yellow color, as well as the bitterness which pervades the whole plant, and especially the root, is due to the presence of the alkaloid berberina. Its virtues are simply those of a mild bitter tonic. In New England it is employed as a local application in ulcerations of the mouth.

COPTS, the principal sect of Christians in the valley of the Nile. Ethnologically, the Copts are the representatives of the native race which inhabited Egypt in the time of the Ptolemies. The race, however, has been mingled somewhat with the blacker tribes of the upper Nile, and with its Greek and Arab conquerors. In physical characteristics the Copts resemble much the Moslems in Egypt, but they are smaller in stature and have a less independent bearing and manner. As a general rule their complexion is dark brown, almost approaching to black. The nose is straight, widened at the end; the eyes, which incline upward, are black, the forehead is narrow, and the hair curly. Their dress is of dark colors, both in the turban and flowing robe, either of brown, dark blue, or black. In the towns and cities this is an invariable distinctive mark, but in the villages of Upper Egypt the attention to costume is less scrupulous, and the Copt women cannot by dress be distinguished from the Moslem. The cross, tattooed upon the hand of the Copt woman, is a more decisive badge; and for the man an inkhorn at the girdle is another badge, since the work of scribes and clerks in Egypt is almost wholly in the hands of Copts. Their education is usually much superior to that of the Moslems, and they are more apt in those pursuits which require quickness of sight and readiness of invention. Unlike the Moslems, also, they drink freely of spirituous liquors. In the matter of food their customs are in many respects identical with those of the Jews. They will not eat things strangled, nor blood, nor the flesh of swine; and above all things, they shun camel's flesh as unclean. With the other races of Egypt they now seldom intermarry, such connection being prohibited by the ecclesiastical law.—They are devotedly attached to their ecclesiastical system, and hold that their ritual is the most ancient Christian ritual in existence. They reckon in their list of saints an evangelist, with many of the most celebrated fathers and doctors of the church. They stigmatize as heretical the communions of Greece and Rome; and they regard with intense hatred those of their own countrymen who recognize the authority of the pope or the Byzantine patriarch. The church has so diminished in numbers that

A Copt.

it is computed to have in all Egypt not more than 150,000 members. It has five orders of active and secular clergy, besides the order of monks, which holds a very important relation to the rest of the church. Historically the church of Egypt is a monastic church. The beginnings of the monastic life were in its deserts; and the hermits and cenobites of the Thebaid and the Red sea coast gave the example and the impulse to all subsequent development of Christian asceticism. The head of the Coptic church is the patriarch of Alexandria, who originally resided in that city; but the patriarch Christodulos (1045–'76) transferred his seat to Cairo, where his successors have a palace, and derive a large revenue from their possessions. The patriarch holds office for life, and his authority in the church is almost absolute. Formerly he was elected by a synod of 12 bishops convened at Cairo; but at present he is selected from among the monks of the

convent of St. Anthony, near the gulf of Suez. The mode of election is as follows: A list is made out of 100 monks who are believed to be fit for the office of patriarch. Out of this number 50 are elected by a majority of votes; this number is then by vote reduced to 25, subsequently to 10, and at last to 3, one of whom is chosen by lot. He must continue unmarried and conform to his monastic customs of dress and diet and sleep. He appoints the *abuna* or head of the Abyssinian church as his suffragan. The bishops are 13 in number, and like the patriarch wear the broad round turban and are celibates. It is customary to choose them from the convents, though the canons of the church do not always require this. The youngest among the dioceses are that of Esne, an important place for the Abyssinian trade, established in the 18th century, and that of Khartoom, which embraces all Nubia, and was established in 1835. Below the bishops are the archpriests, who are sometimes at the head of the convents, and sometimes are chosen directly from the order of the priesthood. Their functions correspond to those of archdeacons in the English church. Next to these are the priests, who may be married, provided the marriage has taken place before their ordination. After that they are not allowed to marry; nor can any one be ordained a priest who has had more than one wife, or has married a widow. The priest wears a turban of peculiar shape, narrow in the rim and flattened at the top. He is not compelled to abstain from secular labors, but may earn money by a trade or a profession. The same rules apply to the *shemma*, or deacon, who is only an incipient priest. Both priest and deacon receive ordination from the hands of the bishop, or, if they live in Cairo, from the patriarch. In reality most of them, especially in Lower Egypt, are unmarried, their ranks being chiefly recruited from the convents.—The Coptic convents were once very numerous, 336, according to the legend. They were distributed through the desert of Nitria, the Thebaid, the shores of the Red sea, Nubia, and along the Nile. The sexes were separate, and nunneries were as common in Egypt as in Italy or Spain. At present their number is greatly reduced. Of monasteries proper, in which only men are admitted, there are but seven, those of St. Anthony and St. Paul in the eastern desert, four in the desert of Nitria, and one at Mount Koskam in Upper Egypt. In these the monastic rule is rigidly observed, and the old customs are kept in their integrity. In Cairo there are three convents; in Fostat or Old Cairo, and in Alexandria, two each; two in the Fayoom, where once there were 30 or more; and one in Abu Honnes, Mellawi, Ekhmin, Girgeh, Negaddeh, and other towns along the river. The best known to travellers is the Deyr el-Adra, or convent of the Virgin, which crowns the summit of a precipitous rock, the Jebel et-Tari, on the E. bank of the Nile. The white and red monasteries near Soohag are also frequently visited on account of the remarkable architecture of their churches. In the neighborhood of Abydos there is also an important convent. But in all these establishments the monks have lapsed into secular habits, the fasts are much neglected, women live with the men, and the convent is only a Christian village of greater or less extent. In the regular monasteries, such as those of Nitria and of St. Anthony and St. Paul, hard and long probation is required before initiation, and the discipline is severe. The dress is a simple shirt of coarse woollen fabric. The badge of the class is a dark blue strip of cloth, which is suspended from the turban below the back of the neck. Only on feast days is animal food allowed, and then in small quantities; the ordinary food of the brethren is black bread and lentils, and on fast days they are deprived even of this meagre fare. The convents, when not situated on some inaccessible rock, are surrounded by a high and strong wall, which has only a single iron door, and in some cases is wholly without opening, the means of entrance being a pulley from the top. In the neighborhood of these convents are the ruins of many others.—Baptism, a rite to which the Copts attach great importance, is performed by dipping the child three times into water which has received a few drops of consecrated oil. An unbaptized child will be blind in the next world. The rite ought to be administered to a male infant 40, and to a female 80 days after birth. It secures regeneration. Next to baptism is circumcision, which is performed upon boys at the age of seven years, though without any special religious ceremonies. It is more scrupulously attended to at Negaddeh than at Cairo. The Copts are as careful to observe their seasons of daily prayer as the better class of Moslems. Seven times a day they perform their lustrations, turn to the east, recite their *Pater noster*, and beg in 41 repetitions for the Lord's mercy. Their rosary contains 41 beads. Many of them go over in these seven daily exercises the whole of the Psalms. The public religious service is excessively long, lasting at least three hours before the consecrated cakes, stamped with the sign of the cross and the pious inscription, can be distributed to the people. It is accompanied by monotonous chantings, abundant burning of incense, processions of the host around the church, and the noisy beating of cymbals at intervals.—Like all orientals, the Copts decorate their houses of prayer with ornaments of ostrich eggs, rude inscriptions, and pictures of their favorite saints. Chief among these are the fighting St. George, and the hermits Anthony and Paul and Macarius, the last of whom is the especial protector of the Nitrian convents. The form of the churches and the general style of Coptic architecture is that of the Greek basilica; none of their churches are cruciform. In many instances ancient heathen temples

were converted into Christian churches. Some of the churches are still subterranean; and at Thebes a church of the catacombs has been discovered hardly less interesting than the churches beneath St. Agnese and St. Sebastian at Rome. In the ordinary construction of Coptic churches there are four compartments. At the furthest end from the doorway is the chancel, the *heykel*, which is completely hidden behind a high screen, with the doorway in the centre closed by a curtain, on which a cross is embroidered. Next to this is the part appropriated to the priests who interpret in Arabic the Coptic service to the singers, to the leading men of the congregation, and to strangers who may be present. This is separated from the next compartment by a high lattice, in which there are three doors. In this third compartment, which communicates directly with the street, are stationed the mass of the congregation. A fourth compartment in the extreme rear, or on one side, is reserved for the women. This is dimly lighted, and separated from the main room by a lattice-work partition. The women wear their veils during worship. The poor of the congregation wait during the service around the outer doorway, and receive alms as the congregation passes out. As in the mosques, every worshipper must take off his shoes before his feet touch the mats of the holy house, and must go at once to kneel before the cross on the curtain. The more devout then go round and pray in turn before the pictures of the saints, which are hung around the second apartment, giving a kiss to those within reach of their lips. During most of the service the congregation remain standing, or rather leaning upon long crutches, with which most of them are provided. The service within the heykel or sanctuary is entirely from the Coptic liturgies. No other tongue is allowed before the altar. The priests who officiate here wear ornamented vestments specially appropriated to the various religious seasons and festivals. The ordinary celebration of the eucharist requires two or three priests within the heykel, while as many more explain the lessons to the people in the next apartment. The communion is given to the clergy in both kinds, but the laity are privileged only to have cakes on which the wine has been sprinkled. The more devout confess their sins to the priests at least once in every week; and none have a right to ask for the sacred bread until they have eased their minds by such acknowledgment. The penances imposed are similar to those in the Roman church.—The regular seasons of fasting in the Coptic church include more than half the year. With the exception of the 50 days between Easter and Pentecost, every Wednesday and Friday throughout the year are "meagre days," in which meat is prohibited. Besides these, there are the fast of the Nativity, 28 days long; the fast of the Apostles, which follows the Ascension festival; the fast of the Virgin, 15 days in length, to prepare for the feast of the Assumption; and the great fast of Lent, which, with the additions that various patriarchs have made, and the preliminary fast of the prophet Jonah, extends to 58 days. In these fast seasons there is a daily service in the church, and the houses of worship are kept constantly open. There are seven principal festivals: those which commemorate the nativity, the baptism, the triumphal entry, the resurrection, and the ascension of Christ, the Pentecost miracle, and the annunciation to the Virgin. All of these festivals occur within the first half of the year, two of them in January, and the remaining five usually in April, May, and June. At the feasts *el-Milad*, Christmas, *el-Ghitas*, the baptism, and *el-Kabir*, Easter, there is a midnight service in the churches. The feast of baptism is still further honored by the custom of plunging into the river, or into a tank in the church, after prayers have been said and the water duly blessed. The men and boys together go through this ceremony, which is accompanied by a washing of the feet, performed by the priest. Besides these principal festivals, there are the feast of the Apostles, the holy Thursday and Saturday of Passion week, and the *Salib* feast in September, which commemorates the finding of the true cross. These feasts are marked by unusual show in dress, by largesses to the poor, and by indulging in ardent spirits to the degree often of intoxication.—The Copts have a convent in Jerusalem and a chapel in the church of the Holy Sepulchre, and there are perhaps 100 of their communion who reside in the holy city and welcome the pilgrims in their annual visit. The duty of pilgrimage is as binding upon Copts as upon Moslems; but the number of those who fulfil it is comparatively small.—The creed of the Coptic church is that of the Monophysites, who were condemned as heretics at the council of Chalcedon in 451. They deny the doctrine of two natures in Christ, and insist that after the incarnation there was but a single nature and a single will. In common with the Greeks, they hold that the Holy Spirit proceeds from the Father alone. It is affirmed by some writers that they believe the doctrine of transubstantiation; but this is denied by the Coptic priests, who hold to a theory more like the Lutheran than the Catholic. The number of sacraments is seven, but these differ in several particulars from the Roman sacraments, faith and prayer being substituted for matrimony and extreme unction. They acknowledge as authoritative only the three councils of the church which preceded the council at Chalcedon, viz.: of Nice, of Constantinople, and of Ephesus. The general name by which the Egyptian church is known in controversy is that of Jacobite, which name was applied to them as the followers of the Eutychian Jacobus Baradæus, one of the chief apostles of the heresy. This heresy they share with the Abyssinians, with whom indeed in most particulars of doctrine

and practice they sympathize. There is a convent of Abyssinian monks in the Nitrian desert; they share the same chapel at Jerusalem; and the abuna of the church of the mountains is dependent on the head of the church of Egypt.—Portions of three separate versions of the Scriptures into the Coptic tongue have been found among the MSS. brought from the Egyptian monasteries, which were probably made in the beginning of the 4th century. Of these, that used in Lower Egypt and the Nitrian desert is called the Memphitic; that used in Upper Egypt, the Thebaic; and the third, which it is conjectured may have been used in the eastern part of the Nile delta, the Bashmuric. The Thebaic version, which is often called the Sahidic, is the most important in the textual criticism of the New Testament; while the Memphitic, which is usually styled the Coptic, has the most authority in the existing Egyptian church. The first printed edition of the Memphitic New Testament was issued by David Wilkins (4to, Oxford, 1716), with a Latin translation. A later and more accurate edition was begun by the Prussian Schwartze in 1846, but only the four Gospels were published before his death. Since 1852 Dr. Paul Bötticher of Halle has published the Acts of the Apostles and the Epistles. Another edition, under the superintendence of Dr. R. T. Lieder of Cairo, has been published by the London society for promoting Christian knowledge. The Thebaic version has been collated and fragments of it published since 1779 by Woide, Mingarelli, Giorgi, Münter, and Ford. Fragments of the Bashmuric version have been published by Zoëga and Engelbrecht.—The Copts have three liturgies. The principal is a translation from the Greek liturgy of St. Basil, in which, however, several alterations are made to adapt it to the variations in doctrine and discipline. Another, which bears the name of St. Gregory, was probably borrowed from the Armenian church (of which Gregory was the apostle and founder), after that church lapsed into the Eutychian heresy. A third is doubtfully attributed to the Alexandrian Cyril, who in all the churches of Egypt has great authority, and is honored by the pompous title of "doctor of the world." Of these liturgies there are Arabic translations in use in all the churches. Most of the priests are unable to understand their sacred dialect except in a translation. (See Coptic Language.) —In 1442 the Copts were prevailed upon to enter into communion with Rome; but the union was soon dissolved. In 1713 the Coptic patriarch again recognized the supreme authority of the pope, but this act appears not to have had any lasting results. The missionaries of the Roman Catholic church, in particular the Franciscans and reformed Minorites, succeeded in gaining over a number of Copts for a reunion with Rome, and thus established a united Coptic church, for which the pope in 1781 instituted a vicariate apostolic, which still exists. The vicar apostolic, who is a bishop *in partibus*, resides at Cairo, and in his house young men who wish to devote themselves to the ministry receivè free board and instruction. Since 1840 the vicar apostolic has also had under his jurisdiction as delegate of the apostolic see the church of Abyssinia, to which country the Propaganda at that time intended to send a bishop of the Coptic rite. The number of united Copts is estimated at about 3,500, who have 9 churches, 7 chapels, and 25 priests.—The average morality of the Copts in Egypt is about the same as that of the other races, with the single exception of the vice of drunkenness. The Copts whom travellers usually meet are of the more respectable class, and hide their avarice under the mask of courtesy. They are more familiar and fluent than the Turkish effendis, and show in their intercourse none of that contempt for the infidel which the most polite Moslem can hardly refrain from manifesting. The domestic customs of the Coptic people differ but slightly from those of the Arabs of the Nile valley. There are some peculiarities, however, in their marriage ceremonies. The Copt bride, unlike the Moslem, has no canopy to cover her in the procession to the bridegroom's house; at the preliminary feast pigeons are released from pies and fly around the room shaking bells attached to their feet; in the church, besides the sacrament of communion, there is a ceremony of coronation, and the priest sets on the foreheads of the new couple a thin gilt diadem; the bride, in entering her husband's house, must step over the blood of a newly killed lamb; and the whole pageant, after lasting eight days, ends with a grand feast at the bridegroom's house. This is the custom with the wealthy and on the occasion of a young girl's marriage. The poor are wedded more simply, and no parade is made when a widow goes to the house of her second husband. All marriages, to be religiously lawful, must be licensed by the patriarch or bishop; but as civil contracts marriages licensed by the cadi are valid, and many of the poorer Copts prefer the disgrace of that resort to the extortion of their own spiritual rulers. Such marriages, moreover, are more easily dissolved than those which the priest solemnizes. The respectable Copt women live in the harem in seclusion. The wife's adultery is the only ground for divorce, notwithstanding that the incontinence of the husband is regarded as a sin. In most of the cities and large towns the Copts form but a fraction of the population. In the city of Cairo they have been estimated as high as 60,000; other writers put their number at 30,000, 20,000, or even 10,000. At Negaddeh, in Upper Egypt, there are 2,500; and Minieh, Osioot, Ekhmin, and Girgeh have each a considerable Coptic population. The whole race, from the sea to the Nubian frontier, number somewhat more than a 15th of the entire population of Egypt. In Nubia

they are not found.—The history of the Copts in Egypt, from the time of St. Mark to the Arabic conquest, is the history of the land itself. The names of their patriarchs, scholars, and anchorites, Clement, Origen, Athanasius, Cyril, Dionysius, Anthony, Macarius, and many more, belong to the annals of the Christian church, and are commemorated both in the Roman and Greek calendars. From the 3d to the 6th century Egypt had great influence in settling the doctrines of faith; its patriarch was the rival of the Roman bishop; its hermitages were the most attractive shrines of pilgrimage, and in its solitudes the persecuted believers found safety. From the latter half of the 5th century the controversy between the Melchite or royalist party, who adhered to the creed of the Greeks, and the Jacobite party, who were Eutychians, was vehemently maintained for more than a century, the victory inclining more and more to the Jacobite party. The pacific policy of Zeno for a time restrained open warfare; but in the succeeding reigns of Justin, Justinian, Phocas, and Heraclius the strife of arms was added to the strife of words, and bloody persecutions were carried on. In vain Apollinarius, at once prefect and patriarch, attempted by threatening and massacre to convert the Jacobite masses; roused by their zealous bishops, they returned defiance, and early in the 7th century all Christian faith not Monophysite was heresy from Alexandria to Syene. To quarrels with the Greeks succeeded quarrels with each other about minor points. Theodore and Themistius discussed the question concerning the wisdom of Jesus, the latter expressing the belief that Jesus was not omniscient. John the Grammarian affirmed that there were three Gods, and rejected the word unity from the doctrine of the being of God. In the five years of his administration as patriarch, from A. D. 611, John the Almsgiver made more converts by his zeal in good works than by his zeal against the Greek heresy; yet he was not acknowledged as a genuine patriarch, since he was appointed to office by the emperor, and followed the imperial party when it was driven from Alexandria by the invading Persians. In the ten years of Persian rule the patriarch was a true Copt. When the Romans regained power, the Jacobite Benjamin was displaced, and for a short time the church of Egypt had a ruler whose opinion was a compromise between the Greek and Jacobite views, maintaining two natures in Christ, but only a single will. In the great strife between the Greeks and the Arabs, which occupied the succeeding years, the Coptic church secretly inclined to the Moslem party, and it has been charged against them that their connivance with Amru and his army decided the contest in favor of the religion of the prophet. But if they were promised amnesty and protection, the promise was not long kept. Within a century from the fall of Alexandria the hands of monks were branded, and heavy annual imposts exacted of them, and such as refused to pay were scourged, outraged, and even beheaded; many of the churches, too, were destroyed and plundered. In the reign of the caliph Hashem (724–743), the Melchite dispute was revived by the restoration of some of the Greek bishops to their ancient sees in Nubia, and bribes by one and the other party swayed the authorities in either direction. In 755 it was forbidden to any Copt to hold any public office, even if he should embrace Islamism. In the time of the Abbasside dynasty the humiliations of the Copts were multiplied; the caliph Mutawackel compelled them to wear disgraceful articles of dress, and to fasten on their doors pictures of devils; and a century and a half later the mad Fatimite caliph Hakem prescribed for them the black robe and turban, ordered them to wear suspended from their necks a heavy wooden cross, confiscated their churches, and finally decreed their banishment. To save themselves from these heavy penalties great numbers apostatized, and in the following centuries the number of Christians steadily decreased. In 1301 an edict was issued requiring all Christians to wear blue turbans, and forbidding them to ride on horses or mules. Fresh conversions to Islam were the result of this edict. In 1321, by a bold conspiracy, the Moslem zealots destroyed simultaneously all the Egyptian churches, many of which were overturned from the foundations. The Christians retaliated by burning in Fostat and Cairo a large number of houses, palaces, and mosques. The punishment for these outrages, though it fell upon some of the Arabs, bore more severely upon the Christians. Some were hanged, some were burned alive, and leave was given to all Moslem subjects to rob and murder any Christian who might be seen wearing the white turban. No government official was permitted to employ a Copt. At the baths they were distinguished by a bell hung from the neck. Very numerous changes of faith resulted from this persecution, and at the end of the 14th century the condition of the Copts in numbers and influence had reached its lowest point, at which it continued with but little variation until the present century. Under Mehemet Ali and his successors, the Copts have had no occasion to complain of unreasonable taxation or of violated rights. Their exemption from military service, which seems to be a disgrace, is in reality a privilege, and is so regarded by most of their body.—A full statement of Coptic history may be found in vol. ii. of Quatremère's *Mémoires géographiques et historiques*. The most condensed account of their manners and customs is given in Lane's "Manners and Customs of the Modern Egyptians." Sir Gardner Wilkinson has given some valuable notices of the Copts in his work on Egypt, and Mr. Curzon has described the appearance and condition of their convents

and MSS. A good account of the Coptic versions may be found in the "Introductions to the New Testament" by Hug and Tregelles. Burckhardt, Bunsen, and Lepsius have furnished many important incidental notices, and the Arabic historian Makrizi has treated of the fortunes of the subject people in his elaborate account of their conquerors, and of Moslem rule in Egypt.

COPYRIGHT, a right conferred by law upon an author or his representatives to the exclusive sale or use of his intellectual productions. Owing probably to the circumstance that the ideas of property originated in an age of violence, the first laws recognizing property referred wholly to material things; and long before intellectual property acquired a pecuniary value, the laws of property in modern society were established, and it became difficult to admit a new object of property among those recognized by the ancient law. Since 1774 the law of England has been regarded as settled against the perpetual right of the author to his work, and the copyrights of authors in that country as well as in the United States are deemed property only by virtue of statute law. The copyright conferred by the statute applies only to works after publication. Before publication an author has the common law right of property in his manuscript, or other unpublished production. In England, by the act of 1842, copyright extends to 42 years, or for the life of the author and seven years thereafter, whichever period shall prove the longer. Protection is extended to books, maps, charts, pamphlets, magazines, engravings, prints, dramatic and musical compositions, paintings, drawings, photographs, sculpture, models, busts, and designs. Lecturers are also entitled to copyright on their lectures, and musical composers and dramatic authors may secure the sole right of performing their compositions or pieces for the term for which copyrights are granted. In order to secure a copyright an entry is made in the registry books at stationers' hall of the title of the work, the time of its publication, and the name and residence and interest of the proprietor or proprietors. A copy of every book is to be delivered within a month after publication to the British museum, and four copies at stationers' hall, for Oxford and Cambridge universities, the Edinburgh faculty of advocates, and Trinity college, Dublin. The first publication of the book must be within the realm; but such publication may be contemporaneous with publication abroad.— In the United States the authority over this subject is in congress. The act of 1870, which is a substitute for all previous statutes relating to copyright, permits any citizen or resident of the United States who shall be the author, inventor, designer, or proprietor of any book, map, chart, dramatic or musical composition, engraving, cut, print, or photograph or negative thereof, or of a painting, drawing, chromo, statue, or statuary, and of models and designs intended to be perfected as works of the fine arts, to secure a copyright thereof for 28 years, and gives a right to renewal for himself, his widow or children, for 14 years more; and authors may reserve the right to dramatize and translate their own works. The statute also gives to the author of a dramatic composition the sole liberty of publicly performing or representing it, or causing it to be performed or represented by others. A copy of the title of the book or other article, or a description of the painting, statue, &c., must be sent to the librarian of congress before publication, and two copies of the book, or in case of a painting, &c., a photograph of the same, must be sent to such librarian within ten days after publication. The librarian makes the proper record, receiving 50 cents therefor, and 50 cents for any copy, and there is also a small fee for recording and certifying assignments. A copy of any new edition is also to be sent to the librarian, and a penalty of $25 is imposed for any failure to forward such book, &c. The fact of the entry with the librarian is to be stated in each book or on each other article, and a failure to do this will preclude any action for infringement; while the publication of an entry not actually made subjects the party to a forfeiture of $100. Under previous statutes copyright was secured by depositing a printed copy of the title of the work in the office of the clerk of the district court in the district where the author or proprietor resided. The penalty for infringement of the copyright of a book is a forfeiture of the books printed, imported, &c., and such damage as a court may award; in case of maps, charts, prints, cuts, musical compositions, &c., a forfeiture of the plates, sheets, &c., and $1 for every sheet in possession of the guilty party; and in case of a painting, statue or statuary, $10 for every copy in possession; and in case of a dramatic composition, the damages which may be assessed, which shall not be less than $100 for the first and $50 for every subsequent representation. Authors are by the same law protected against the surreptitious publication of their manuscripts, and may recover damages therefor. In England ornamental and useful designs on articles of manufacture, &c., may be copyrighted; but in the United States designs come within the scope of the law concerning patents. It has been held both in England and America that newspapers are not protected by the copyright laws. Copyright is transferable to heirs and assignees. To entitle an author to copyright, his work must be original, and must not have been published or dedicated to the public prior to the application for copyright. Abandonment to the public before copyright renders the work common property, and defeats copyright. — Prior to 1845 the capacity of a foreign author to acquire, or at least to confer upon a British subject, valid copyright, does not seem to have been denied by the English courts. The ques-

tion was first thoroughly discussed in a court of law in that year, when it was held that a foreigner was entitled to the benefit of the statutes if he had given England the advantage of the first publication of his work. It was not till 1849 that the doctrine was absolutely announced by a court of law that a foreigner resident abroad could not acquire copyright in England or confer a valid title upon an English subject. After much change of opinion on this subject in the English courts, the question was decided by the house of lords in 1854, after an elaborate and exhaustive discussion in the case of Jefferys *v.* Boosey. The judges were nearly evenly divided in their opinions, but the judgment of the house of lords was that neither at common law nor by statute would English copyright vest in a foreign author while resident abroad. This uncertainty arose from the fact that the language of the statutes passed for the encouragement of learning, from the reign of Anne to the present time, has been general, extending protection to "authors," and leaving the courts to determine whether that expression included all authors or was limited to British authors. By this and other more recent decisions it has been settled in England that copyright will vest in any person, whether foreigner or citizen, upon three conditions: 1, publication must be in the United Kingdom; 2, there must have been no previous publication; 3, the author must have been at the time of publication within the British dominions. In the case of an English subject, however, presence within the realm is not necessary. When copyright has once vested, protection extends throughout the British dominions, including all parts of Great Britain and Ireland, and all the colonies, settlements, and possessions of the crown. It will thus be seen that the place of publication is limited to a less area than that throughout which protection extends, and within which the presence of the author at the time of publication is required. There may be a contemporaneous publication of the same work abroad, but a prior publication will defeat the copyright. A foreign author therefore may acquire a valid English copyright by first publishing in Great Britain, or publishing there on the day of publication elsewhere, if he be anywhere within the British dominions at the time of such publication. In order to meet this requirement of the law, it has not been uncommon for American authors to go to Canada and remain there during the publication of their work in England, thus acquiring a valid English copyright. In the United States, by the several copyright statutes that have been passed, from the act of 1790 to that of 1870, congress has expressly excluded foreigners from the benefits of copyright, extending protection only to such author as may be a "citizen of the United States, or resident therein." The judicial construction given to the word "resident" is that it refers to a person residing in the United States with the intention of making that country his place of permanent abode. A formal declaration of such intention is not necessary, nor is any definite period of time indicated as requisite to constitute such residence. The question is determined by the intention of the person at the time he has his abode here, and by his acts so far as they go to show what that intention was. If, at the time of recording his title in order to procure copyright, a foreign author is residing in the United States with the intention of making that country his place of permanent abode, he becomes a resident within the meaning of the act, and entitled to copyright without regard to the length of time of such residence, and notwithstanding the fact that he may subsequently return to his native country. On the other hand, if such author intends to remain temporarily, but actually remains for a long period, he is a mere sojourner, and does not acquire a residence so far as to be entitled to copyright. The assignee of a foreign author, though a citizen of the United States, holds the same relation under the statute as the author himself; so that a citizen is not entitled to copyright in a work which he has purchased from a foreign author. —In Great Britain provision is made for international copyright with such nations as may extend reciprocal protection to British authors. This is effected by an "order of her majesty in council," by which a foreign author resident abroad, by complying with the statute regulations as to registration, delivery of copies, &c., may secure protection for his work in Great Britain. In these cases it is not essential that first publication shall be in England. There are arrangements for international copyright with France, Prussia, Saxony, Hanover, Belgium, Spain, Italy, and other powers. An arrangement exists between England and France by which the author of a work published in either country may reserve to himself the exclusive right of translating such work for five years from the first publication of the translation authorized by him. No arrangement for international copyright has been entered into by the United States. The leading publishers in the United States are nevertheless accustomed to make a liberal allowance to British authors of established reputation from the profits on their books republished in this country. The difficulty of protecting British copyrights in the colonies has led to the laying of heavy duties for the benefit of their owners on reprints, copies, &c., imported.—In France and Belgium an author, and his widow after him, is entitled to a copyright for life, and the children for 20 years after; and in France the other heirs or assignees for 10 years, and in Belgium for 20 years after the death of the author or his widow. In Germany the copyright is for life and 30 years after. In Greece it is for 15 years from date of publication. In Russia copyright endures for life, and after the death

of the author passes to his heirs and assignees for 25 years, and for the further term of 10 years if they shall publish an edition within five years before the expiration of the first term.—Although there had been licensing acts prohibiting the publication of books without the consent of the owner, the first copyright act in England securing to authors the right of property in their works was the statute 8 Anne, chap. 19, passed in 1709. After reciting that "printers, booksellers, and other persons have of late frequently taken the liberty of printing, reprinting, and publishing, or causing to be printed, reprinted, and published, books and other writings without the consent of the authors or proprietors of such books and writings, to their very great detriment, and too often to the ruin of them and their families," it provided that after April 10, 1710, the authors of books already printed who had not transferred their rights, and the booksellers, &c., who had purchased copies, should have the sole right of printing them for 21 years; and that the authors of unpublished books and their assigns should have the sole right of printing the same for 14 years, at the expiration of which the sole right of printing or disposing of copies should return to the author, if living, for another term of 14 years. In 1769 a judgment was rendered by the court of king's bench, Lord Mansfield presiding, in the case of Miller *v.* Taylor, recognizing a perpetual property at common law in the author and his assigns. The work in controversy was "The Seasons," by James Thomson, the term of years secured by the statute of Anne having expired. This decision, however, was not long acquiesced in, and in 1774 the house of lords, in the case of Donaldson *v.* Beckett, declared against the common law right of property in books, although the weight of authority and numbers among the judges was in favor of the perpetuity at common law; and upon the question whether such right was taken away by the statute the judges were divided in opinion. In 1775 an act was passed by parliament which enabled the universities in England and Scotland and several colleges to hold in perpetuity their copyright in books given or bequeathed to them. In 1814 the term of copyright was fixed at 28 years, and during the life of the author if living at the expiration of that period. In 1833 the act 3 William IV., ch. 15, was passed, giving to the authors of dramatic compositions the sole right of representing their plays or causing them to be represented. This was followed by the international copyright act passed in 1838, giving a copyright in England to foreign authors whose governments had extended the same privilege to British authors. In 1842 the laws relating to copyright were revised, the term extended to the life of the author and for seven years after his death, or to 42 years from the first publication. This law, 5 and 6 Victoria, ch. 45, with some slight changes, still remains in force. The first copyright law in the United States was passed in 1790. The term for books then published was 14 years, and for unpublished books the same period with provision for renewal for 14 years. In 1831 a general copyright law was passed granting copyright for 28 years, and providing, for a renewed term of 14 years. In 1856 an act was passed giving to authors the exclusive right of publicly representing or causing to be represented their dramatic compositions. In 1870 all the statutes relating to copyright were repealed by the general copyright law which is now in force.

COQUEREL. I. Athanase Laurent Charles, a French Protestant clergyman, born in Paris, Aug. 27, 1795, died there, Jan. 10, 1868. He studied at the divinity school of Montauban, and was ordained in 1816. The next year he was invited to become pastor of the Episcopal chapel of St. Paul in the island of Jersey, but was unwilling to subscribe to the thirty-nine articles. After preaching for 12 years to the Walloon congregations at Amsterdam, Leyden, and Utrecht, he was in 1830 invited to Paris by Cuvier, then minister of Protestant worship, and succeeded M. Marron as pastor in the Reformed church; and in 1833 he became a member of the consistory. He was a very successful preacher, and was also much interested in the subjects of education, and from 1831 to 1848 lectured on religion in the school of St. Victor, afterward the Chaptal college. For defending the university against a determined attack, he was rewarded in 1835 with the decoration of the legion of honor. In 1841 he was appointed Protestant chaplain of the collége Henri IV. From 1831 to 1833 he edited the *Protestant*, a religious, political, and literary journal, and from 1834 to 1836, in conjunction with M. Artaud, the *Libre Examen*. In 1841, with the help of some pastors of like views, he started the *Lien*, of which he was for a time the principal editor, and which he relinquished in 1844 to his brother, and subsequently to his sons. He took a prominent part in the discussions called forth by a religious revival which prevailed in England, Switzerland, and the Protestant churches in France, opposing the supporters of the movement, and declaring his opposition to the old Calvinistic theology, the doctrines of predestination, eternal punishment, and expiation, although he maintained against the German rationalism the inspiration of the Scriptures and the doctrine of the fall. He was opposed in the ministry of public worship, as well as by the evangelical school of Protestants, and in 1835 was refused settlement in a chapel at Batignolles which he had been mainly instrumental in founding. His reputation and popularity grew in spite of opposition, and in 1848 and 1849 he was elected a member of the constituent and legislative assemblies, where he acted with the moderate republican party. After the *coup d'état* of Dec. 2, 1851, he retired from political life, and devoted himself wholly to religious work. In 1853 he

joined in the organization of the *Alliance chrétienne universelle*, which was designed to unite on a common basis the members of the Greek, Latin, and Protestant churches. Since 1852 M. Coquerel had been one of the central council of the Reformed churches, and in 1867 became its president by seniority. In this position he urged his colleagues to concede something to liberal views, but without success. He wrote 700 or 800 sermons, of which a great number have been printed, forming 8 vols. Besides these his principal works are: *Biographie sacrée* (1837); *Histoire sainte et analyse de la Bible* (1838 and 1842); a reply to Strauss's "Life of Jesus" (1841; *Orthodoxie moderne* (1842); *Le Christianisme expérimentale* (1847); *Christologie, ou Essai sur la personne et l'œuvre de Jésus-Christ* (1858); *Méditations sur des textes choisies de l'Ancien et du Nouveau Testament* (1859); *Observations pratiques sur la prédication* (1860); and *Projet de discipline pour les Églises réformées de France* (1861). Many of his works have passed through several editions, and been translated into English and other languages. **II. Charles Augustin,** a French author, brother of the preceding, born in Paris, April 17, 1797, died there, Feb. 1, 1851. He was brought up with his brother by their aunt Helena Maria Williams, an English authoress, at whose house he met Humboldt and other celebrated men. He studied at the divinity school of Montauban, but in 1815 went to Paris and devoted himself to general science and literature, studying medicine under Broussais, chemistry under Gay-Lussac, mathematics under Ampère and Biot, and astronomy under Arago. In 1821 he published the *Annuaire protestant*, the earliest work of the kind in France. He was one of the founders of the *Revue Britannique* (1825), and contributed also to the *Revue protestante*. Among his published works are: *Caritéas* (1827); *Histoire de la littérature anglaise*, and *Essai sur l'histoire générale du Christianisme* (1828); and *Histoire des Églises du désert*, his most important work, a record of the sufferings of the French Protestants since the revocation of the edict of Nantes. **III. Athanase Josué,** son of Athanase Laurent Charles, born June 16, 1820, died in July, 1875. He studied theology at Geneva and Strasburg, was ordained to the ministry at Nîmes in 1843, and became assistant pastor in that city. In 1848 he was appointed Protestant chaplain of the collége Henri IV., and subsequently of the Chaptal college, a post which he held for 20 years. On Nov. 15, 1850, although opposed by orthodox leaders, he was appointed by the consistory of Paris an assistant pastor, and was reappointed in spite of increasing opposition in 1853, 1856, 1859, and 1861. Having succeeded to his father's position as editor of the *Lien* and afterward of the *Nouvelle Revue de Théologie*, he published in the *Lien* the constitution of the newly formed liberal Protestant union, and in 1863 an appreciative though qualified notice of Renan's "Life of Jesus." In consequence of this he was at length, Feb. 26, 1864, suspended from the ministry by the consistory of Paris, while the consistory of Anduze voted him an address of sympathy. In 1867 he gave a series of lectures against the doctrinal authority of the Apostles' creed. In 1871 he visited the United States, and lectured during the winter in several cities. He received the decoration of the legion of honor in 1862. Besides many pamphlets, sermons, and articles, he has published *Des beaux arts en Italie, au point de vue religieux* (1857); *Jean Calas*, a historical study (1858); *Précis de l'histoire de l'Église réformée de Paris* (1862); *Des premières transformations historiques du Christianisme, Pourquoi la France n'est elle pas protestante?* and *Les forçats pour la foi*, a sketch of the Protestants condemned to the galleys by Louis XIV. and Louis XV. (1866); *La conscience et la foi* (1867); and *Libres études* (1868).

COQUILLA NUTS, the fruit of the Brazilian tree *attalea funifera* (Martius) or *cocos lapidea* (Gärtner). The nuts are nearly solid shells, commonly containing two small kernels of disagreeable flavor. They are valued only for the solid portion of the shell, which is of very close texture, brittle and hard, and of a hazel-brown color. It is susceptible of a high polish, works well in the lathe, and is an excellent material for small ornamental works, as toys, heads of umbrellas, parasols, &c.

Coquilla Nut and Palm.

COQUIMBO. I. A N. province of Chili, lying between lat. 29° and 32° S., and lon. 69° 30′ and 71° 35′ W., bounded N. by Atacama, E. by the Argentine Republic, S. by Aconcagua, and W. by the Pacific; area, 13,300 sq. m.; pop. in 1870, 159,698. The surface is mountainous, but there is only one volcano within its limits, that of Limari. The Chuapa, on its S. boundary, the Illapel, Coquimbo, Barrazo, and Tongoy, are the principal streams, all of which are small and from the rapidity of their

descent unnavigable. The banks of most of them are high and steep, and they can be crossed only by means of hanging bridges of rope. The climate is healthy and delightful, and the soil, where capable of cultivation, is productive. Fruit is abundant, especially figs and grapes, but not enough grain is raised for consumption. The province is rich in minerals, particularly in silver and copper. Gold, lead, and quicksilver are also found. The copper mines are numerous and extensively worked. The chief industry is the smelting of this metal, which is carried on to such an extent that much ore is imported from the north of Chili and from Bolivia, in addition to what is mined in the district. Its ports are Coquimbo, Guayacan, Tongoy, and Totoralillo. **II.** The capital of the province, also called La Serena, on the river Coquimbo, not far from its mouth, 255 m. N. N. W. of Santiago; lat. 29° 54′ S., lon. 71° 16′ W.; pop. about 15,000. The city is regularly built, with streets generally at right angles, and in the S. part there is a large plaza. The houses, which are mostly of one story, stand apart surrounded by gardens. Among the principal buildings are several churches and convents, a public school, and a hospital. It has also water and gas works. It is a bishop's see.—The town was founded in 1542, by Francisco de Aguirre, who called it La Serena from his native town in Spain. The port of Coquimbo, which is several miles distant on the bay, is one of the best harbors of Chili. It is spacious and safe in all seasons, and, notwithstanding the scarcity of wood and water, is much frequented. The exports are chiefly copper in bars, ingots, regulus, and ores, some silver and cobalt, and hides. The imports are mostly coal, mining materials, and provisions.

CORAL (Gr. *κοράλλιον*; Lat. *coralium*, *curalium*, or *corallum*). The derivation and use of this term are discussed by Theophrastus in his work on plants. Such were these stony products of the ocean naturally believed to be, from their growth resembling that of the productions of the garden. Imitating the forms of trees and flowering shrubs, they rivalled them in gracefulness and delicacy; and the brilliant hues of the blossoms that crowned them made permanently beautiful these gardens in the depths of the sea. And when at last Peysonnel, in an elaborate memoir sent to the royal society in 1751, supported the opinion (first advanced by the Neapolitan naturalist Ferrante Imperato in 1599) that the coral blossoms, *les fleurs du corail* (so described in 1706 by Marsigli), belonged to the animal and not to the vegetable kingdom, his views met with a cool reception among naturalists, and were pronounced even by Réaumur too absurd to be discussed. The power of vegetation to produce stately forests and the minutest plants was familiar to naturalists. To ascribe still greater power and as elaborate skill to "poor, helpless, jelly-like animals," seemed like an insulting demand upon their credulity. The controversy was continued through the greater part of the last century. The coral animals were shown in form resembling blossoms, sending forth their petal-like tentacles in series around the mouth, and drawing into this their prey. Still Linnæus would admit their possession only of a nature intermediate between plants and animals, and the word zoöphyte (Gr. *ζῶον*, animal, and *φύειν*, to grow like a plant) was applied by him to the organic bodies, with reference to their supposed relation to both kingdoms. The word is still in use with naturalists as a distinctive term for the division of animals in which the sponges are included. The whole compound animal mass produced by budding is called by Prof. J. D. Dana a zoöthome (Gr. *ζῶον*, animal, and *θωμός*, a heap), and the single animal is called by him a polyp.—Coral is the stony frame which belongs to these animals, as a skeleton belongs to an individual of the higher orders of the animal kingdom. It is called by Prof. Dana the corallum, and the coral of a single polyp in the mass is called a corallet. It is formed within the

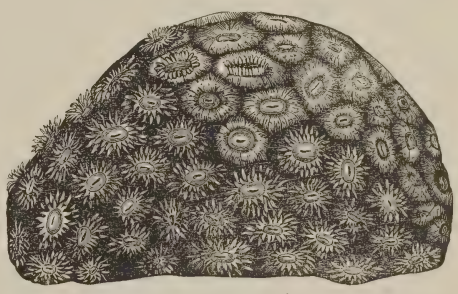

Fig. 1.—Coral Animals (Astræa pallida).

mass of them by animal secretion, each individual adding to the common structure, not by actual effort directed to this purpose, but by the involuntary secretion of calcareous matter. Hence it will be seen that corals are not, as formerly supposed, the products of the labor of the coral animals, but are the results of a growth analogous to that of the bones in other animals. A single polyp of the genus *astræa* (see fig. 1), for instance, has a disk above surrounded with tentacles, like the actinia or sea anemone, to which it is closely allied; the mouth at the centre of the disk opens into a stomach, and is the passage for the food and for the exit of refuse matters. Below and around the stomach space is divided radiately by a series of pairs of fleshy plates, the larger of which extend from the stomach to the sides of the polyp. The coral is secreted between the plates of these several pairs, as well as through the tissues; and hence comes the radiate character of the interior of the cells over the surface of a coral, that is, the star-like interior of each corallet. The material of the coral is carbonate of lime, or the same that constitutes limestone, and it is taken by the polyp from the sea water or from its

food. Fig. 2 represents the coral of a single polyp, one of the larger simple kinds, reduced to one fourth its natural size. When alive the whole corallum was concealed by the fleshy

Fig. 2.—Fungia echinata.

exterior; the mouth was situated over the middle portion of the median furrow from which the calcareous plates radiate outward; and these radiating calcareous plates of the coral were secreted between pairs of fleshy plates, as stated above. Fig. 3 represents one of the branching corals; in the living state each little prominence was the interior of a separate flower-like polyp.—Coral polyps, besides producing eggs and young like other animals, generally multiply also through a process of budding which is closely like growth by buds in the vegetable kingdom. A new polyp commences as a mere prominence on the side of an old one; soon the mouth and tentacles appear; then both continue growing, each adding to the calcareous accumulation within,

Fig. 3.—Branching Coral.

and each sending forth new buds to be developed into new polyps. According to the manner in which the buds develop the mass receives its shape. In some species they branch out into tree-like forms from the buds putting forth laterally. In many species of the madrepore family each branch terminates in what is called the parent polyp, this terminal polyp continuing to grow on and at the same time making new polyps for the sides of the branch by the process of budding. In a few species of other kinds each polyp forms a separate branch, at the termination of which it is seated; at these extremities the growth goes on, while the stem below is left behind dead. Other species, in which the polyps form massive corals, put forth the young polyps in the spaces which are produced between the older ones as these extend upward, or they make new ones by a subdividing of an old polyp; thus keeping the hemispherical form symmetrical, till in a single astræa dome a diameter of even 12 ft. has been attained, and the polyps, each occupying a square half inch only, have increased to more than 100,000 in number. Many polyps are of still smaller dimensions. A porite of the same size should con-

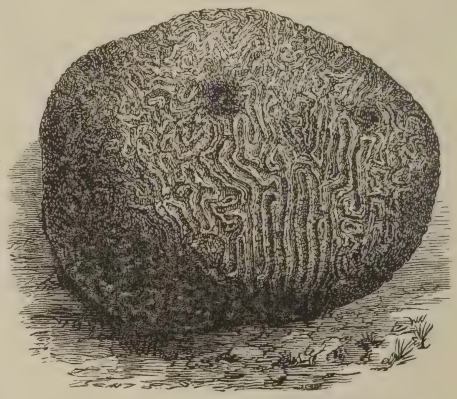

Fig. 4.—Meandrina (Diploria) cerebriformis.

tain, according to Prof. Dana, more than 5,500,000 individuals. The genus is often met with over the coral reefs, in rudely shaped hillocks sometimes measuring 20 ft. across. Fig. 4 represents a kind, related to the astræas, called brain coral, in allusion to the meandering furrows over the surface. Here, instead of each polyp having a separate cell with its mouth over the centre of it, there are a large number of polyps coalesced along a single furrow, many mouths being visible in the living meandrina along the bottom of the furrow, and a row of tentacles along either side. In addition to the hemispherical forms seen in the star coral (*astræa*) and the brain coral (*meandrina*), and the madrepore shrubs and trees, Prof. Dana remarks that "some species grow up in the form of large leaves rolled around one another like an open cabbage, and cabbage coral would be no inapt designation for such species. Another foliated kind consists of leaves more crisped and of more delicate structure, irregularly grouped; lettuce coral

would be a significant name. Each leaf has a surface covered with polyp flowers, and was formed by the growth and secretion of these polyps. Clustered leaves of the acanthus and oak are at once called to mind by other species; a sprouting asparagus bed by others. The mushroom is here imitated in very many of its fantastic shapes, and other fungi, with mosses and lichens, add to the variety. Vases of madrepores are common about the reefs of the Pacific; they stand on a cylindrical base, which is enveloped in flowers when alive, and consist of a network of branches and branchlets, spreading gracefully from the centre, covered above with crowded sprigs of tinted polyps. The actiniæ may well be called the asters, carnations, and anemones of the submarine garden; the tubipores and alcyonia form literally its pink beds; the gorgoniæ and melitæas are its flowering twigs; the madrepores its plants and shrubbery; and astræas often form domes amid the grove a dozen feet or more in diameter, embellished with green or purple blossoms which stud the surface like gems, while other hemispheres of meandrina appear as if enveloped in a network of flowering vines." Over the surface of all these corals each depression is the site of a polyp; and the radiated form of this cell corresponds in its plates to the similar structure of the animal. As young polyps are produced, they communicate for a time or permanently with the parent stock, through the internal cavity, in some species each having in the early period of growth nothing externally to mark its separate existence but a new mouth and incipient tentacles. In a living polyp, the tentacles are expanded and made rigid by injection with sea water. When disturbed, the water is ejected, the tentacles contract and disappear beneath the margin of the disk which is rolled inward over them, and conceals also the mouth. In many even of the larger corals the living portion is but a thin outer part of the mass, the rest having become dead by the drying up of the tissues as growth went on. The various forms of coral are produced by as many species of polyps. A large number of kinds are described and figured by Prof. Dana in his great work "On Zoöphytes," and a general review of the subject, illustrated by many figures, is given in his "Coral and Coral Islands" (New York, 1872).—Among the tribes of corals, some species or other are found in all oceans from the equator to the polar regions, and to the lowest depths explored by man. But the range of individual species and families is limited by the physical conditions of light, heat, pressure, &c., appropriate to their organization. Those tribes which produce the great coral reefs, as the astræas, madrepores, meandrinas, &c., are developed with peculiar luxuriance in the warmest parts of the Pacific, where the temperature varies from 75° to 85°; but they are also found in waters the temperature of which during the coldest winter months does not fall below 68°, and in other oceans and seas. Two isothermal lines of 68°, one N., the other S. of the equator, near the parallel of 28°, but varying therefrom according to the marine currents and the vicinity of continents, will include all the growing coral reefs of the world. The higher the temperature, the greater is the profusion and variety of the coral reefs. The range in depth of the reef-forming corals appears to be limited to 120 ft., and comparatively few are found below half that depth. This statement may at first sight seem inconsistent with the fact that coral is often found extending from a few feet to hundreds and even thousands of feet below the surface of the sea. Various theories have been advanced to account for this, but they have all been rejected, and the explanation first offered by Mr. Darwin is now very generally adopted by the scientific world. Mention has already been made in the article Atoll of the coral reefs of the Pacific, where they are traced in barriers for hundreds of miles; and also of the annular form of many of them, the reef surrounding shallow basins, while the waters outside are often of unfathomable depth. According to Mr. Darwin's theory, which is supported and more fully developed by Prof. Dana in his recent work above mentioned, the bottom of the ocean where these atolls are found has been for ages slowly subsiding, while the coral reef has *pari passu* been growing upward. Hence, while the living coral has never existed more than 50 or 100 ft. below the surface of the water, the coral rock, the product of former ages, exists at immeasurable depths. The dead corals and shells of the coral seas become ground up by the waves as they sweep over the reef, and thus the beds of coral débris are made which become by consolidation the coral reef rock. This reef rock differs in no important particular from the great limestone strata which are spread over large portions of the western states, and which testify by the corals they contain, and the other fossils associated with them, to a similar mode of production. The fine white mud which is made by trituration much resembles when dried the ordinary white chalk of Europe. It is often spread over the bottoms of the lagoons or channels, and is also drifted over the shallow seas outside of the reefs by currents. Throughout the long series of the geological formations produced by aqueous deposition, back to those of the Silurian era, the agency of the marine polyps is traced in the production of limestones. At one period, in the lower Devonians, there were true coral reefs of great extent over the Mississippi basin, and along the northern borders of New England; and the corals of those old reefs may be now seen making the old reef rock at the falls on the Ohio near Louisville, and near Lake Memphremagog, in northern Vermont. Unmistakable coral rocks of recent production are met with in the islands of the Pacific and Indian oceans, sometimes hundreds

of feet above the level of the sea. In the tertiary and cretaceous formations ranging along our own coast, corals of various species, as perfect as specimens brought from the East Indies, are occasionally taken from the marl pits, together with multitudes of shells, such as now belong to warmer latitudes. Teeth of sharks and of other fishes are scattered with the shells throughout the rocks of these districts, precisely as they are now left by the fishes whose remains lie entangled among the reefs which were their pastures. Most fossiliferous groups thus contain in their calcareous strata evidences that corals have contributed more or less to their origin. Even limestones that are now crystalline and without a trace of a fossil (owing to alteration through the action of heat and other metamorphic agencies) are in some cases, largely of coral formation. Thus part of the material of the solid marbles quarried from the midst of granitic rocks, and apparently as far removed in their origin as these from the agency of organic bodies, are traced back to the digestive and secretory operations of the coral polyps. By analyses of different varieties of coral, they are found to consist almost solely of carbonate of lime (95 to 98 per cent.). There is a small proportion, usually from 1½ to 4 per cent., of animal matter, and according to Sharples 0·27 to 0·90 per cent. of phosphate of lime. Prof. B. Silliman found fluorine in some corals, and Sharples the "slightest traces of it." Forchhammer obtained 2·1 per cent. of magnesia from the precious coral of the Mediterranean, and 6·36 per cent. from an Isis. The soluble salts of sodium, which form the greater part of the solid matters contained in sea water, are rejected by the polyps, and only those materials are made use of which are best fitted for producing the most substantial structures. By their removal, the waters of the ocean are kept of uniform composition. The soluble impurities poured into them by every river, but for some such provision, would accumulate, as the fresh water alone is carried off by evaporation. The coral insects and marine shells are the agents appointed to keep pure the waters of the great deep, to take up and store away the excess of the lime salts, and preserve the balance in this department of nature, as the vegetable growth performs a similar office in keeping down the excess of carbonic acid in the atmosphere. The great ocean currents spread all the waters among the coral groves, as the winds convey the air through the forests. The mightiest forces of nature are thus made to administer food to the tiny polyp and the other life of the coral reef.—The coral which is used in jewelry is known as precious coral (*corallum rubrum*). It is mostly obtained in the Mediterranean, the Barbary coast furnishing the dark red, Sardinia the yellow or salmon color, and the coast of Italy the rose-pink; in Europe and in this country the latter is most valued, while in the East the dark red is preferred. Torre del Greco, near Naples, is the residence of many of the coral fishers, and the place from which boats are fitted out for the business. The coral obtained by them is sold to the merchants of Naples, who have it manufactured into various articles of ornament for the European market.

CORAM, Thomas, an English philanthropist, born about 1668, died March 29, 1751. He spent the early part of his life as a sea captain. Having seen in the poorer parts of London many children abandoned and cruelly exposed, he projected the foundling hospital, in which design he labored 17 years, and at last procured a royal charter and a grant of £10,000 from parliament. He was also instrumental in promoting American trade by procuring a bounty on naval stores from the colonies, and by interesting himself in the settlement of Georgia and Nova Scotia. He died while perfecting a scheme for the education of Indian girls. An annuity of £100 was raised for him by subscription in his old age.

CORATO, a town of S. Italy, in the province and 25 m. N. W. of the city of Bari; pop. in 1871, 26,220. It contains a fine collegiate church, several convents, and an orphan asylum, and carries on a considerable trade in olives. It was founded by the Normans in the 11th century.

CORAY, Adamantios, a Greek author, born in Smyrna, in April, 1748, died in Paris, April 6, 1833. Educated a merchant, he was also an ardent student of the ancient and modern languages, in which he became deeply learned. While yet a young man he was intrusted with the care of a branch of his father's mercantile house in Holland, and remained in Amsterdam six years, allowing himself no recreation from business, except two lessons a week in mathematics and philosophy. He returned to Smyrna in 1779, a few days after a fire had destroyed the warehouses and residence of his father. He then renounced commerce, and for six years devoted himself to the study of medicine at Montpellier in France. His parents dying in poverty a year after he left Smyrna, he was obliged to support himself by translating English and German medical works into French. He went to Paris in May, 1788, and resolving to aid in the liberation and regeneration of his country, he wrote a number of political tracts, and published in a series called the "Greek Library" a variety of ancient Greek works, with notes and translations, calculated to excite the patriotism of his countrymen; among the most celebrated of which were the editions of the Ethics and Politics of Aristotle. He was employed in a translation of the geography of Strabo by Napoleon, who conferred on him a pension.

CORBAN, a Hebrew word occurring in the Greek of the New Testament (Mark vii. 11), where it is translated a "gift." It designates an oblation to God, and has reference to a formula of consecration, by using which, under

pretence of dedicating anything as his property to God, a person might prohibit the use of it to his parents or to any party to whom it was thus made corban. Property so dedicated went into the treasury of the temple and the keeping of the Pharisees, who held that when the formula was once spoken, even if in anger, the speaker was relieved of any duty to aid another with what he had so devoted.

CORBAUX, Fanny, an English artist and Biblical scholar, born in 1812. When she was about 15 years of age her father suddenly became reduced to poverty, and, without having received any but the most superficial instructions in drawing, she determined to support herself and him by painting. So severe and well directed were her labors, that in the same year she received two silver medals for water-color drawings, and within the next three years another silver medal and the gold medal of the society of arts. She had been all the time her own instructor. After that she painted small pictures in oil and water colors, but has confined herself chiefly to portraits. She was one of the first to assert the right of women to obtain admission as students to the royal academy. As a Biblical scholar she has written a valuable series of letters on "The Physical Geography of the Exodus," and another entitled "The Rephaim."

CORBEIL, a town of France, in the department of Seine-et-Oise, on both banks of the Seine at its confluence with the Essonne, 17 m. S. by E. of Paris; pop. in 1866, 5,541. It contains many flour mills, an immense granary of seven stories built in 1762 for the supply of Paris, and a fine grain market of iron, built in 1862. There are stone bridges across the Seine and the Essonne. The church of St. Spire, rebuilt in 1437 after a fire, having been first built in 950 by Haymon, first count of Corbeil, contains the tomb of Jacques de Bourgoin, founder of the college of Corbeil; and the little church of St. Jean de l'Île was built by the templars in the 13th century. Just outside the town there is a hospital founded in 1864 by the Messrs. Galignani. Corbeil has manufactures of shawls, cashmeres, printed goods, woollen yarn, earthenware, and plaster.

CORBET, Richard, an English poet and divine, born at Ewell, Surrey, in 1582, died in 1635. He was educated at Westminster school and at Christchurch college, Oxford, of which he became dean in 1620. He was much esteemed for his eccentric wit and generous spirit, was made chaplain to James I., bishop of Oxford in 1629, and of Norwich in 1632. His poems, written early in life, were published after his death under the title of *Poetica Stromata* (1647). A fourth edition, with his life, was published in London in 1809.

CORBOULD. I. Henry, an English artist, born in London, Aug. 13, 1787, died there, Dec. 9, 1844. He was considered one of the most accomplished draughtsmen of his time, and devoted nearly his whole life to drawing from ancient marbles in the possession of various private collectors, and of the British museum. The collection in the latter institution occupied him nearly 30 years, and his drawings were in the course of publication at the time of his death. He was also a frequent and graceful designer for illustrated books. **II. Edward Henry,** an English painter, son of the preceding, born in London, Dec. 5, 1815. He early manifested a taste for art, and between 1835 and 1837 gained gold medals awarded by the society of arts for his "Fall of Phaëthon from the Chariot of the Sun," "St. George and the Dragon," and "Chariot Race between Atrides and Antilochus." Soon afterward he was elected a member of the new society of painters in water colors. Some of his earliest pieces, exhibited at the royal academy and elsewhere, illustrated subjects from Spenser's "Faerie Queen." His first large picture was "The Canterbury Pilgrims at the Tabard Inn in the Borough of Southwark," which was followed by a number illustrating scenes from English history and kindred subjects. In 1842 his "Woman taken in Adultery" was purchased by the prince consort for Queen Victoria. In 1851 he was appointed teacher of drawing to the royal family. He paints exclusively in water colors, confining himself chiefly to figure subjects, and is noted for spirited composition and a peculiar richness of coloring. His picture from Tennyson's "Morte d'Arthur" is esteemed his best work. He excels in pageants and chivalric subjects. He has also painted scenes from the opera and the drama, including portraits of Garcia, Mario, Grisi, and Charles Kean.

CORCYRA. See Corfu.

CORDARA, Giulio Cesare, an Italian Jesuit, born in Alessandria in 1704, died there in 1790. He was the second son of the count of Calamandrana, entered the society of Jesus in his 14th year, and, after teaching in the colleges of Viterbo, Fermo, and Ancona, was appointed professor in the Roman college. In 1742 he was chosen historiographer of his order, and in 1750 published a continuation of the history of the society of Jesus by Orlandini, Sacchini, and Jouvency (2 vols. fol.). On the suppression of the Jesuits he retired to his native city, where he continued to cultivate poetry and letters. His works, which also comprise a history of the foundation of Nice, of the Germanic and Hungarian colleges in Rome, and of Prince Charles Edward's expedition to Scotland, were published in Venice in 1805, in 4 vols. 4to.

CORDAY D'ARMANS, Mariane Charlotte de, a French heroine, born at St. Saturnin des Lignerets, in the present department of Orne, July 28, 1768, guillotined in Paris, July 17, 1793. Her father was a poor Norman nobleman of literary tastes, and author of works of a republican tendency. Her mother died during her early youth; her two brothers entered the army; one of her sisters died young, and she and her remaining sister were placed by

their father in a convent at Caen. Among the visitors was M. de Belzunce, a young cavalry officer, between whom and Charlotte a tender feeling sprung up. She was intellectual, vehement, and enthusiastic; she was a republican in feeling, and entertained the most exalted ideas of the duties of patriotism. Her lover having been assassinated by the mob of Caen, she vowed revenge against those whom she conceived to have instigated the murder. After the revolution had closed the doors of the convent, she removed to the house of her aunt, an old royalist lady. Many Girondists had fled to Caen; among them was Barbaroux, and Charlotte found a pretext for calling upon him. The conversation chiefly turned upon the tragic fate of the Girondists, upon Mme. Roland, and upon Marat, for whom she had long felt a horror. On the morning of July 9, 1793, she suddenly left the house of her aunt, on pretext of a journey to England. On the 11th she was in Paris, where she took a room not far from Marat's dwelling. For a time her mind was undecided as to whether Marat or Robespierre should fall, when Marat's journal, *L'Ami du Peuple*, in which he said that 200,000 more heads must be lopped off in order to secure the success of the revolution, fixed her determination. She addressed a letter to Marat soliciting an audience, in order to acquaint him with the plots of the Girondists at Caen. No answer came, and on the morning of July 13, after having purchased a knife in the Palais Royal, she called upon Marat, who then resided in a gloomy house in the rue des Cordelières. She was refused admittance. She wrote a second note and called again at half-past 7 the same evening, when with some difficulty she gained admittance to Marat, who was just taking a bath. He listened to her report of the proceedings of the Girondists, and taking down their names, remarked with a smile, "Within a week they will all go to the guillotine." Drawing the knife which she had concealed in her bosom, she plunged it to the hilt in Marat's heart. He gave a loud cry and sank back dead. She was immediately arrested and transferred to the nearest prison, the Abbaye. Her trial took place on the morning of July 17; she was sentenced to death, and guillotined the evening of the same day. Her courage did not forsake her for a moment. She declared that her project had been formed since May 31, when the Robespierre party had pronounced the doom of the Girondists, and that she had killed one man in order to save a hundred thousand. Her remarkable beauty and her lofty bearing on her way to the guillotine sent a thrill even through the hearts of her executioners. A young German enthusiast, Adam Lux, a deputy from the city of Mentz, at the execution cried out, "She is greater than Brutus." He wrote a pamphlet suggesting that a statue with such an inscription should be erected to her memory, for which he was arrested and guillotined. André Chénier, who paid a glowing poetical homage to her heroism, shared the same fate a year later.

CORDELIERS. **I.** A name given in France to the friars of the Franciscan order, in allusion to the cord tied with three knots which they wear as a girdle. The title is said to have originated in the time of the crusades, when St. Louis, struck by their prowess in battle with the infidels, asked their name, and was told that they were *cordeliez*, or "tied with cords." At one time there were in France 224 male and 123 female convents of this order. (See FRANCISCANS.) **II.** A political club during the first French revolution, which received the name from its members meeting in the chapel of the old convent of the Franciscan friars situated near the rue de l'École de Médecine and the rue de l'Observance, in the centre of the quarter of Paris known as the Cordeliers' district. It became the focus of the wildest agitators, and was constantly quarrelling with the Jacobin club. Marat and Danton were its ruling spirits. At the time the club was in its zenith, Camille Desmoulins edited a popular journal in connection with it under the name of *Le vieux Cordelier*. The club was closed by the law of 6th Fructidor, or Aug. 23, 1795, which dissolved all the political clubs of France.

CORDILLERA, a Spanish word meaning a mountain chain or ridge. It is commonly applied to the whole or a portion of the chain of the Andes, as *la Cordillera de los Andes; la Cordillera de la Costa*, the chain which runs near the Pacific coast; and *la Cordillera Real*, the northern prolongation in Venezuela and Colombia of the main interior chain. Some authorities consider the Cordilleras of Central America and those extending northward near the Pacific to the frigid zone as the continuation of the Andes, forming with them one range from the Antarctic to the Arctic ocean, and that hence they should be described under one common name. But the break at the isthmus of Panama, the only one in the chain between this point and the straits of Magellan, the diverging course of the ranges of the Andes as they approach the northern limits of South America, and the fact that the comparatively low elevation of the isthmus can at the most be called the continuation of the inferior Cordillera of the coast, taking on the other side of the break an entirely new course, as it sweeps round to N. W.—these lead others to the conclusion that the mountain ranges of North and South America are too distinct from each other to be classed as one range, notwithstanding they are connected by the continuation throughout their extent of the same great geological formations. The South American Cordilleras have been treated under the title ANDES; the ranges through Central America and Mexico may be described under the present head; while to their extension further north the name ROCKY MOUNTAINS is given.—Upon the isthmus the Cordilleras present the lowest and narrowest

barrier between the two oceans. The distance across varies from 30 to 70 m. The railroad constructed from Aspinwall on the Atlantic side to Panama on the Pacific coast traverses the isthmus in a length of 48 m., ascending to the summit level only 300 ft. It is said that the summit level between Port Escoces on the Atlantic and the mouth of the Savanna in the harbor of Darien is only 150 ft. above the sea, and this point is suggested as the most favorable for a ship canal between the two oceans. Yet the mountains, as seen from the sea, present the appearance of continuous ranges of great height, the overlapping of the ridges concealing the gaps, the valleys and low lands, and the thickly wooded plains that lie between the mountains. The unhealthiness of this portion, the incessant rains that fall during a considerable part of the year, the almost impenetrable nature of its forests, and the inhospitable disposition of the Indians that occupy the territory, have prevented its resources from being developed. These ridges present steep slopes toward the Pacific; on the Atlantic side they fall away more gently. The San Juan river finds its way through them from Lake Nicaragua to the Atlantic, the main range, called the Alto Grande, continuing to the N. E. of this lake and of the adjacent smaller lake, Managua. On the other side a straight and narrow mountainous belt separates these lakes from the Pacific, which belt is so unbroken that, though the waters of the lakes and the ocean approach within 12 m. of each other, and a stage road passes across from Rivas to San Juan del Sur, yet no favorable route appears to exist for the construction of a ship canal, even if the rapids of the San Juan in its passage through the Cordilleras were so improved as to form a part of the interoceanic communication. Along this western range occur several volcanoes and many extinct craters and beds of lava, though the real volcanic belt lies a little further east, passing through the western portion of the two lakes. The central basin between the two outer mountain ranges, including the two lakes, and extending about 300 m. in length by about 150 in width, comprises the fine state of Nicaragua, a country presenting the greatest diversity of beautiful scenery. The rugged mountains on each side are the frames in which are included the broad fertile plains and the large lakes, one of which extends in a parallel direction with the mountains a distance of about 100 m. From its surface and on its shore huge volcanoes rise abruptly to the height of several thousand feet; others appear ranged along the same line, disturbing the smooth contour of the vast plains, above which they stand dark and gloomy, their sides rent with the deep volcanic fissures and black with their covering of ancient lavas. The shores of the lakes are covered with the dense vegetation of the tropics, while the broad slopes of the Alto Grande overlooking them are the open grazing lands for countless herds of cattle. Beyond these, along the summits of the great range, and upon the sources of the streams which flow into the Atlantic, is the mineral region of Chontales, Matagalpa, and Segovia, extending further northward into Honduras. The geological formations of the western portion of the basin appear to be almost wholly of a volcanic character, as basaltic rocks and lava, with limestone and a calcareous breccia formed in great part of volcanic products. The volcanoes still emit smoke and sometimes flame from their summits, but streams of lava are rarely known to flow from them. Some of the larger, as that of Momobacho (about 5,000 ft. high) on Lake Nicaragua, a few miles S. of the city of Granada, are regarded as extinct. The volcanic cone of Ometepec, upon an island in the same lake, is very regularly shaped, and, like the neighboring summit of Madeira, rises to a greater height than Momobacho. The volcanoes El Viejo and Momotombo, N. W. of Lake Managua, are about 6,000 ft. high. The climate of this portion of the Cordilleras is salubrious and of moderate temperature, cooled by the trade winds after these have shed a considerable portion of the moisture they come charged with from the Atlantic upon the easternmost ridges of the range. The rains are therefore not excessive even during the rainy season, which extends from May to November. The thermometer during this season rarely sinks by night so low as 70° upon the plains, or rises in the day to 90°. In the dry season the temperature is somewhat lower, and the nights are cool, especially upon the mountains.

—Through Honduras, San Salvador, and Guatemala the Cordilleras continue with little variation of character. On the east they send out spurs toward the Atlantic, and the inferior volcanic range still skirts the Pacific. Five volcanoes are enumerated in San Salvador, the most active of which is Yzalco, and the two highest, San Vicente and San Salvador, are each estimated to rise to an elevation of about 7,500 ft. In Guatemala six volcanoes are in activity, viz.: Pacaya, Fuego, Agua (which pours forth torrents of water), estimated to be about 14,000 ft. high, Atitlan, 12,500 ft., Sapotitlan and Amilpas, 13,000 ft. Earthquakes are frequent throughout this region. Upon the main range of the mountains, in the department of Tegucigalpa in Honduras, at the source of the Patuca or Patook, which flows into the Atlantic, it is stated that 40 silver mines are found within a circuit of 30 miles radius; but from want of enterprise in the inhabitants they are worked to little advantage. Near the Pacific coast copper ores are found abundantly, but they too are neglected. They are also met with in the Lepaguare valley in the department of Olancho, and were formerly worked to supply the mint at Tegucigalpa, the ores being carried eight days' journey upon the backs of mules. These regions produce in great abundance valuable mahogany, rosewood, red cedar, boxwood, India rubber, vanilla, cochineal, sarsaparilla,

&c., large quantities of most of which are floated down the Patuca to the Atlantic coast. The temperature of the interior region is never excessive; the thermometer during the dry season from November to February seldom rises above 80° F. at noon, or falls below 55° in the morning. During the summer wet months at Jutecalpa, considerably to the eastward of the main range and below its summits, the nights are said to be always cool, and the extreme temperature of the day is below 95°.—Passing from Guatemala into Mexico, the mountain ranges diminish in height. At the isthmus of Tehuantepec one may pass from ocean to ocean over a summit not more than 700 ft. high. The mountains thence to the northern limits of the state spread out in a vast plateau, the height of which along its middle portion is from 6,000 to 8,000 ft. above the sea, and its greatest width near the latitude of the city of Mexico is about 360 m. It extends N. W. at this elevation full 600 m., presenting a smooth surface, mostly unsheltered by the growth of forest trees, though the soil is naturally fertile. Still further N. for 900 m. the plateau is traced at an elevation of from 2,000 to 3,000 ft. On either side one descends from this cool elevated region by successive steps to lower plateaus, each descent bringing the traveller into a region of warmer temperature and of more tropical productions. From the *tierra fria*, or cold region, the first descent is to the *tierra templada*, or temperate tract; the next to the *tierra caliente*, the low lands along the coasts, hot and unhealthy. So steep are the walls of these plateaus, that for a distance of 500 m. only two roads passable by carriages lead from the Atlantic coast into the interior—one passing from Vera Cruz through Jalapa, and the other by Saltillo west of Monterey. On the western side the descent is hardly less precipitous, and to the south the great plateau ends abruptly near the shores of the Pacific. The climate of the plateau, though called cold, is said not to differ in its mean temperature (which is about 62° F.) from that of the central parts of Italy. There are some still more elevated tracts, as the valley of Toluca, about 8,500 ft. above the sea, where the thermometer during a great part of the day rarely rises beyond 45° F. The volcanic mountains, which are still met with along the chain as far as lat. 24° N., rise from the great plateau in stupendous masses, and penetrate with their lofty peaks the limits of perpetual snow. Their range is not, as in the more southern states, near to and parallel with the Pacific coast, but a line of them appears to cross that of the great mountain chain in an E. and W. direction, passing about 16 m. S. of the city of Mexico. The most western of them, Colima, stands alone upon the plain of the same name, situated between the plateau and the Pacific. Its height is about 12,000 ft. Smoke and ashes are frequently thrown from its crater, and an eruption began in 1869 in which vast quantities of pumice stone were ejected. Jorullo, upon the western slope of the plateau, 70 m. from the Pacific, is described by Humboldt as suddenly appearing above the surface in the night of Sept. 28 and 29, 1759, after a succession of earthquakes, accompanied by constant subterranean noises, which had continued for about three months. A tract covering several square miles rose above the plain to the height of 524 ft. Flames burst forth from all parts of this area, and burning rocks were thrown with vast clouds of ashes into the air, the softened surface of the earth rising and falling like the waves of the sea. Rivers of water flowing into the chasms caused eruptions of mud to issue from thousands of little cones that appeared upon the surface. In the midst six mountain masses were suddenly formed along a chasm ranging from N. N. E. to S. S. W. The principal one of them is the great volcano of Jorullo. Its height above the sea is 4,265 ft.; that of the plain upon which it stands is 2,890 ft. Its great eruptions continued till the month of February, 1760; subsequently they became less frequent. A wall of basalt forms the boundary of the upheaved tract, which in most places, especially on the western side, is too steep to be ascended. The celebrated valley of Mexico, nearly 7,500 ft. above the sea, and covering an area of 18 leagues in length by 12½ in breadth, is encircled by groups of mountains, among which are the famous volcanic peaks of Popocatepetl, Iztaccihuatl, and Toluca. The first rises to the height of 17,720 ft. above the sea, and 500 ft. above the termination of vegetation. Its crater is 3 m. in circumference and 1,000 ft. deep, and is in continual eruption. The second is an extinct volcano 15,705 ft. high. A chain of small volcanoes connects these with each other, and with the other volcanoes further east. The Cofre de Perote lies between Popocatepetl and the fiery Orizaba, or Citlaltepetl, "the mountain of the star," so named for the fires that ever issue from its snow-enveloped summit, dispelling as by the light of a brilliant constellation the darkness of the night through the surrounding country. Orizaba, as measured by Ferrer in 1796, is 17,879 ft. high; but later calculations by Humboldt and others reduce these figures somewhat. It is generally thought that Popocatepetl is the higher of the two, and consequently the highest peak in Mexico. Below the plateau, in the region of low hills near the gulf of Mexico, is Tuxtla, the last of the volcanoes upon this line, a few miles west of Vera Cruz. It was in operation in 1793, when the ashes thrown from its crater were carried as far as Perote, a distance of 57 leagues. The great Mexican plateau, though a considerable portion of it is as level apparently as the ocean itself, is cleft by fissures called *barrancas*, two or three miles in length, and often 1,000 ft. deep. A brook or small river flows at the bottom, the banks of which are the precipitous and rugged walls of the chasm.

Some mountain ranges besides those of the volcanoes rise above the plain, as one bordering it on the eastern side, and the Sierra Madre, which, commencing at lat. 21° N., and extending 60 m. further north, separates it for this distance into two portions. Other ridges here unite with it, spreading out into the mountainous district of Zacatecas, celebrated for its rich silver mines. Beyond this the Sierra Madre forms a belt of full 100 m. in breadth of parallel ridges and valleys extending to New Mexico, where it unites in lat. 33° N. with the southern portion of the Rocky mountains. Between the Rio Colorado and the Rio Grande del Norte, some of the summits of the Sierra Madre exceed 10,000 ft. in height above the sea, and are continually covered with snow. The geological structure of the Cordillera of Mexico is that of granitic and volcanic rocks, together with the micaceous, talcose, and clay slates, which form a considerable portion of the range, especially in the mining districts. So many of the rich silver mines of Mexico are found in porphyry, that its presence is regarded as particularly favorable for the existence of this metal. It is also found, however, in the metamorphic limestones, and in those called by Humboldt the Alpine and the Jura. In no part of the range of the Cordilleras in North and South America has the production of this metal been so great as in Mexico. It was estimated by Humboldt to be ten times as great as that furnished by all Europe, and two thirds of the whole production of the globe. The vegetation of the elevated country varies with its height. On the high plains the forests destroyed by the early Spanish settlers have never been renewed, though there are still to be seen fine open groves of gigantic oaks and pines, clear of undergrowth. The plains as seen about the city of Mexico are not always fertile, but are covered in many places with saline incrustations.

Prison of the Inquisition.

CORDOVA (Span. *Córdoba*). **I.** A S. province of Spain, in Andalusia, bounded N. W. by Badajoz, N. by Ciudad Real, E. by Jaen, S. E. by Granada, S. by Malaga, and S. W. and W. by Seville; area, 5,190 sq. m.; pop. in 1867, 379,464 (estimated). The Sierra de los Pedroches, a range of the Sierra Morena, crosses from E. to W. the part of the province N. of the Guadalquivir, which is generally mountainous. The Guadalquivir flows from E. N. E. to W. S. W. across the province, receiving from the north the Rio de las Yeguas, Cuzna, Guadiato, and Bembezar, and from the south the Guadajoz. From the Guadalquivir southward stretches a fertile plain, the Campiña, to where the Sierra de Priego occupies a small tract of country in the extreme south. The province is somewhat deficient in water, but produces grain enough for its own use, and great quantities of wine, oil, hemp, flax, saffron, honey, and wax. Fine mules and horses are bred, and bees, game, fish, cattle, and swine are plentiful. There are numerous mines of coal, copper, iron, silver, and lead, and manufactures of silk, woollens, and pottery. The principal towns are Cordova, Baena, Cabra, Castro del Rio, Fuente Ovejuna, Lucena, Montilla, Montoro, and Rambla. **II.** A city (anc. *Corduba*), capital of the province, in lat. 37° 52′ 15″ N., lon. 4° 49′ 37″ W., 70 m. N. E. of Seville, situated in a beautiful plain on the right bank of the Guadalquivir, here crossed by a Moorish bridge of 16 arches; pop. in 1867, 41,976. It is renowned for its picturesque buildings, its beautiful location on the southern declivity of the Sierra de Cordova, and its unsurpassed cathedral, once a Moorish mosque. The town itself resembles eastern towns in its inconveniently narrow streets, and its want of ventilation and cleanliness. It is enclosed by high walls flanked by square, round, and octagonal towers, built by the Moors on the foundations of the old Roman line of circumvallation. There are several churches and religious houses, a bishop's palace, a theatre, a museum, a lyceum, a *plaza de toros*, and several hospitals. The great mosque was founded by Abderrahman I., A. D. 786. It was an edifice of marvellous beauty, with a light, elegant roof, springing from clusters of slender pillars, and was lighted with 4,000 silver lamps. There were originally 1,200 pillars, but 400 have been taken away to make an open space suitable for Christian worship.

Cordova was once celebrated for its manufactures of leather, but this industry was transferred by the Moors to Morocco. Its silversmiths and filigree workers are still cele-

The Great Mosque (now Cathedral).

brated.—Corduba was the birthplace of the two Senecas and of Lucan the poet. It sided with the sons of Pompey, and after the battle of Munda it was taken by Cæsar, when 23,000 of its inhabitants are said to have been put to death. Its foundation is attributed to Marcellus, the commander in the Celtiberian war (152 B. C.), and being peopled by poor patricians of Rome, it was hence called *Colonia Patricia*. Under the Goths it was called the "holy and learned." Osius, the friend of St. Athanasius and the counsellor of Constantine, was its bishop from the end of the 3d to the middle of the 4th century. Under the Moors Cordova became a great centre of learning and power; produced Averroes, Maimonides, and other famous scholars; rose to be the capital of the Moorish empire of Spain, and the seat of the caliphate from 756 to 1031, eclipsing Bagdad by its splendor, and containing in the 10th century nearly 1,000,000 inhabitants, 300 mosques, and 900 baths. After the overthrow of the caliphate, Cordova passed into the hands of various rulers. In 1236 it was conquered and almost wholly destroyed by Ferdinand III. of Castile, a blow from which it never recovered. In 1808 it was taken and pillaged by the French under Dupont.

CORDOVA. **I.** A central province of the Argentine Republic, lying between lat. 29° and 34° 15′ S., and lon. 61° and 66° 15′ W., bounded S. by the Pampas; area, 60,000 sq. m.; pop. in 1869, 208,771. The E. and S. parts are barren and almost uninhabited, but the remainder is generally fertile. Near the W. border is the mountain range called the Sierra de Cordova, running N. W. and S. E. It separates into two branches and ramifies through the central parts of the province, but has no very lofty peaks, the highest, La Cuesta, rising about 2,500 ft. above the plain. Numerous rivers, the principal of which are the Primero, Segundo, Tercero, Cuarto, and Quinto, descend from this chain, but the most of them are lost in the sandy plains. Only one, the Tercero, finds its way into the Paraná, under the name of Carcarañia. The sierras abound in copper ore, but little has been done to develop the mines. Near the mountains the country is covered with dense forests, mostly of trees of the mimosa variety. The valleys are fertile, but the people are engaged generally in cattle and sheep raising, and pay little attention to agriculture. The plains, irrigated by the mountain streams, furnish abundant pasturage, and are frequented by vast herds of the guanaco. Wheat and the sugar cane grow to perfection, but scarcely enough is raised for home consumption. Hides and wool, the latter of very superior quality, are almost the only exports. Besides Cordova, the capital, there are no towns of any consequence. **II.** The capital of the province, situated on the right bank of the river Primero, in lat. 31° 24′ S., lon. 64° 9′ W., 375 m. N. W. of Buenos Ayres, on a plain 1,240 ft. above the level of the Paraná at Rosario; pop. in 1869, 28,523. It is laid out in straight, narrow streets, intersecting at right angles, forming squares of 150 yards each. The better houses are of stone, one story in height, and built around paved courts into which all the rooms open. The Alameda, a square of about 150 yards, has a miniature lake and fine trees. The principal public buildings are the cathedral, a handsome structure in the renaissance style, several other churches, three monasteries, and a nunnery; the university, occupying the buildings of the old Jesuit college, which was for more than a century the principal seat of learning in La Plata; the Argentine national observatory, not yet (1873) entirely completed, though in successful operation, under the charge of Mr. B. A. Gould; the *cabildo* or government house, an orphan asylum, and an infirmary. The city, once the ecclesiastical metropolis of South America, still retains much of its former character, and the clergy and their connections form the most influential part of society. Its trade is important, as all the traffic of the W. and N. W. provinces passes through it to the east. The exports are chiefly hides and wool, and the imports manufactured goods. The city was founded in 1573 by Don Luis de Cabrera, with the design of opening a route from Peru to the Paraná. It is now connected with the latter at Rosario by a railway, about 215 m. long.

CORDOVA, a city of Mexico, in the state and 57 m. W. S. W. of the city of Vera Cruz, at the foot of the volcano of Orizaba; pop. about 6,500. It is regularly built, with broad well paved streets, and a fine square in the centre, having Gothic arcades on three sides, and a fountain in the middle. The cathedral, a very handsome edifice, with a richly decorated in-

terior, occupies the fourth side. Its houses are mostly built of stone. The soil of the surrounding country is rich, and the climate being moist and warm, it is very productive. Tobacco, coffee, and sugar are raised and exported in large quantities, and cotton, woollen goods, and leather are manufactured.

CORDOVA, Fernando Fernandez de, a Spanish general, born in Madrid in 1792. He entered the military service in 1810, and was rapidly promoted during the war with Napoleon. In 1841 he was implicated with Gen. Concha in the movement instigated by O'Donnell against Espartero. In 1847 he was a short time minister of war, and was appointed inspector general of infantry. Two years afterward he was sent to Gaeta in Italy at the head of an army to aid in the restoration of the pope. On March 8, 1850, he was appointed captain general of New Castile, in the following year of Cuba, and in 1853 general-in-chief of the cavalry. Immediately after the outbreak of the revolution of 1854, he was called upon by Queen Isabella to form a new cabinet. This he declined, but he ordered his soldiers to fire upon the insurgents, and when the latter proved victorious he fled to France. In 1856 he returned to Spain, and in 1864 was made minister of war in the cabinet of Narvaez.

CORDOVA, Francisco Fernandez de, a Spanish navigator, born in the latter part of the 15th century, died in Cuba in 1518. He commanded a small expedition which sailed from Havana in 1517, discovered Yucatan, where he had several encounters with the natives, and touched at Florida on his return. His report led to the expedition of Juan de Grijalva, who received the credit of the discovery.

CORDOVA, Gonsalvo de. See GONSALVO DE CORDOVA.

COREA, a kingdom on the E. coast of Asia, bounded N. by Mantchooria, N. E. by the Russian Amoor country, E. by the sea of Japan, S. by the strait of Corea, and W. by the Yellow sea and the Chinese province of Liaotung, and lying between lat. 34° 25′ and 43° N., and lon. 124° and 130° 30′ E.; area, 90,000 sq. m. The population has been variously estimated from 8,000,000 to 20,000,000. No accounts of the geography or constitution of the Corean kingdom are in existence, and only the barest notion of the internal configuration of the country has been arrived at. It comprises a peninsula 400 m. long and 140 m. wide, most of the adjacent islands, especially numerous on the W. coast, and a part of the main continent. Its length from N. to S. is 660 m. It is separated from Mantchooria by the Shangpeshan mountains, and the Chimtai range follows the E. coast along its whole extent. Nearly all the principal rivers run W. down the larger watershed which slopes from the Chimtai to the Yellow sea. The largest is the Yalu in the northwest, which is deep and rapid, and navigable for large ships 22 miles. South of this are the Tatong and the Han. On other watersheds are the Falu, which flows from the Chimtai into the strait of Corea, and the Tumen, a large river in the northeast which flows into the sea of Japan. The coast, which is generally high and rocky, is particularly abrupt on the E. side. On this side there are few islands except in lat. 39° 45′ N., in Broughton's bay. In the strait of Corea there are many islands, and between lat. 34° and 35° N., on the W. side, are the Amherst isles and the Corean archipelago. These coast islands are seldom more than three or four miles long, are rocky and high, but generally inhabited. The island of Quelpaert, 60 m. S. of the peninsula, is about 60 m. in circumference, and on it is Mt. Auckland, 6,558 ft. high. The climate is cold, especially in the north, where the Tumen is frozen for six months in the year, and barley is the only grain which can be raised. In the southwest, where the climate is more temperate, the soil is more fertile than elsewhere. The country produces wheat, rice, millet, cotton, hemp, ginseng, and fruits. Tobacco and cotton are cultivated to some extent. The orange, citron, hazlenut, pear, chestnut, peach, mulberry, and wild grape are common. Cattle, a breed of diminutive horses, hogs, and many domestic animals common to Europe, are raised. The keeping of sheep, however, is said to be prohibited by the government. In the forests of the coast and mountainous districts of the north bears, wildcats, panthers, deer, and the sable and other fur-bearing animals are found. The royal tiger is a native of the country, and has a longer and closer fur than in Bengal. Gold, silver, iron, and salt are said to abound, but mining is restricted by the government to its own requirements. Coal is also said to exist.—The inhabitants are of the Mongolian race, of larger size than the Chinese, resembling the Japanese, but with features more prominently Mongolian

Coreans.

in type. In dress, architecture, and social life they much resemble the Chinese, with the exception of being the only people in eastern Asia with whom the ancient caste distinctions are still rigidly in force. They do not cut off their hair, nor are their women kept under such restraint as in China. The language differs widely from both Chinese and Japanese, but it is like the latter in its polysyllabic form, and its alphabet of 27 letters. The higher classes are well educated, use the Chinese characters in writing, and are followers of Confucius. The mass of the people are Buddhists. Roman Catholic missionaries have been laboring in Corea since 1632, and in 1857 there were 15,200 converts. On account of the strict laws against them, the missionaries work in secret. The Coreans oppose not only the introduction of Christianity, but of all foreign civilization and commerce. The only intercourse allowed with China is officially confined to two points, viz., Peking, which is annually visited by an envoy accompanied by a few privileged traders, and the "gate town" near the city of Funghwang in Liaotung, on the frontier dividing the two countries, where a fair is periodically held. But the Chinese manage secretly to carry on trade at the islands on the coasts of Corea. The principal manufactures are silk, cotton, cotton paper, grass cloth, rice paper, arms, and horsehair caps; which articles, with ginseng, skins, gold, silver, iron, rice, and oil, are the chief exports. The principal trade is with Japan, from which are imported pepper, aromatic woods, horns, and European and Japanese manufactured goods.—The government is despotic, and as regards the mass of the people is unrestrained; but powerful parties among the nobles appear to exercise a certain control over the king's actions, and decide questions of disputed succession, which frequently arise. Absolute power over the lives and property of the people seems to be in the hands of even the lowest officials, and frightful flagellations are often inflicted by their order on persons guilty only of trifling offences. The king pays tribute to China and Japan. The ministry is divided into five departments, and the country into eight *taos* or administrative districts. Over each tao is a governor responsible to the king. These taos are subdivided into 41 *koons*, with 33 towns of the first class, 38 of the second, and 70 of the third. Kienghi-tao, or Hanching, or Wangking as the Chinese call it, literally royal capital (called by the French Séoul), the capital, is at a short distance inland on the river Han. The other principal towns are Kieng, Tsien, Piengyang on the Tatong river, and Hienhing on Broughton's bay. The whole population is liable to military service, but no standing army is maintained, unless it be a guard to the king. They know accordingly nothing of military discipline and tactics. The people take turns in doing duty as armed police, and while serving in that capacity wear a rounded top to the crown of their hat. They have spears, bows, and a kind of matchlocks, which, in spite of their primitive description, exhibit a very workmanlike finish. The guards are furnished with an armor of chain mail, which was found in the recent encounter with the United States naval force to be proof against sword cuts and musket balls, but not against rifle shots; it was however so heavy, a single suit with helmet weighing about 20 pounds, that the troops were rendered almost incapable of locomotion. The Coreans live in the most frugal manner, and articles of daily necessity to the Chinese and Japanese are unknown among them. They do not drink tea, and their most palatable beverage is the water in which rice or millet has been boiled. The wealthy indulge in an infusion of ginseng, and in a kind of rough spirit distilled from various grains. The universal material for clothing is a coarse white fabric of cotton or hemp. The lower classes wear in summer jackets and wide short trousers; the higher classes wear over a vest and trousers a long gown with buttons in front, and sometimes dyed of a blue color. Every Corean carries a belt with a tobacco pouch and a pipe, a long stem of bamboo. Officials wear upon their hats the figures of different birds or animals, and a variety of small balls of amber or silver, securing the chin strap above the ear. Military officials denote their rank by an outer jacket of colored silks.—Corea was known from a very early period to the Chinese, who claim that it was civilized by their sovereign Khil-su in 1120 B. C. In the 13th century the Mongol conquerors incorporated the greater part of Corea with the Chinese empire; but in the 14th century the founder of the Ming dynasty acknowledged the claimant of the Corean throne, and conferred upon him the title of feudatory king, or Kao-li Wang, which designation is the origin of our word Corea (Fr. *Corée*), obtained from the Japanese, who represent the Chinese sound as Ku-rai. The Coreans were conquered by the Japanese in 1592, but in 1598, with the aid of the Chinese, compelled their conquerors to abandon the country. In 1866 a French expedition escaladed Kanghoa, a town on the Han, 40 m. from its mouth, and endeavored to obtain satisfaction from the Corean government for the murder of two Roman Catholic bishops and seven priests who had been put to death by order of the ministry; but the town was found to be wholly deserted. The Coreans sent to the French some professions of desiring to negotiate with them, but were only bent on gaining time for the purpose of overwhelming the handful of invaders. The French found themselves one day confronted by about 500 soldiers, who discharged on them a heavy fire, wounding 32 men and 3 officers. Admiral Roze had to embark his forces, and returning to Chefoo found that the French government would not support this hasty action, inaugurated by the ambassador at Peking. In the

same year an American trading ship, the General Sherman, ascended the Piengyang river, and was destroyed with all on board, in obedience to orders from the regent, while lying dry on the shore, having departed from the proper channel during a period of floods. In 1871 a United States squadron under Admiral Rodgers sailed to Corea from Nagasaki, advanced up the river Han, and began to survey the river and forts in the direction of the capital. While thus occupied they were fired upon from the forts, and as a punishment for this action the Americans on June 11 captured and destroyed several of their river fortifications. Being unable however to open negotiations with the king, Admiral Rodgers released the prisoners whom he had taken. (See supplement.)

CORENTYN, a river of South America, which rises in the Sierra Acaray, flows generally N., forming for its whole length the dividing line between British and Dutch Guiana, and enters the Atlantic by an estuary about 25 m. wide at its mouth. Sir R. Schomburgk ascended it in 1836 as far as lat. 4° 21′ 30″ N., lon. 57° 35′ 30″ W., 150 m. from its mouth, where is a series of cataracts 900 yards across, beyond which it is only navigated by small vessels.

CORFU. I. A nomarchy of the kingdom of Greece, comprising the islands of Corfu, Paxo, Leucadia, and several smaller islands; area, 427 sq. m.; pop. in 1870, 96,940. **II.** One of the Ionian islands (anc. *Corcyra*), lying between lat. 39° 21′ and 39° 51′ N., and lon. 19° 36′ and 20° 8′ E., off the S. part of the coast of Albania, from which it is separated by an irregular channel from 1 to 20 m. in width; length from N. W. to S. E., 40 m.; greatest breadth, 20 m.; area, 227 sq. m.; pop. in 1871, 75,466. From the north it tapers gradually to its S. extremity, where it ends in Cape Branco. The surface is mountainous, especially in the north, where Mt. Pantocratoras rises to upward of 3,000 ft. The high lands are rugged and bare, but the valleys are very fertile and watered by small streams, which in summer are mostly dry. The climate is mild, the annual range of the thermometer being from 31° to 88°, but with sudden changes. Earthquakes are frequent. The principal products are olive oil, of which the yield in ordinary seasons is about 200,000 barrels, wheat, maize, oats, wine, cotton, flax, oranges, citrons, salt, honey, and wax. The island is divided into three eparchies, Corfu, Oros, and Mesi, and sends 12 members to the legislative assembly of Greece. —Corfu is believed to be the Homeric Scheria, the domain of King Alcinous. About 734 B. C. it was colonized by the Corinthians, and soon after it became a leading maritime power, and a formidable rival of Corinth. In 665 the Corcyrean fleet vanquished one sent against it by the mother city, and this engagement is said by

Corfu—View of Town and Citadel.

Thucydides to be the first naval battle on record. In the Persian wars the Corcyreans, according to Herodotus, betrayed the national cause, and subsequently by calling in the aid of Athens against Corinth kindled the Peloponnesian war, during the progress of which they lost their power and importance through the ruinous struggles of the democratic and oligarchical factions. In 229 B. C. the island fell into the hands of the Romans. It afterward belonged successively to the Eastern empire, the Normans, and the Venetians, and in 1797 was occupied by the French. Two years later it was taken by the Russians and Turks, subsequently united with the other Ionian islands, ceded to France, and captured by the English. With the rest of the Ionian islands it was placed under the protection of Great Britain by the congress of Vienna, but was ceded to Greece in 1864. A Greek garrison took possession on May 28 of that year. **III.** A city, capital of the nomarchy, situated on the E. coast of the island, 5 m. from the coast of Albania, and 212 m. N. W. of Athens; pop. in 1871, 15,452. It consists of two parts, the town and citadel, and has several suburbs. The citadel is built upon a rocky point projecting into the sea, and between it and the town is an es-

planade laid out with avenues and trees, and containing a statue of Count Schulenburg, who defended the city for the Venetians against the Turks in 1716. The citadel contains the barracks, arsenal, hospital, the former residence of the British commissioner, now occupied by the Greek government, and a lighthouse. There are two other fortresses, Fort Neuf, at the west end of the town, and Vido on a small island 1 m. distant. The streets are Italian in style, some having arcades like those of Padua and Bologna, but are irregular, and the houses are small. There are a cathedral, several ancient churches, a university, gymnasium, ecclesiastical seminary, and other schools. The town is supplied with water brought in pipes a distance of 7 m. It is the residence of a Greek archbishop and of a Catholic bishop. It communicates with Otranto in Italy by weekly packets, and with Trieste, Athens, Gibraltar, and England by steamers sailing twice a month; and is connected with Otranto and with Malta by submarine telegraphs. It was the capital of the Ionian republic.

CORIANDER, the fruit of *coriandrum sativum*, an annual umbelliferous plant. It is a native of Italy, but now grows wild in most parts of Europe, and is brought from thence to the United States. The flowers emit a disagreeable odor when bruised, but the fruit has a pleasant fragrance. The fruits, or seeds as they are called, are about an eighth of an inch in diameter and globular in shape. They have an aromatic odor and taste. Their virtue depends on a volatile oil, which is obtained by distillation. Coriander is used in medicine only to correct the action and cover the taste of other drugs, and render them acceptable to the stomach. It may be given in the dose of half a drachm or more. Confectioners use it as a flavoring article.

Coriander.

CORIGLIANO, a town of S. Italy, in the province and 26 m. N. E. of the city of Cosenza, situated near the mouth of a river of the same name; pop. about 13,000. It is poorly built, and the streets are narrow. It contains an aqueduct, five churches, six convents, and a few public buildings. Licorice is made here on a large scale, and there is considerable trade in timber, wine, oranges, lemons, and olives. The best manna of Calabria is produced in the neighborhood. On an eminence overlooking the town is a feudal castle with massive towers and a deep trench. Near by is the site of the ancient city of Sybaris, famed for the voluptuousness of its inhabitants.

CORINTH, a city of ancient Greece, in the Peloponnesus, 48 m. W. of Athens, near the S. W. extremity of the isthmus which connects that peninsula with central Hellas, and separates the Corinthian and Saronic gulfs. It was situated some distance from each coast, at the foot of the Acrocorinthus, and in the centre of the Corinthia, a subject territory extending around the city on every side, but of very limited extent, bounded N. by the Corinthian gulf, N. E. by Megaris, E. by the Saronic gulf, S. by Argolis, and W. by Sicyonia. It was in most parts mountainous and barren; the rocky sides of the Geranean range on the north, the sandy plain of the isthmus, and the rugged Onean hills offered no reward for the labors of the husbandman. The plain N. W. of the city, extending along the coast in the direction of Sicyon, was, however, so fertile and valuable for market gardening, that to possess "what lies between Corinth and Sicyon" became a proverbial expression for great wealth. The most striking natural feature in the Corinthia was the Acrocorinthus, the acropolis of Corinth. This is a rocky isolated hill rising abruptly to the height of 1,886 ft., and is in natural defences the strongest mountain fortress of Europe. At the N. base of this stood the ancient city, which was 5 m. in circumference, though its entire perimeter, enclosing the Acrocorinthus, was upward of 10 m. It had two excellent port towns, viz.: Lechæum on the gulf of Corinth, with which it was connected by means of two parallel walls, and Cenchreæ on the Saronic gulf. Of the topography of the city as it existed in the flourishing periods of Grecian history we are comparatively ignorant. Of the Roman city afterward built upon its ruins we have the account of Pausanias, who visited it in the 2d century of our era. He describes many fine buildings and other monuments of the former magnificence of the city. In the port Lechæum he specifies the temple of Neptune and a brazen statue of that god, and at Cenchreæ a temple of Venus and a stone statue. He describes the agora or forum as surrounded by temples and adorned with columns and statues. In this stood the statues of Bacchus and of Diana of the Ephesians; here too was the temple of Fortune, with its statue of Parian marble; here the temple dedicated to all the gods, adjoining which was a fountain surmounted by a brazen Neptune. Near by stood statues of Apollo

Clarius and of Venus; also two of Mercury and three of Jupiter; while conspicuous among them all, in the very centre of the agora, stood a Minerva of bronze on a pedestal adorned with a beautiful bass-relief of the muses. North of the agora was the Propylæa, surmounted by two gilded cars, the one bearing Phaëthon, the other the sun. Beyond stood a brazen Hercules, near which was the fountain Pirene, celebrated for the salubrity of its waters, which issued from artificial caverns, and were collected in an open marble basin. From this fountain Pindar characterizes Corinth as the "city of Pirene;" and the Delphic oracle, according to Herodotus, speaks of the Corinthians as "those who dwell around the beautiful Pirene." The ascent to the citadel was lined on either side with temples and altars, nine of which are mentioned by Pausanias; while on the summit itself stood the famed temple of Venus, to which goddess the entire Acrocorinthus was especially consecrated. In the days of Corinthian luxury and opulence, this shrine is said to have been attended by 1,000 female slaves, who were kept for the use of strangers visiting the city. On the street which led from the agora to Sicyon stood the temple of Apollo, some traces of which still remain in the N. W. outskirts of the modern town. Corinth is now a small town, whose inhabitants carry on a little trade in dried fruits, wheat, and oil, which they export from a port in the bay of Corinth. A concession was granted in 1873 to Theodore Turbini, a banker of Athens, for cutting a canal through the isthmus of Corinth, to be completed in 1879.

—The earliest rulers of Corinth are represented as Æolians, though a large proportion of the population were no doubt Ionians. The reputed founder of the ancient dynasty was Sisyphus. Under him and his descendants the city is represented to have been very prosperous, and to have grown in wealth and power. Thucydides says that the Dorians, when invading the Peloponnesus, took possession of the hill Solygia, near the Saronic gulf, from which they carried

Corinth.

on war against the Æolian inhabitants of Corinth, till they reduced the city. Aletes, their leader, became the first Dorian king, and the founder of a dynasty, which, continuing through 12 generations, according to tradition, ruled upward of 300 years. During this period Corinth, though thus ruled by Dorian kings, and regarded as a Dorian city, did not by any means conform to all the severe institutions of the Dorians; the commercial connections and importance of the city, the luxury and wealth which a vast foreign trade introduced, exerted a powerful influence upon the fortunes of the state. About 747 B. C. the powerful Dorian family known as the Bacchiadæ succeeded in abolishing royalty, and in electing one of their own number as annual prytanis, or president. Thus was established an oligarchy which lasted till about 657, when it was overthrown by Cypselus. Under the Bacchiads Corinth was already distinguished for commercial enterprise, wealth, and power; and at this time Syracuse and Corcyra were colonized by the Corinthians. It was probably under them also that the first navy of triremes, or war galleys, was launched upon the Grecian waters. Thucydides expressly assures us that the Corinthians were the first of the Greeks to use triremes or galleys with three banks of oars. Cypselus established a new dynasty, which for 74 years ruled Corinth with great energy and skill. The sway of Cypselus was mild and popular; that of Periander, his son and successor, cruel and oppressive. But both unquestionably did much to advance the prosperity of the state. The numerous colonies planted in their time fully attest the growing strength of the city, which was now the first maritime power of Greece, and the centre through which passed the trade between Europe and Asia. Periander patronized letters and art, and welcomed to his court the poet Arion and the philosopher Anacharsis. By some he was classed among the seven sages of Greece. Psammetichus, the last of the despots of Corinth, was deposed by the Spartans. From

this time Corinth became the firm ally of Sparta, and a prominent member of the Peloponnesian confederacy. Its government became a mild and moderate aristocracy, and long enjoyed the greatest internal tranquillity. Its relations to Athens were also friendly, till the growing prosperity and power of the latter state subsequent to the Persian wars began to excite jealousy. Megara was long a subject of contention between them; and when Athens aided Corcyra against the mother city, Corinth exerted all her influence to induce the Peloponnesian confederacy to declare war against her powerful enemy. Thus commenced the Peloponnesian war, throughout which Corinth acted an important part; at first, indeed, she furnished almost the entire Peloponnesian fleet. When the peace of Nicias was concluded in 421 Corinth positively refused to ratify it, and after the defeat of the Athenian fleet at Ægospotamos urged the confederacy to raze Athens to the ground. But it was not long before the Spartans by their progress in power began to excite the jealousy of the other Grecian states; and the Corinthians united with the Bœotians, the Argives, and Athenians in a war against them. This contest, known in history as the Corinthian war, lasted from 394 to 387 B. C., when the peace of Antalcidas restored Corinth to the Lacedæmonian alliance, to which she remained faithful in the Theban war. About 346 Timophanes, attempting to establish tyranny, was killed by his brother Timoleon. After the battle of Chæronea the Macedonians took possession of the city, and stationed a strong garrison in the fortress of the Acrocorinthus; but after the defeat of Philip at Cynoscephalæ, in 197, Corinth, now declared free by the Romans, was again united to the Achæan league, which it originally joined in 243. At the head of the league, Corinth struck the last blow in defence of Greece, and then fell herself before the conquering legions of Rome, in the year 146. Mummius, the Roman consul, on entering the city as victor, put the men to death, and sold the women and children into slavery; he plundered the city of its precious treasures, and consigned it to the flames. From this time Corinth remained desolate for a century, when a colony was planted there by Julius Cæsar, which made it once more a prosperous city, the population rising to about 100,000. It was this Roman city which St. Paul visited a century later, which he made for almost two years his home, and where he founded that important church to which he afterward addressed two epistles. It continued for many years afterward to be the capital of Achaia, but finally fell before the devastating march of Alaric the Goth. In modern times, it was taken in 1458 by Mohammed II., transferred to the Venetians in 1687, and retaken by the Turks in 1715, who held it till 1823, when it passed into the possession of modern Greece. It was almost destroyed by an earthquake, Feb. 21, 1858.—Corinth in the day of Grecian greatness was distinguished more for commerce and the arts than for war. Architecture was early cultivated; sculptors and artists were honored and rewarded. It not only gave name to the most elaborate order of Grecian architecture, but also claimed the honor of having invented the art of painting. The Corinthian vases of terra cotta were among the finest in Greece; and such was their beauty that all the cemeteries of the city were ransacked by the colonists of Julius Cæsar, who sent them to Rome, where they brought enormous prices.

CORINTH, a village and the capital of Alcorn co., Mississippi, in the N. E. corner of the state, near the Tennessee line; pop. in 1870, 1,512, of whom 679 were colored. The village, being at the junction of the Memphis and Charleston and the Mobile and Ohio railroads, was a position of great strategical importance during the civil war, and had been early occupied by the confederates, who constructed there defensive works. It was still further strengthened by Gen. Beauregard after his retreat from the battle of Shiloh (April 6, 7, 1862). Gen. Halleck slowly followed him thither, and began those operations which at the time were designated as "the siege of Corinth." There was some fighting in the vicinity, at Farmington (May 21), and an attempt was made to flank Corinth and to cut the railroad S. of it, when the confederates evacuated the position, and retreated to Tupelo, pursued by Gen. Pope, though without material results. Corinth was now occupied by the Union troops, who enlarged the defensive works; and in the autumn it was held by Gen. Rosecrans with 20,000 men. The confederates, under Van Dorn and Price, with about 40,000 men, undertook to recapture the place. On Oct. 3 they attacked a strong outpost, which they carried, inflicting considerable loss; and on the 4th they endeavored to take Corinth by storm. The assault was made in two columns at different points. Each column gained some advantage at first; but when they reached the main defensive line both were swept back in utter rout. The whole confederate force fled in disorder, and were pursued for several miles with great slaughter, and without making a show of resistance. The entire Union loss was 315 killed, 1,812 wounded, and 232 prisoners, taken on the 3d. The confederate loss, as stated by Rosecrans, was 1,423 dead left behind and buried on the field, probably 5,000 wounded, and 2,248 prisoners, besides large quantities of small arms and ammunition.

CORINTH, Gulf of. See LEPANTO.

CORINTHIANS, Epistles to the, two canonical epistles of the New Testament, ascribed by the unanimous testimony of Christian antiquity to the apostle Paul, and addressed by him to the church which he had planted at Corinth about A. D. 52. The first was written from Ephesus between the years 56 and 58. It was designed to rebuke party divisions and consequent disorders which had arisen in the Corinthian church,

and also to give decisive judgments on certain practices, in regard to which the Corinthian converts had been affected by the proverbial immorality of the place. "Every one of you," Paul wrote to them (i. 12), "saith, I am of Paul, and I of Apollos, and I of Cephas, and I of Christ." Critics are almost unanimous in assuming that the party of Paul consisted of Christians who had been converted by him, chiefly from paganism; that the party of Apollos favored a Hellenico-philosophical tendency, and adopted Alexandrian forms of thought; and that the followers of Peter encouraged the tendency, common in the early churches, to engraft upon Christianity the ritual and restrictions of Judaism. But the greatest difference of opinion exists as to the party of Christ, most of the writers on the subject agreeing however so far as to assume that this party objected to the authority which Peter, Paul, and Apollos enjoyed with the other parties, and wished Christ to be regarded as the only head and authority of the church. In the first four chapters the apostle condemns their assumption of wisdom and disposition to glory in men, and urges them to unity on the foundation which is laid in Christ. In the remainder of the epistle he censures the church for having tolerated immoralities, condemns lawsuits between Christians before heathen judges, and, in answer to queries proposed to him by the Corinthians, gives various instructions concerning marriage and celibacy, the use of meat which had been offered to idols, the exercise of supernatural gifts, and the proprieties of public worship. The epistle closes with an elaborate exposition of the doctrine of the resurrection, and with general greetings. The second epistle has been much admired for its oratorical structure. The occasion of it seems to have been less special, at least less urgent; for he congratulates the disciples on the effect of his former censures, which had produced a godly sorrow and a revival of proper discipline. The burden of the second epistle is to commend them for their steadfastness, to rejoice in the conviction that he had labored with them in all sincerity and with all zeal, and to apologize to them for what might appear to be a foolish pride. It vindicates the character and effects of the religion which he had proclaimed, and his own dignity and authority as an apostle, apparently with reference to anti-Pauline influences which were still operating in the church. This second letter was probably written from Philippi, and about one year after the sending of the first. The Pauline origin of these two epistles is generally recognized even by the theologians of the critical school, and in the modern controversies on the life and true teachings of Jesus they are on that account of special importance. It is inferred from 1 Cor. v. 9 that our first epistle to the Corinthians was preceded by one which is now lost. An apocryphal book extant in the Armenian language (latest edition by Aucher, Venice, 1819) claims to be this epistle, and has found a defender in Rinck, who has translated it into German (1823). A number of exegetical writers, as Olshausen, Bleek, Neander, Ewald, Hilgenfeld, and Klöpper (*Exegetisch-kritische Untersuchungen über den zweiten Brief an die Korinther*, Göttingen, 1869), assume that another letter which is likewise lost was sent after the first and before the second; while Weisse and Hausrath consider the second epistle as a combination of two or three different epistles, and in particular the first seven chapters to have been written later than the last four.
